# The Kudla-Millson form via the Mathai-Quillen formalism 

Romain Branchereau

November 21, 2022

#### Abstract

In [6], Kudla and Millson constructed a $q$-form $\varphi_{K M}$ on an orthogonal symmetric space using Howe's differential operators. It is a crucial ingredient in their theory of theta lifting. This form can be seen as a Thom form of a real oriented vector bundle. In [9] Mathai and Quillen constructed a canonical Thom form and we show how to recover the Kudla-Millson form via their construction. A similar result was obtained by [3] for signature $(2, q)$ in case the symmetric space is hermitian and we extend it to an arbitrary signature.

## 1 Introduction

Let $(V, Q)$ be a quadratic space over $\mathbb{Q}$ of signature $(p, q)$ and let $G$ be its orthogonal group. Let $\mathbb{D}$ be the space of oriented negative $q$-planes in $V(\mathbb{R})$ and $\mathbb{D}^{+}$one of its connected components. It is a Riemannian manifold of dimension $p q$ and an open subset of the Grassmannian. The Lie group $G(\mathbb{R})^{+}$ is the connected component of the identity and acts transitively on $\mathbb{D}^{+}$. Hence we can identify $\mathbb{D}^{+}$with $G(\mathbb{R})^{+} / K$, where $K$ is a compact subgroup of $G(\mathbb{R})^{+}$and is isomorphic to $\mathrm{SO}(p) \times \mathrm{SO}(q)$. Moreover let $L$ be a lattice in $V(\mathbb{Q})$ and $\Gamma$ be a torsion free subgroup of $G(\mathbb{R})^{+}$preserving $L$.

For every vector $v$ in $V(\mathbb{R})$ there is a totally geodesic submanifold $\mathbb{D}_{v}^{+}$of codimension $q$ consisting of all the negative $q$-planes that are orthogonal to $v$. Let $\Gamma_{v}$ denote the stabilizer of $v$ in $\Gamma$. We can view $\Gamma_{v} \backslash \mathbb{D}^{+}$as a rank $q$ vector bundle over $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$, so that the natural embedding $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$in $\Gamma_{v} \backslash \mathbb{D}^{+}$is the zero section. In [6], Kudla and Millson constructed a closed $G(\mathbb{R})^{+}$-invariant differential form

$$
\begin{equation*}
\varphi_{K M} \in\left[\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes \mathscr{S}(V(\mathbb{R}))\right]^{G(\mathbb{R})^{+}} \tag{1.1}
\end{equation*}
$$

where $G(\mathbb{R})^{+}$acts on the Schwartz space $\mathscr{S}(V(\mathbb{R}))$ from the left by $(g f)(v):=f\left(g^{-1} v\right)$ and on $\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes$ $\mathscr{S}(V(\mathbb{R}))$ from the right by $g \cdot(\omega \otimes f):=g^{*} \omega \otimes\left(g^{-1} f\right)$. In particular $\varphi_{K M}(v)$ is a $\Gamma_{v}$-invariant form on $\mathbb{D}^{+}$. The main property of the Kudla-Millson form is its Thom form property: if $\omega$ in $\Omega_{c}^{p q-q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right)$ is a compactly supported form, then

$$
\begin{equation*}
\int_{\Gamma_{v} \backslash \mathbb{D}+} \varphi_{K M}(v) \wedge \omega=2^{-\frac{q}{2}} e^{-\pi Q(v, v)} \int_{\Gamma_{v} \backslash \mathbb{D}_{v}^{+}} \omega . \tag{1.2}
\end{equation*}
$$

Another way to state it is to say that in cohomology we have

$$
\begin{equation*}
\left[\varphi_{K M}(v)\right]=2^{-\frac{q}{2}} e^{-\pi Q(v, v)} \mathrm{PD}\left(\Gamma_{v} \backslash \mathbb{D}_{v}^{+}\right) \in H^{q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right) \tag{1.3}
\end{equation*}
$$

where $\operatorname{PD}\left(\Gamma_{v} \backslash \mathbb{D}_{v}^{+}\right)$denotes the Poincaré dual class to $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$.

Kudla-Millson theta lift. In order to motivate the interest in the Kudla-Millson form, let us briefly recall how it is used to construct a theta correspondence between certain cohomology classes and modular forms. Let $\omega$ be the Weil representation of $\mathrm{SL}_{2}(\mathbb{R})$ in $\mathscr{S}(V(\mathbb{R}))$. We extend it to a representation in $\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes \mathscr{S}(V(\mathbb{R}))$ by acting in the second factor of the tensor product. Building on the work of [10], Kudla and Millson [7, 8] used their differential form to construct the theta series

$$
\begin{equation*}
\Theta_{K M}(\tau):=y^{-\frac{p+q}{4}} \sum_{v \in L}\left(\omega\left(g_{\tau}\right) \varphi_{K M}\right)(v) \in \Omega^{q}\left(\mathbb{D}^{+}\right), \tag{1.4}
\end{equation*}
$$

where $\tau=x+i y$ is in $\mathbb{H}$ and $g_{\tau}$ is the matrix $\left(\begin{array}{cc}\sqrt{y} & x \sqrt{y}^{-1} \\ 0 & \sqrt{y}^{-1}\end{array}\right)$ in $\mathrm{SL}_{2}(\mathbb{R})$ that sends $i$ to $\tau$ by Möbius transformation. This form is $\Gamma$-invariant, closed and holomorphic in cohomology. Kudla and Millson showed that if we integrate this closed form on a compact $q$-cycle $C$ in $\mathcal{Z}_{q}\left(\Gamma \backslash \mathbb{D}^{+}\right)$, then

$$
\begin{equation*}
\int_{C} \Theta_{K M}(\tau)=c_{0}(C)+\sum_{n=1}^{\infty}\left\langle C, C_{2 n}\right\rangle e^{2 i \pi n \tau} \tag{1.5}
\end{equation*}
$$

is a modular form of weight $\frac{p+q}{2}$, where

$$
\begin{equation*}
C_{n}:=\sum_{\substack{v \in \Gamma \backslash L \\ Q(v, v)=n}} C_{v} \tag{1.6}
\end{equation*}
$$

and the special cycles $C_{v}$ are the images of the composition

$$
\begin{equation*}
\Gamma_{v} \backslash \mathbb{D}_{v}^{+} \hookrightarrow \Gamma_{v} \backslash \mathbb{D}^{+} \longrightarrow \Gamma \backslash \mathbb{D}^{+} . \tag{1.7}
\end{equation*}
$$

Thus, the Kudla-Millson theta series realizes a lift between the (co)-homology of $\Gamma \backslash \mathbb{D}^{+}$and the space of weight $\frac{p+q}{2}$ modular forms.

The result. Let $E$ be a $G(\mathbb{R})^{+}$-equivariant vector bundle of rank $q$ over $\mathbb{D}^{+}$and $E_{0}$ the image of the zero section. By the equivariance we also have a vector bundle $\Gamma_{v} \backslash E$ over $\Gamma_{v} \backslash \mathbb{D}^{+}$. The Thom class of the vector bundle is a characteristic class $\operatorname{Th}\left(\Gamma_{v} \backslash E\right)$ in $H^{q}\left(\Gamma_{v} \backslash E, \Gamma_{v} \backslash\left(E-E_{0}\right)\right)$ defined by the Thom isomorphism; see Subsection 3.6. A Thom form is a form representing the Thom class. It can be shown that the Thom class is also the Poincaré dual class to $\Gamma_{v} \backslash E_{0}$. Let $s_{v}: \Gamma_{v} \backslash \mathbb{D}^{+} \longrightarrow \Gamma_{v} \backslash E$ be a section whose zero locus is $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$, then

$$
\begin{equation*}
s_{v}^{*} \operatorname{Th}\left(\Gamma_{v} \backslash E\right) \in H^{q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}, \Gamma_{v} \backslash\left(\mathbb{D}^{+}-\mathbb{D}_{v}^{+}\right)\right) . \tag{1.8}
\end{equation*}
$$

Viewing it as a class in $H^{q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right)$it is the Poincaré dual class of $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$. Since the Poincaré dual class is unique, property (1.3) implies that

$$
\begin{equation*}
\left[\varphi_{K M}(v)\right]=2^{-\frac{q}{2}} e^{-\pi Q(v, v)} s_{v}^{*} \operatorname{Th}\left(\Gamma_{v} \backslash E\right) \in H^{q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right), \tag{1.9}
\end{equation*}
$$

on the level of cohomology.
For arbitrary oriented real metric vector bundles, Mathai and Quillen used the Chern-Weil theory to construct in [9] a canonical Thom forms on $E$. We denote by $U_{M Q}$ the canonical Thom form in $\Omega^{q}(E)$ of Mathai and Quillen. Since $U_{M Q}$ is $\Gamma$-invariant, it is also a Thom form for the bundle $\Gamma_{v} \backslash E$ for every vector $v$. The main result is the following.

Theorem. (Theorem 4.5) We have $\varphi_{K M}(v)=2^{-\frac{q}{2}} e^{-\pi Q(v, v)} s_{v}^{*} U_{M Q}$ in $\Omega^{q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right)$

For signature $(2, q)$, the spaces are hermitian and the result was obtained by a similar method in [3] using the work of Bismut-Gillet-Soulé.

## Acknowledgements

This project is part of my thesis and I thank my advisors Nicolas Bergeron and Luis Garcia for suggesting me this topic and for their support. I was funded from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement №754362 .

## 2 The Kudla-Millson form

### 2.1 The symmetric space $\mathbb{D}$

Let $(V, Q)$ be a rational quadratic space and let $(p, q)$ be the signature of $V(\mathbb{R})$. Let $e_{1}, \ldots, e_{p+q}$ be an orthogonal basis of $V(\mathbb{R})$ such that

$$
\begin{array}{rll}
Q\left(e_{\alpha}, e_{\alpha}\right)=1 & \text { for } & 1 \leq \alpha \leq p \\
Q\left(e_{\mu}, e_{\mu}\right)=-1 & \text { for } & p+1 \leq \mu \leq p+q . \tag{2.1}
\end{array}
$$

Note that we will always use letters $\alpha$ and $\beta$ for indices between 1 and $p$, and letters $\mu$ and $\nu$ for indices between $p+1$ and $p+q$. A plane $z$ in $V(\mathbb{R})$ is a negative plane if $\left.Q\right|_{z}$ is negative definite. Let

$$
\begin{equation*}
\mathbb{D}:=\{z \subset V(\mathbb{R}) \mid z \text { is an oriented negative plane of dimension } q\} \tag{2.2}
\end{equation*}
$$

be the set of negative oriented $q$-planes in $V(\mathbb{R})$. For each negative plane there are two possible orientations, yielding two connected components $\mathbb{D}^{+}$and $\mathbb{D}^{-}$of $\mathbb{D}$. Let $z_{0}$ in $\mathbb{D}^{+}$be the negative plane spanned by the vectors $e_{p+1}, \ldots, e_{p+q}$ together with a fixed orientation. The group $G(\mathbb{R})^{+}$ acts transitively on $\mathbb{D}^{+}$by sending $z_{0}$ to $g z_{0}$. Let $K$ be the stabilizer of $z_{0}$, which is isomorphic to $\mathrm{SO}(p) \times \mathrm{SO}(q)$. Thus we have an identification

$$
\begin{align*}
G(\mathbb{R})^{+} / K & \longrightarrow \mathbb{D}^{+} \\
g K & \longmapsto g z_{0} . \tag{2.3}
\end{align*}
$$

For $z$ in $\mathbb{D}^{+}$we denote by $g_{z}$ any element of $G(\mathbb{R})^{+}$sending $z_{0}$ to $z$.
For a positive vector $v$ in $V(\mathbb{R})$ we define

$$
\begin{equation*}
\mathbb{D}_{v}:=\left\{z \in \mathbb{D} \mid z \subset v^{\perp}\right\} \tag{2.4}
\end{equation*}
$$

It is a totally geodesic submanifold of $\mathbb{D}$ of codimension $q$. Let $\mathbb{D}_{v}^{+}$be the intersection of $\mathbb{D}_{v}$ with $\mathbb{D}^{+}$.
Let $z$ in $\mathbb{D}^{+}$be a negative plane. With respect to the orthogonal splitting of $V(\mathbb{R})$ as $z^{\perp} \oplus z$ the quadratic form splits as

$$
\begin{equation*}
Q(v, v)=\left.Q\right|_{z^{\perp}}(v, v)+\left.Q\right|_{z}(v, v) . \tag{2.5}
\end{equation*}
$$

We define the Siegel majorant at $z$ to be the positive definite quadratic form

$$
\begin{equation*}
Q_{z}^{+}(v, v):=\left.Q\right|_{z^{\perp}}(v, v)-\left.Q\right|_{z}(v, v) . \tag{2.6}
\end{equation*}
$$

### 2.2 The Lie algebras $\mathfrak{g}$ and $\mathfrak{k}$

Let

$$
\begin{gather*}
\mathfrak{g}:=\left\{\left.\left(\begin{array}{cc}
A & x \\
{ }^{t} x & B
\end{array}\right) \right\rvert\, A \in \mathfrak{s o}\left(z_{0}^{\perp}\right), B \in \mathfrak{s o}\left(z_{0}\right), x \in \operatorname{Hom}\left(z_{0}, z_{0}^{\perp}\right)\right\},  \tag{2.7}\\
\mathfrak{k}:=\left\{\left.\left(\begin{array}{cc}
A & 0 \\
0 & B
\end{array}\right) \right\rvert\, A \in \mathfrak{s o}\left(z_{0}^{\perp}\right), B \in \mathfrak{s o}\left(z_{0}\right)\right\} \tag{2.8}
\end{gather*}
$$

be the Lie algebras of $G(\mathbb{R})^{+}$and $K$ where $\mathfrak{s o}\left(z_{0}\right)$ is equal to $\mathfrak{s o}(q)$. The latter is the space of skewsymmetric $q$ by $q$ matrices. Similarly we have $\mathfrak{s o}\left(z_{0}^{\perp}\right)$ equals $\mathfrak{s o}(p)$. Hence we have a decomposition of $\mathfrak{k}$ as $\mathfrak{s o}\left(z_{0}^{\perp}\right) \oplus \mathfrak{s o}\left(z_{0}\right)$ that is orthogonal with respect to the Killing form. Let $\epsilon$ be the Lie algebra involution of $\mathfrak{g}$ mapping $X$ to $-{ }^{t} X$. The +1 -eigenspace of $\epsilon$ is $\mathfrak{k}$ and the - 1 -eigenspace is

$$
\mathfrak{p}:=\left\{\left.\left(\begin{array}{cc}
0 & x  \tag{2.9}\\
{ }^{t} x & 0
\end{array}\right) \right\rvert\, x \in \operatorname{Hom}\left(z_{0}, z_{0}^{\perp}\right)\right\} .
$$

We have a decomposition of $\mathfrak{g}$ as $\mathfrak{k} \oplus \mathfrak{p}$ and it is orthogonal with respect to the Killing form. We can identify $\mathfrak{p}$ with $\mathfrak{g} / \mathfrak{k}$. Since $\epsilon$ is a Lie algebra automorphism we have that

$$
\begin{equation*}
[\mathfrak{p}, \mathfrak{p}] \subset \mathfrak{k}, \quad[\mathfrak{k}, \mathfrak{p}] \subset \mathfrak{p} \tag{2.10}
\end{equation*}
$$

We identify the tangent space of $\mathbb{D}^{+}$at $e K$ with $\mathfrak{p}$ and the tangent bundle $T \mathbb{D}^{+}$with $G(\mathbb{R})^{+} \times_{K} \mathfrak{p}$ where $K$ acts on $\mathfrak{p}$ by the Ad-representation. We have an isomorphism

$$
\begin{align*}
T: \wedge^{2} V(\mathbb{R}) & \longrightarrow \mathfrak{g} \\
\quad e_{i} \wedge e_{j} & \longmapsto T\left(e_{i} \wedge e_{j}\right) e_{k}:=Q\left(e_{i}, e_{k}\right) e_{j}-Q\left(e_{j}, e_{k}\right) e_{i} . \tag{2.11}
\end{align*}
$$

A basis of $\mathfrak{g}$ is given by the set of matrices

$$
\begin{equation*}
\left\{X_{i j}:=T\left(e_{i} \wedge e_{j}\right) \in \mathfrak{g} \mid 1<i<j<p+q\right\} \tag{2.12}
\end{equation*}
$$

and we denote by $\omega_{i j}$ its dual basis in the dual space $\mathfrak{g}^{*}$. Let $E_{i j}$ be the elementary matrix sending $e_{i}$ to $e_{j}$ and the other $e_{k}$ 's to 0 . Then $\mathfrak{p}$ is spanned by the matrices

$$
\begin{equation*}
X_{\alpha \mu}=E_{\alpha \mu}+E_{\mu \alpha} \tag{2.13}
\end{equation*}
$$

and $\mathfrak{k}$ is spanned by the matrices

$$
\begin{align*}
X_{\alpha \beta} & =E_{\alpha \beta}-E_{\beta \alpha} \\
X_{\nu \mu} & =-E_{\nu \mu}+E_{\mu \nu} . \tag{2.14}
\end{align*}
$$

### 2.3 Poincaré duals

Let $M$ be an arbitrary $m$-dimensional real orientable manifold without boundary. The integration map yields a non-degenerate pairing [2, Theorem. 5.11]

$$
\begin{align*}
H^{q}(M) \otimes_{\mathbb{R}} H_{c}^{m-q}(M) & \longrightarrow \mathbb{R} \\
{[\omega] \otimes[\eta] } & \longmapsto \int_{M} \omega \wedge \eta, \tag{2.15}
\end{align*}
$$

where $H_{c}(M)$ denotes the cohomology of compactly supported forms on $M$. This yields an isomorphism between $H^{q}(M)$ and the dual $H_{c}^{m-q}(M)^{*}=\operatorname{Hom}\left(H_{c}^{m-q}(M), \mathbb{R}\right)$. If $C$ is an immersed submanifold of codimension $q$ in $M$ then $C$ defines a linear functional on $H_{c}^{m-q}(M)$ by

$$
\begin{equation*}
\omega \longmapsto \int_{C} \omega \tag{2.16}
\end{equation*}
$$

Since we have an isomorphism between $H_{c}^{m-q}(M)^{*}$ and $H^{q}(M)$ there is a unique cohomology class $\mathrm{PD}(C)$ in $H^{q}(M)$ representing this functional i.e.

$$
\begin{equation*}
\int_{M} \omega \wedge \mathrm{PD}(C)=\int_{C} \omega \tag{2.17}
\end{equation*}
$$

for every class $[\omega]$ in $H_{c}^{m-q}(M)$. We call $\operatorname{PD}(C)$ the Poincaré dual class to $C$, and any differential form representing the cohomology class $\mathrm{PD}(C)$ a Poincaré dual form to $C$.

### 2.4 The Kudla-Millson form

The tangent plane at the identity $T_{e K} \mathbb{D}^{+}$can be identified with $\mathfrak{p}$ and the cotangent bundle $\left(T \mathbb{D}^{+}\right)^{*}$ with $G(\mathbb{R})^{+} \times{ }_{K} \mathfrak{p}^{*}$, where $K$ acts on $\mathfrak{p}^{*}$ by the dual of the Ad-representation. The basis $e_{1}, \ldots, e_{p+q}$ identifies $V(\mathbb{R})$ with $\mathbb{R}^{p+q}$. With respect to this basis the Siegel majorant at $z_{0}$ is given by

$$
\begin{equation*}
Q_{z_{0}}^{+}(v, v):=\sum_{i=1}^{p+q} x_{i}^{2} \tag{2.18}
\end{equation*}
$$

Recall that $G(\mathbb{R})^{+}$acts on $\mathscr{S}\left(\mathbb{R}^{p+q}\right)$ from the left by $(g \cdot f)(v)=f\left(g^{-1} v\right)$ and on $\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right)$ from the right by $g \cdot(\omega \otimes f):=g^{*} \omega \otimes\left(g^{-1} f\right)$. We have an isomorphism

$$
\begin{align*}
{\left[\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right)\right]^{G(\mathbb{R})^{+}} } & \longrightarrow\left[\bigwedge^{q} \mathfrak{p}^{*} \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right)\right]^{K} \\
\varphi & \longrightarrow \varphi_{e} \tag{2.19}
\end{align*}
$$

by evaluating $\varphi$ at the basepoint $e K$ in $G(\mathbb{R})^{+} / K$, corresponding to the point $z_{0}$ in $\mathbb{D}^{+}$. We define the Howe operator

$$
\begin{equation*}
D: \bigwedge^{\bullet} \mathfrak{p}^{*} \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right) \longrightarrow \bigwedge^{\bullet+q} \mathfrak{p}^{*} \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right) \tag{2.20}
\end{equation*}
$$

by

$$
\begin{equation*}
D:=\frac{1}{2^{q}} \prod_{\mu=p+1}^{p+q} \sum_{\alpha=1}^{p} A_{\alpha \mu} \otimes\left(x_{\alpha}-\frac{1}{2 \pi} \frac{\partial}{\partial x_{\alpha}}\right) \tag{2.21}
\end{equation*}
$$

where $A_{\alpha \mu}$ denotes left multiplication by $\omega_{\alpha \mu}$. The Kudla-Millson form is defined by applying $D$ to the Gaussian:

$$
\begin{equation*}
\varphi_{K M}(v)_{e}:=D \exp \left(-\pi Q_{z_{0}}^{+}(v, v)\right) \in \bigwedge^{q} \mathfrak{p}^{*} \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right) \tag{2.22}
\end{equation*}
$$

Kudla and Millson showed that this form is $K$-invariant. Hence by the isomorphism (2.19) we get a form

$$
\begin{equation*}
\varphi_{K M} \in\left[\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right)\right]^{G(\mathbb{R})^{+}} \tag{2.23}
\end{equation*}
$$

In particular it is $\Gamma_{v}$-invariant and defines a form on $\Gamma_{v} \backslash \mathbb{D}^{+}$. It is also closed and satisfies the Thom form property: for every compactly supported form $\omega$ in $\Omega_{c}^{p q-q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right)$we have

$$
\begin{equation*}
\int_{\Gamma_{v} \backslash \mathbb{D}^{+}} \omega \wedge \varphi_{K M}(v)=2^{-\frac{q}{2}} e^{-\pi Q(v, v)} \int_{\Gamma_{v} \backslash \mathbb{D}_{v}^{+}} \omega . \tag{2.24}
\end{equation*}
$$

## 3 The Mathai-Quillen formalism

We begin by recalling a few facts about principal bundles, connections and associated vector bundles. For more details we refer to [1] and [5]. The Mathai-Quillen form is defined in Subsection 3.7 following [1]; see also [4].

### 3.1 K-principal bundles and principal connections

Let $K$ be $\mathrm{SO}(p) \times \mathrm{SO}(q)$ as before and $P$ be a smooth principal $K$-bundle. Let

$$
\begin{array}{r}
R: K \times P \longrightarrow P \\
(k, p) \longmapsto R_{k}(p) \tag{3.1}
\end{array}
$$

be the smooth right action of $K$ on $P$ and

$$
\begin{equation*}
\pi: P \longrightarrow P / K \tag{3.2}
\end{equation*}
$$

the projection map. For a fixed $p$ in $P$ consider the map

$$
\begin{align*}
R_{p}: K & \longrightarrow P \\
k & \longmapsto R_{k}(p) . \tag{3.3}
\end{align*}
$$

Let $V_{p} P$ be the image of the derivative at the identity

$$
\begin{equation*}
d_{e} R_{p}: \mathfrak{k} \longrightarrow T_{p} P \tag{3.4}
\end{equation*}
$$

which is injective. It coincides with the kernel of the differential $d_{p} \pi$. A vector in $V_{p} P$ is called a vertical vector. Using this map we can view a vector $X$ in $\mathfrak{k}$ as a vertical vector field on $P$. The space $P$ can a priori be arbitrary, but in our case we will consider either

1. $P$ is $G(\mathbb{R})^{+}$and $R_{k}$ the natural right action sending $g$ to $g k$. Then $P / K$ can be identified with $\mathbb{D}^{+}$,
2. $P$ is $G(\mathbb{R})^{+} \times z_{0}$ and the action $R_{k}$ maps $(g, w)$ to $\left(g k, k^{-1} w\right)$. In this case $P / K$ can be identified with $G(\mathbb{R})^{+} \times_{K} z_{0}$. It is the vector bundle associated to the principal bundle $G(\mathbb{R})^{+}$as defined below.

A principal $K$-connection on $P$ is a 1 -form $\theta_{P}$ in $\Omega^{1}(P, \mathfrak{k})$ such that

- $\iota_{X} \theta_{P}=X \quad$ for any $X$ in $\mathfrak{k}$,
- $R_{k}^{*} \theta_{P}=A d\left(k^{-1}\right) \theta_{P} \quad$ for any $k$ in $K$,
where $\iota_{X}$ is the interior product

$$
\begin{align*}
& \iota_{X}: \Omega^{k}(P) \longrightarrow \Omega^{k}(P) \\
& \quad \omega \longmapsto\left(\iota_{X} \omega\right)\left(X_{1}, \ldots, X_{p-1}\right):=\omega\left(X, X_{1}, \ldots, X_{p-1}\right) . \tag{3.5}
\end{align*}
$$

and we view $X$ as a vector field on $P$. Geometrically these conditions imply that the kernel of $\theta_{P}$ defines a horizontal subspace of $T P$ that we denote by $H P$. It is a complement to the vertical subspace i.e. we get a splitting of $T_{p} P$ as $V_{p} P \oplus H_{p} P$.

Let $\mathfrak{g}$ be the Lie algebra of $G(\mathbb{R})^{+}$and let $p$ be the orthogonal projection from $\mathfrak{g}$ on $\mathfrak{k}$. After identifying $\mathfrak{g}^{*}$ with the space $\Omega^{1}\left(G(\mathbb{R})^{+}\right)^{G(\mathbb{R})^{+}}$of $G(\mathbb{R})^{+}$-invariant forms we define a natural 1-form

$$
\begin{equation*}
\sum_{1 \leq i<j \leq p+q} \omega_{i j} \otimes X_{i j} \in \Omega^{1}\left(G(\mathbb{R})^{+}\right) \otimes \mathfrak{g} \tag{3.6}
\end{equation*}
$$

called the Maurer-Cartan form, where $X_{i j}$ is the basis of $\mathfrak{g}$ defined earlier and $\omega_{i j}$ its dual in $\mathfrak{g}^{*}$. After projection onto $\mathfrak{k}$ we get a form

$$
\begin{equation*}
\theta:=p\left(\sum_{1 \leq i<j \leq p+q} \omega_{i j} \otimes X_{i j}\right) \in \Omega^{1}\left(G(\mathbb{R})^{+}\right) \otimes \mathfrak{k} \tag{3.7}
\end{equation*}
$$

where we identify $\Omega^{1}\left(G(\mathbb{R})^{+}, \mathfrak{k}\right)$ with $\Omega^{1}\left(G(\mathbb{R})^{+}\right) \otimes \mathfrak{k}$. A direct computation shows that it is a principal $K$-connection on $P$ when $P$ is $G(\mathbb{R})^{+}$.

If $P$ is $G(\mathbb{R})^{+} \times z_{0}$ then the projection

$$
\begin{equation*}
\pi: G(\mathbb{R})^{+} \times z_{0} \longrightarrow G(\mathbb{R})^{+} \tag{3.8}
\end{equation*}
$$

induces a pullback map

$$
\begin{equation*}
\pi^{*}: \Omega^{1}\left(G(\mathbb{R})^{+}\right) \longrightarrow \Omega^{1}\left(G(\mathbb{R})^{+} \times z_{0}\right) \tag{3.9}
\end{equation*}
$$

The form

$$
\begin{equation*}
\widetilde{\theta}:=\pi^{*} \theta \in \Omega^{1}\left(G(\mathbb{R})^{+} \times z_{0}\right) \otimes \mathfrak{k} \tag{3.10}
\end{equation*}
$$

is a principal connection on $G(\mathbb{R})^{+} \times z_{0}$.

### 3.2 The associated vector bundles

Since $z_{0}$ is preserved by $K$ we have an orthogonal $K$-representation

$$
\begin{align*}
\rho: K & \longrightarrow \mathrm{SO}\left(z_{0}\right) \\
\quad k & \longmapsto \rho(k) w:=\left.k\right|_{z_{0}} w, \tag{3.11}
\end{align*}
$$

where we will usually simply write $k w$ instead of $\left.k\right|_{z_{0}} w$. We can consider the associated vector bundle $P \times_{K} z_{0}$ which is the quotient of $P \times z_{0}$ by $K$, where $K$ acts by sending $(p, w)$ to $\left(R_{k}(p), \rho(k)^{-1} w\right)$. Hence an element $[p, w]$ of $P \times_{K} z_{0}$ is an equivalence class where the equivalence relation identifies $(p, w)$ with $\left(R_{k}(p), \rho(k)^{-1} w\right)$. This is a vector bundle over $P / K$ with projection map sending $[p, w]$ to $\pi(p)$. Let $\Omega^{i}\left(P / K, P \times_{K} z_{0}\right)$ be the space of $i$-forms valued in $P \times_{K} z_{0}$, when $i$ is zero it is the space of smooth sections of the associated bundle.

In the two cases of interest to us we define

$$
\begin{align*}
& E:=G(\mathbb{R})^{+} \times_{K} z_{0} \\
& \widetilde{E}:=\left(G(\mathbb{R})^{+} \times z_{0}\right) \times_{K} z_{0} \tag{3.12}
\end{align*}
$$

Note that in both cases $P$ admits a left action of $G(\mathbb{R})^{+}$and that the associated vector bundles are $G(\mathbb{R})^{+}$-equivariant. Morever it is a Euclidean bundle, equipped with the inner product

$$
\begin{equation*}
\langle v, w\rangle:=-\left.Q\right|_{z_{0}}(v, w) \tag{3.13}
\end{equation*}
$$

on the fiber. Let $\Omega^{i}\left(P, z_{0}\right)$ be the space of $z_{0}$-valued differential $i$-forms on $P$. A differential form $\alpha$ in $\Omega^{i}\left(P, z_{0}\right)$ is said to be horizontal if $\iota_{X} \alpha$ vanishes for all vertical vector fields $X$. There is a left action of $K$ on a differential form $\alpha$ in $\Omega^{i}\left(P, z_{0}\right)$ defined by

$$
\begin{equation*}
k \cdot \alpha:=\rho(k)\left(R_{k}^{*} \alpha\right) \tag{3.14}
\end{equation*}
$$

and $\alpha$ is $K$-invariant if it satisfies $k \cdot \alpha=\alpha$ for any $k$ in $K$ i.e. we have $R_{k}^{*} \alpha=\rho\left(k^{-1}\right) \alpha$. We write $\Omega^{i}\left(P, z_{0}\right)^{K}$ for the space of $K$-invariant $z_{0}$-valued forms on $P$. Finally a form that is horizontal and $K$-invariant is called a basic form and the space of such forms is denoted by $\Omega^{i}\left(P, z_{0}\right)_{\text {bas }}$.

Let $X_{1}, \ldots, X_{N}$ be tangent vectors of $P / K$ at $\pi(p)$ and $\widetilde{X}_{i}$ be tangent vectors of $P$ at $p$ that satisfy $d_{p} \pi\left(\widetilde{X}_{i}\right)=X_{i}$. There is a map

$$
\begin{align*}
\Omega^{i}\left(P, z_{0}\right)_{b a s} & \longrightarrow \Omega^{i}\left(P / K, P \times_{K} z_{0}\right) \\
\alpha & \longmapsto \omega_{\alpha} \tag{3.15}
\end{align*}
$$

defined by

$$
\begin{equation*}
\left.\omega_{\alpha}\right|_{\pi(p)}\left(X_{1} \wedge \cdots \wedge X_{N}\right)=\left.\alpha\right|_{p}\left(\widetilde{X}_{1} \wedge \cdots \wedge \widetilde{X}_{N}\right) \tag{3.16}
\end{equation*}
$$

Proposition 3.1. The map is well-defined and yields an isomorphism between $\Omega^{i}\left(P / K, P \times_{K} z_{0}\right)$ and $\Omega^{i}\left(P, z_{0}\right)_{b a s}$. In particular if $z_{0}$ is 1-dimensional then $\Omega^{i}(P / K)$ is isomorphic to $\Omega^{i}(P)_{b a s}$.

Proof. In the case where $i$ is zero the horizontally condition is vacuous and the isomorphism simply identifies $\Omega^{0}\left(P / K, P \times_{K} z_{0}\right)$ with $\Omega^{0}\left(P, z_{0}\right)^{K}$. We have a map

$$
\begin{align*}
\Omega^{0}\left(P, z_{0}\right)^{K} & \longrightarrow \Omega^{0}\left(P / K, P \times_{K} z_{0}\right) \\
f & \longmapsto s_{f}(\pi(p)):=[p, f(p)] \tag{3.17}
\end{align*}
$$

which is well defined since

$$
\begin{equation*}
f\left(R_{k}(p)\right)=\rho(k)^{-1} f(p) \tag{3.18}
\end{equation*}
$$

Conversely every smooth section $s$ in $\Omega^{0}\left(P / K, P \times_{K} z_{0}\right)$ is given by

$$
\begin{equation*}
s(\pi(p))=\left[p, f_{s}(p)\right] \tag{3.19}
\end{equation*}
$$

for some smooth function $f_{s}$ in $\Omega^{0}\left(P, z_{0}\right)^{K}$. The map sending $s$ to $f_{s}$ is inverse to the previous one. The proof is similar for positive $i$.

### 3.3 Covariant derivatives

A covariant derivative on the vector bundle $P \times{ }_{K} z_{0}$ is a differential operator

$$
\begin{equation*}
\nabla_{P}: \Omega^{0}\left(P / K, P \times_{K} z_{0}\right) \longrightarrow \Omega^{1}\left(P / K, P \times_{K} z_{0}\right) \tag{3.20}
\end{equation*}
$$

such that for every smooth function $f$ in $C^{\infty}(P / K)$ we have

$$
\begin{equation*}
\nabla_{P}(f s)=d f \otimes s+f \nabla_{P}(s) . \tag{3.21}
\end{equation*}
$$

The inner product on $P \times_{K} z_{0}$ defines a pairing

$$
\begin{align*}
\Omega^{i}\left(P / K, P \times_{K} z_{0}\right) \times \Omega^{j}\left(P / K, P \times_{K} z_{0}\right) & \longrightarrow \Omega^{i+j}(P / K) \\
\left(\omega_{1} \otimes s_{1}, \omega_{2} \otimes s_{2}\right) & \longmapsto\left\langle\omega_{1} \otimes s_{1}, \omega_{2} \otimes s_{2}\right\rangle=\omega_{1} \wedge \omega_{2}\left\langle s_{1}, s_{2}\right\rangle, \tag{3.22}
\end{align*}
$$

and we say that the derivative is compatible with the metric if

$$
\begin{equation*}
d\left\langle s_{1}, s_{2}\right\rangle=\left\langle\nabla_{P} s_{1}, s_{2}\right\rangle+\left\langle s_{1}, \nabla_{P} s_{2}\right\rangle \tag{3.23}
\end{equation*}
$$

for any two sections $s_{1}$ and $s_{2}$ in $\Omega^{0}\left(P / K, P \times_{K} z_{0}\right)$. There is a covariant derivative that is induced by a principal connection $\theta_{P}$ in $\Omega^{1}(P) \otimes \mathfrak{k}$ as follows. The derivative of the representation gives a map

$$
\begin{equation*}
d \rho: \mathfrak{k} \longrightarrow \mathfrak{s o}\left(z_{0}\right) \subset \operatorname{End}\left(z_{0}\right), \tag{3.24}
\end{equation*}
$$

which we also denote by $\rho$ by abuse of notation. Note that for the representation (3.11) this is simply the map

$$
\begin{align*}
\rho: \mathfrak{k} & \longrightarrow \mathfrak{s o}\left(z_{0}\right) \\
X & \left.\longmapsto X\right|_{z_{0}} \tag{3.25}
\end{align*}
$$

since $\mathfrak{k}$ splits as $\mathfrak{s o}\left(z_{0}^{\perp}\right) \oplus \mathfrak{s o}\left(z_{0}\right)$. Composing the principal connection with $\rho$ defines an element

$$
\begin{equation*}
\rho\left(\theta_{P}\right) \in \Omega^{1}\left(P, \mathfrak{s o}\left(z_{0}\right)\right) . \tag{3.26}
\end{equation*}
$$

In particular, if $s$ is a section of $P \times_{K} z_{0}$ then we can identify it with a $K$-invariant smooth map $f_{s}$ in $\Omega^{0}\left(P, z_{0}\right)^{K}$. Since $\rho\left(\theta_{P}\right)$ is a $\mathfrak{s o}\left(z_{0}\right)$-valued form and $\mathfrak{s o}\left(z_{0}\right)$ is a subspace of $\operatorname{End}\left(z_{0}\right)$ we can define

$$
\begin{equation*}
d f_{s}+\rho\left(\theta_{P}\right) \cdot f_{s} \in \Omega^{1}\left(P, z_{0}\right) \tag{3.27}
\end{equation*}
$$

Lemma 3.2. The form $d f_{s}+\rho\left(\theta_{P}\right) \cdot f_{s}$ is basic, hence gives a $P \times_{K} z_{0}$-valued form on $P / K$. Thus $d+\rho\left(\theta_{P}\right)$ defines a covariant derivative on $P \times_{K} z_{0}$. Moreover, it is compatible with the metric.

Proof. See [1, p. 24]. For the compatibility with the metric, it follows from the fact that the connection $\rho\left(\theta_{P}\right)$ is valued in $\mathfrak{s o}\left(z_{0}\right)$ that

$$
\begin{equation*}
\left\langle\rho\left(\theta_{P}\right) f_{s_{1}}, f_{s_{2}}\right\rangle+\left\langle f_{s_{1}}, \rho\left(\theta_{P}\right) f_{s_{2}}\right\rangle=0 . \tag{3.28}
\end{equation*}
$$

Hence if we denote by $\nabla_{P}$ is the covariant derivative defined by $d+\rho\left(\theta_{P}\right)$ then

$$
\begin{equation*}
\left\langle\nabla_{P} s_{1}, s_{2}\right\rangle+\left\langle s_{1}, \nabla_{P} s_{2}\right\rangle=\left\langle d f_{s_{1}}, f_{s_{2}}\right\rangle+\left\langle f_{s_{1}}, d f_{s_{2}}\right\rangle=d\left\langle f_{s_{1}}, f_{s_{2}}\right\rangle=d\left\langle s_{1}, s_{2}\right\rangle . \tag{3.29}
\end{equation*}
$$

Let us denote by $\nabla_{P}$ the covariant derivative $d+\rho\left(\theta_{P}\right)$. It can be extended to a map

$$
\begin{equation*}
\nabla_{P}: \Omega^{i}\left(P / K, P \times_{K} z_{0}\right) \longrightarrow \Omega^{i+1}\left(P / K, P \times_{K} z_{0}\right) \tag{3.30}
\end{equation*}
$$

by setting

$$
\begin{equation*}
\nabla_{P}(\omega \otimes s):=d \omega \otimes s+(-1)^{i} \omega \wedge \nabla_{P}(s) \tag{3.31}
\end{equation*}
$$

where

$$
\begin{equation*}
\omega \otimes s \in \Omega^{i}(P / K) \otimes \Omega^{0}\left(P / K, P \times_{K} z_{0}\right) \simeq \Omega^{i}\left(P / K, P \times_{K} z_{0}\right) \tag{3.32}
\end{equation*}
$$

We define the curvature $R_{P}$ in $\Omega^{2}(P, \mathfrak{k})$ by

$$
\begin{equation*}
R_{P}(X, Y):=\left[\theta_{P}(X), \theta_{P}(Y)\right]-\theta_{P}([X, Y]) \tag{3.33}
\end{equation*}
$$

for two vector fields $X$ and $Y$ on $P$. It is basic by [1, Proposition. 1.13] and composing with $\rho$ gives an element

$$
\begin{equation*}
\rho\left(R_{P}\right) \in \Omega^{2}\left(P, \mathfrak{s o}\left(z_{0}\right)\right)_{b a s} \tag{3.34}
\end{equation*}
$$

so that we can view it as an element in $\Omega^{2}\left(P / K, P \times_{K} \mathfrak{s o}\left(z_{0}\right)\right)$ where $K$ acts on $\mathfrak{s o}\left(z_{0}\right)$ by the Adrepresentation. For a section $s$ in $\Omega^{0}\left(P / K, P \times_{K} z_{0}\right)$ we have [1, Proposition. 1.15]

$$
\begin{equation*}
\nabla_{P}^{2} s=\rho\left(R_{p}\right) s \in \Omega^{2}\left(P / K, P \times_{K} z_{0}\right) \tag{3.35}
\end{equation*}
$$

From now on we denote by $\nabla$ and $\widetilde{\nabla}$ the covariant derivatives on $E$ and $\widetilde{E}$ associated to $\theta$ and $\widetilde{\theta}$ defined in (3.7) and (3.10). Let $R$ and $\widetilde{R}$ be their respectives curvatures.

### 3.4 Pullback of bundles

The pullback of $E$ by the projection map gives a canonical bundle

$$
\begin{equation*}
\pi^{*} E:=\left\{\left(e, e^{\prime}\right) \in E \times E \mid \pi(e)=\pi\left(e^{\prime}\right)\right\} \tag{3.36}
\end{equation*}
$$

over $E$. We have the following diagram

The projection induces a pullback of the sections

$$
\begin{equation*}
\pi^{*}: \Omega^{i}(\mathbb{D}, E) \longrightarrow \Omega^{i}(E, \widetilde{E}) \tag{3.38}
\end{equation*}
$$

We can also pullback the covariant derivative $\nabla$ to a covariant derivative

$$
\begin{equation*}
\pi^{*} \nabla: \Omega^{0}\left(E, \pi^{*} E\right) \longrightarrow \Omega^{1}\left(E, \pi^{*} E\right) \tag{3.39}
\end{equation*}
$$

on $\pi^{*} E$. It is characterized by the property

$$
\begin{equation*}
\left(\pi^{*} \nabla\right)\left(\pi^{*} s\right)=\pi^{*}(\nabla s) \tag{3.40}
\end{equation*}
$$

Proposition 3.3. The bundles $\widetilde{E}$ and $\pi^{*} E$ are isomorphic, and this isomorphism identifies $\widetilde{\nabla}$ and $\pi^{*} \nabla$.

Proof. By definition $\left(\left[g_{1}, w_{1}\right],\left[g_{2}, w_{2}\right]\right)$ are elements of $\pi^{*} E$ if and only if $g_{1}^{-1} g_{2}$ is in $K$. We have a $G(\mathbb{R})^{+}$-equivariant morphism

$$
\begin{align*}
\pi^{*} E & \longrightarrow \widetilde{E} \\
\left(\left[g_{1}, w_{1}\right],\left[g_{2}, w_{2}\right]\right) & \longrightarrow\left[\left(g_{1}, g_{1}^{-1} g_{2} w_{2}\right), w_{1}\right] . \tag{3.41}
\end{align*}
$$

This map is well defined and has as inverse

$$
\begin{align*}
\widetilde{E} & \longrightarrow \pi^{*} E \\
{\left[\left(g, w_{1}\right), w_{2}\right] } & \longrightarrow\left(\left[g, w_{2}\right],\left[g, w_{1}\right]\right) . \tag{3.42}
\end{align*}
$$

The second statement follows from the fact that $\tilde{\theta}$ is $\pi^{*} \theta$.

### 3.5 A few operations on the vector bundles

We extend the $K$-representation $z_{0}$ to $\bigwedge^{j} z_{0}$ by

$$
\begin{equation*}
k\left(w_{1} \wedge \cdots \wedge w_{j}\right)=\left(k w_{1}\right) \wedge \cdots \wedge\left(k w_{j}\right) \tag{3.43}
\end{equation*}
$$

We consider the bundles $P \times_{K} \wedge^{j} z_{0}$ and $P \times_{K} \wedge z_{0}$ over $P / K$, where $\bigwedge z_{0}$ is defined as $\bigoplus_{i} \bigwedge^{i} z_{0}$. Denote the space of differential forms valued in $P \times_{K} \wedge^{j} z_{0}$ by

$$
\begin{equation*}
\Omega_{P}^{i, j}:=\Omega_{P}^{i}\left(P / K, P \times_{K} \wedge^{j} z_{0}\right)=\Omega_{P}^{i}(P / K) \otimes \Omega^{0}\left(P / K, P \times_{K} \wedge^{j} z_{0}\right) \tag{3.44}
\end{equation*}
$$

The total space of differential forms

$$
\begin{equation*}
\Omega\left(P / K, P \times_{K} \wedge z_{0}\right)=\bigoplus_{i, j} \Omega_{P}^{i, j} \tag{3.45}
\end{equation*}
$$

is an (associative) bigraded $C^{\infty}(P / K)$-algebra where the product is defined by

$$
\begin{align*}
\wedge: \Omega_{P}^{i, j} \times \Omega_{P}^{k, l} & \longrightarrow \Omega_{P}^{i+k, j+l} \\
(\omega \otimes s, \eta \otimes t) & \longmapsto(\omega \otimes s) \wedge(\eta \otimes t):=(-1)^{j k}(\omega \wedge \eta) \otimes(s \wedge t) \tag{3.46}
\end{align*}
$$

This algebra structure allows us to define an exponential map by

$$
\begin{align*}
\exp : \Omega\left(P / K, P \times_{K} \wedge z_{0}\right) & \longrightarrow \Omega\left(P / K, P \times_{K} \wedge z_{0}\right) \\
\omega & \longmapsto \exp (\omega):=\sum_{k \geq 0} \frac{\omega^{k}}{k!} \tag{3.47}
\end{align*}
$$

where $\omega^{k}$ is the $k$-fold wedge product $\omega \wedge \cdots \wedge \omega$.
Remark 3.1. Suppose that $\omega$ and $\eta$ commute. Then the binomial formula

$$
\begin{equation*}
(\omega+\eta)^{k}=\sum_{l=0}^{k}\binom{k}{l} \omega^{l} \eta^{k-l} \tag{3.48}
\end{equation*}
$$

holds and one can show that $\exp (\omega+\eta)=\exp (\omega)+\exp (\eta)$ in the same way as for the real exponential map. In particular the diagonal subalgebra $\bigoplus \Omega_{P}^{i, i}$ is a commutative since for two forms $\omega$ and $\eta$ in $\Omega_{P}$ we have

$$
\begin{equation*}
\omega \wedge \eta=(-1)^{\operatorname{deg}(\omega)+\operatorname{deg}(\eta)} \eta \wedge \omega \tag{3.49}
\end{equation*}
$$

and similarly for two sections sand $t$ in $\Omega^{0}\left(P / K, P \times{ }_{K} z_{0}\right)$.

The inner product $\langle-,-\rangle$ on $z_{0}$ can be extended to an inner product on $\bigwedge z_{0}$ by

$$
\left\langle v_{1} \wedge \cdots \wedge v_{k}, w_{1} \wedge \cdots \wedge w_{l}\right\rangle:= \begin{cases}0 & \text { if } k \neq l  \tag{3.50}\\ \operatorname{det}\left\langle v_{i}, w_{j}\right\rangle_{i, j} & \text { if } k=l\end{cases}
$$

If $e_{1}, \ldots, e_{q}$ is an orthonormal basis of $z_{0}$, then the set

$$
\begin{equation*}
\left\{e_{i_{1}} \wedge \cdots \wedge e_{i_{k}} \mid 1 \leq k \leq q, i_{1}<i_{2}<\cdots<i_{k}\right\} \tag{3.51}
\end{equation*}
$$

is an orthonormal basis of $\bigwedge z_{0}$. We define the Berezin integral $\int^{B}$ to be the orthogonal projection onto the top dimensional component, that is the map

$$
\begin{align*}
\int^{B}: \bigwedge z_{0} & \longrightarrow \mathbb{R} \\
w & \longmapsto\left\langle w, e_{1} \wedge \cdots \wedge e_{q}\right\rangle \tag{3.52}
\end{align*}
$$

The Berezin integral can then be extended to

$$
\begin{align*}
\int^{B}: \Omega\left(P / K, P \times_{K} \wedge z_{0}\right) & \longrightarrow \Omega(P / K) \\
\omega \otimes s & \longmapsto \omega \int^{B} s \tag{3.53}
\end{align*}
$$

where $\int^{B} s$ in $C^{\infty}(P / K)$ is the composition of the section with the Berezinian in every fiber. Let $s_{1}, \ldots, s_{q}$ be a local orthonormal frame of $P \times_{K} z_{0}$. Then $s_{1} \wedge \cdots \wedge s_{q}$ is in $\Omega^{0}\left(P / K, \wedge^{q} P \times_{K} z_{0}\right)$ and defines a global section. Hence for $\alpha$ in $\Omega\left(P / K, P \times_{K} \wedge z_{0}\right)$ we have

$$
\begin{equation*}
\int^{B} \alpha=\left\langle\alpha, s_{1} \wedge \cdots \wedge s_{q}\right\rangle \tag{3.54}
\end{equation*}
$$

Finally, for every section $s$ in $\Omega^{0,1}$ we can define the contraction

$$
\begin{align*}
i(s): \Omega_{P}^{i, j} & \longrightarrow \Omega_{P}^{i, j-1} \\
\omega \otimes s_{1} \wedge \cdots \wedge s_{j} & \longmapsto \sum_{k=1}^{j}(-1)^{i+k-1}\left\langle s, s_{k}\right\rangle \omega \otimes s_{1} \wedge \cdots \wedge \widehat{s_{k}} \wedge \cdots \wedge s_{j} \tag{3.55}
\end{align*}
$$

and extended by linearity, where the symbol $\widehat{\bullet}$ means that we remove it from the product. Note that when $j$ is zero then $i(s)$ is defined to be zero. The contraction $i(s)$ defines a derivation on $\oplus \widetilde{\Omega}^{i, j}$ that satisfies

$$
\begin{equation*}
i(s)\left(\alpha \wedge \alpha^{\prime}\right)=(i(s) \alpha) \wedge \alpha^{\prime}+(-1)^{i+j} \alpha \wedge\left(i(s) \alpha^{\prime}\right) \tag{3.56}
\end{equation*}
$$

for $\alpha$ in $\widetilde{\Omega}^{i, j}$ and $\alpha^{\prime}$ in $\widetilde{\Omega}^{k, l}$.

### 3.6 Thom forms

We denote by $E$ the bundle $G(\mathbb{R})^{+} \times_{K} z_{0}$. On the fibers of the bundle we have the inner product given by $\left\langle w, w^{\prime}\right\rangle:=-Q\left(w, w^{\prime}\right)$. Let $v$ be arbitrary vector in $L$ and $\Gamma_{v}$ its stabilizer. Since the bundle is $G(\mathbb{R})^{+}$-equivariant we have a bundle

$$
\begin{equation*}
\Gamma_{v} \backslash E \longrightarrow \Gamma_{v} \backslash \mathbb{D}^{+} \tag{3.57}
\end{equation*}
$$

and let $\mathrm{D}\left(\Gamma_{v} \backslash E\right)$ be the closed disk bundle. If we have a closed $(q+i)$-form on $\Gamma_{v} \backslash E$ whose support is contained in $\mathrm{D}\left(\Gamma_{v} \backslash E\right)$, then it has compact support in the fiber and represents a class in $H^{q+i}\left(\Gamma_{v} \backslash E, \Gamma_{v} \backslash E-\mathrm{D}\left(\Gamma_{v} \backslash E\right)\right)$. The cohomology group $H^{\bullet}\left(\Gamma_{v} \backslash E, \Gamma_{v} \backslash E-\mathrm{D}\left(\Gamma_{v} \backslash E\right)\right)$ is equal to the cohomology group $H^{\bullet}\left(\Gamma_{v} \backslash E, \Gamma_{v} \backslash\left(E-E_{0}\right)\right)$ that we used in the introduction, where $E_{0}$ is the zero section. Fiber integration induces an isomorphism on the level of cohomology

$$
\text { Th: } \begin{align*}
H^{q+i}\left(\Gamma_{v} \backslash E, \Gamma_{v} \backslash E-\mathrm{D}\left(\Gamma_{v} \backslash E\right)\right) & \longrightarrow H^{i}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right) \\
{[\omega] } & \longmapsto \int_{\text {fiber }} \omega \tag{3.58}
\end{align*}
$$

known as the Thom isomorphism [2, Theorem. 6.17]. When $i$ is zero then $H^{i}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right)$is $\mathbb{R}$ and we call the preimage of 1

$$
\begin{equation*}
\operatorname{Th}\left(\Gamma_{v} \backslash E\right):=\operatorname{Th}^{-1}(1) \in H^{q}\left(\Gamma_{v} \backslash E, \Gamma_{v} \backslash E-\mathrm{D}\left(\Gamma_{v} \backslash E\right)\right) \tag{3.59}
\end{equation*}
$$

the Thom class. Any differential form representating this class is called a Thom form, in particular every closed $q$-form on $\Gamma_{v} \backslash E$ that has compact support in every fiber and whose integral along every fiber is 1 is a Thom form. One can also view the Thom class as the Poincaré dual class of the zero section $E_{0}$ in $E$, in the same sense as for (2.24).

Let $\omega$ in $\Omega^{j}(E)$ be a form on the bundle and let $\omega_{z}$ be its restriction to a fiber $E_{z}=\pi^{-1}(z)$ for some $z$ in $\mathbb{D}^{+}$. After identifying $z_{0}$ with $\mathbb{R}^{q}$ we see $\omega_{z}$ as an element of $C^{\infty}\left(\mathbb{R}^{q}\right) \otimes \wedge^{j}\left(\mathbb{R}^{q}\right)^{*}$. We say that $\omega$ is rapidly decreasing in the fiber if $\omega_{z}$ lies in $\mathscr{S}\left(\mathbb{R}^{q}\right) \otimes \wedge^{j}\left(\mathbb{R}^{q}\right)^{*}$ for every $z$ in $\mathbb{D}^{+}$. We write $\Omega_{\text {rd }}^{j}(E)$ for the space of such forms.

Let $\Omega_{\mathrm{rd}}^{\bullet}\left(\Gamma_{v} \backslash E\right)$ be the complex of rapidly decreasing forms in the fiber. It is isomorphic to the complex $\Omega_{\mathrm{rd}}^{\bullet}(E)^{\Gamma_{v}}$ of rapidly decreasing $\Gamma_{v}$-invariant forms on $E$. Let $H_{\mathrm{rd}}\left(\Gamma_{v} \backslash E\right)$ the cohomology of this complex. The map

$$
\begin{align*}
h: \Gamma_{v} \backslash E & \longrightarrow \Gamma_{v} \backslash E \\
w & \longrightarrow \frac{w}{\sqrt{1-\|w\|^{2}}} \tag{3.60}
\end{align*}
$$

is a diffeomorphism from the open disk bundle $\mathrm{D}\left(\Gamma_{v} \backslash E\right)^{\circ}$ onto $\Gamma_{v} \backslash E$. It induces an isomorphism by pullback

$$
\begin{equation*}
h^{*}: H_{\mathrm{rd}}\left(\Gamma_{v} \backslash E\right) \longrightarrow H\left(\Gamma_{v} \backslash E, \Gamma_{v} \backslash E-\mathrm{D}\left(\Gamma_{v} \backslash E\right)\right), \tag{3.61}
\end{equation*}
$$

which commutes with the fiber integration. Hence we have the following version of the Thom isomorphism

$$
\begin{equation*}
H_{\mathrm{rd}}^{q+i}\left(\Gamma_{v} \backslash E\right) \longrightarrow H^{i}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right) \tag{3.62}
\end{equation*}
$$

The construction of Mathai and Quillen produces a Thom form

$$
\begin{equation*}
U_{M Q} \in \Omega_{\mathrm{rd}}^{q}(E) \tag{3.63}
\end{equation*}
$$

which is $G(\mathbb{R})^{+}$-invariant (hence $\Gamma_{v}$-invariant) and closed. We will recall their construction in the next section.

### 3.7 The Mathai-Quillen construction

As earlier let $\tilde{E}$ be the bundle $\left(G(\mathbb{R})^{+} \times z_{0}\right) \times_{K} z_{0}$. Let $\wedge^{j} \tilde{E}$ be the bundle $\left(G(\mathbb{R})^{+} \times z_{0}\right) \times_{K} \wedge^{j} z_{0}$ and

$$
\begin{align*}
& \Omega^{i, j}:=\Omega^{i}\left(\mathbb{D}^{+}, \wedge^{j} E\right) \\
& \widetilde{\Omega}^{i, j}:=\Omega^{i}\left(E, \wedge^{j} \widetilde{E}\right) \tag{3.64}
\end{align*}
$$

First consider the tautological section $\mathbf{s}$ of $E$ defined by

$$
\begin{equation*}
\mathbf{s}[g, w]:=[(g, w), w] \in \widetilde{E} \tag{3.65}
\end{equation*}
$$

This gives a canonical element $\mathbf{s}$ of $\widetilde{\Omega}^{0,1}$. Composing with the norm induced from the inner product we get an element $\|\mathbf{s}\|^{2}$ in $\widetilde{\Omega}^{0,0}$.

The representation $\rho$ on $z_{0}$ induces a representation on $\wedge^{i} z_{0}$ that we also denote by $\rho$. The derivative at the identity gives a map

$$
\begin{equation*}
\rho: \mathfrak{k} \longrightarrow \mathfrak{s o}\left(\wedge^{i} z_{0}\right) \tag{3.66}
\end{equation*}
$$

The connection form $\rho(\widetilde{\theta})$ in $\Omega^{1}\left(G(\mathbb{R})^{+} \times z_{0}, \wedge^{j} z_{0}\right)$ defines a covariant derivative

$$
\begin{equation*}
\widetilde{\nabla}: \widetilde{\Omega}^{0, j} \longrightarrow \widetilde{\Omega}^{1, j} \tag{3.67}
\end{equation*}
$$

on $\wedge^{j} \widetilde{E}$. We can extend it to a map

$$
\begin{equation*}
\widetilde{\nabla}: \widetilde{\Omega}^{i, j} \longrightarrow \widetilde{\Omega}^{i+1, j} \tag{3.68}
\end{equation*}
$$

by setting

$$
\begin{equation*}
\widetilde{\nabla}(\omega \otimes s):=d \omega \otimes s+(-1)^{i} \omega \wedge \widetilde{\nabla}(s) \tag{3.69}
\end{equation*}
$$

as in (3.30). The connection on $\widetilde{\Omega}^{i, j}$ is compatible with the metric. Finally, the covariant derivative $\widetilde{\nabla}$ defines a derivation on $\oplus \widetilde{\Omega}^{i, j}$ that satisfies

$$
\begin{equation*}
\widetilde{\nabla}\left(\alpha \wedge \alpha^{\prime}\right)=(\widetilde{\nabla} \alpha) \wedge \alpha^{\prime}+(-1)^{i+j} \alpha \wedge\left(\widetilde{\nabla} \alpha^{\prime}\right) \tag{3.70}
\end{equation*}
$$

for any $\alpha$ in $\widetilde{\Omega}^{i, j}$ and $\alpha^{\prime}$ in $\widetilde{\Omega}^{k, l}$.
Taking the derivative of the tautological section gives an element

$$
\begin{equation*}
\widetilde{\nabla} \mathbf{s}=d \mathbf{s}+\rho(\widetilde{\theta}) \mathbf{s} \in \widetilde{\Omega}^{1,1} \tag{3.71}
\end{equation*}
$$

Let $\mathfrak{s o}(\widetilde{E})$ denote the bundle $\left(G(\mathbb{R})^{+} \times z_{0}\right) \times_{K} \mathfrak{s o}\left(z_{0}\right)$ and consider the curvature $\rho(\widetilde{R})$ in $\Omega^{2}(\widetilde{E}, \mathfrak{s o}(\widetilde{E}))$. We have an isomorphism

$$
\begin{align*}
\left.T^{-1}\right|_{z_{0}}: \mathfrak{s o}\left(z_{0}\right) & \longrightarrow \wedge^{2} z_{0} \\
A & \longmapsto \sum_{i<j}\left\langle A e_{i}, e_{j}\right\rangle e_{i} \wedge e_{j} \tag{3.72}
\end{align*}
$$

The inverse sends $v \wedge w$ to the endomorphism $u \mapsto\langle v, u\rangle w-\langle w, u\rangle v$, and is the isomorphism from (2.11) restricted to $z_{0}$. Note that we have

$$
\begin{equation*}
T(v \wedge w) u=\iota(u) v \wedge w \tag{3.73}
\end{equation*}
$$

Using this isomorphism we can also identify $\mathfrak{s o}(\widetilde{E})$ and $\wedge^{2} \widetilde{E}$ so that we can view the curvature as an element

$$
\begin{equation*}
\rho(\widetilde{R}) \in \widetilde{\Omega}^{2,2} \tag{3.74}
\end{equation*}
$$

LEMMA 3.4. The form $\omega:=2 \pi\|\mathbf{s}\|^{2}+2 \sqrt{\pi} \widetilde{\nabla} \mathbf{s}-\rho(\widetilde{R})$ lying in $\widetilde{\Omega}^{0,0} \oplus \widetilde{\Omega}^{1,1} \oplus \widetilde{\Omega}^{2,2}$ is annihilated by $\widetilde{\nabla}+2 \sqrt{\pi} i(\mathbf{s})$. Moreover

$$
\begin{equation*}
d \int^{B} \alpha=\int^{B} \tilde{\nabla} \alpha \tag{3.75}
\end{equation*}
$$

for every form $\alpha$ in $\widetilde{\Omega}^{i, j}$. Hence $\int^{B} \exp (-\omega)$ is a closed form.

Proof. We have

$$
\begin{align*}
& (\widetilde{\nabla}+2 \sqrt{\pi} i(\mathbf{s}))\left(2 \pi\|\mathbf{s}\|^{2}+2 \sqrt{\pi} \widetilde{\nabla} \mathbf{s}-\rho(\widetilde{R})\right)  \tag{3.76}\\
& =2 \pi \widetilde{\nabla}\|\mathbf{s}\|^{2}+4 \pi^{\frac{3}{2}} i(\mathbf{s})\|\mathbf{s}\|^{2}+2 \sqrt{\pi} \widetilde{\nabla}^{2} \mathbf{s}+4 \pi i(x) \widetilde{\nabla} \mathbf{s}-\widetilde{\nabla} \rho(\widetilde{R})-2 \sqrt{\pi} i(\mathbf{s}) \rho(\widetilde{R})
\end{align*}
$$

It vanishes because we have the following:

- $i(\mathbf{s})\|\mathbf{s}\|^{2}=0$ since $\|\mathbf{s}\|$ is in $\widetilde{\Omega}^{0,0}$,
- $\widetilde{\nabla} \rho(\widetilde{R})=0$ by Bianchi's identity,
- $\widetilde{\nabla}\|\mathbf{s}\|^{2}=2\langle\widetilde{\nabla} \mathbf{s}, \mathbf{s}\rangle=-2 i(\mathbf{s}) \widetilde{\nabla} \mathbf{s}$,
- $\widetilde{\nabla}^{2} \mathbf{s}=\rho(\widetilde{R}) \mathbf{s}=i(\mathbf{s}) \rho(\widetilde{R})$.

For the last point we used (3.73) where we view $\rho(\widetilde{R})$ as an element of $\Omega^{2}(E, \mathfrak{s o}(\widetilde{E}))$, respectively of $\Omega^{2}\left(E, \wedge^{2} \widetilde{E}\right)$.

Let $s_{1} \wedge \cdots \wedge s_{q}$ in $\Omega^{0}\left(E, \wedge^{q} \widetilde{E}\right)$ be a global section where $s_{1}, \ldots, s_{q}$ is a local orthonormal frame for $\widetilde{E}$. Then for any $\alpha$ in $\widetilde{\Omega}^{i, j}$ we have

$$
\begin{equation*}
\int^{B} \alpha=\left\langle\alpha, s_{1} \wedge \cdots \wedge s_{q}\right\rangle \tag{3.77}
\end{equation*}
$$

This vanishes if $j$ is different from $q$, hence we can assume $\alpha$ is in $\widetilde{\Omega}^{i, q}$. If we write $\alpha$ as $\beta s_{1} \wedge \cdots \wedge s_{q}$ for some $\beta$ in $\Omega^{i}(E)$ then

$$
\begin{equation*}
\int^{B} \alpha=\beta . \tag{3.78}
\end{equation*}
$$

On the other hand, since the connection on $\widetilde{\Omega}^{i, q}$ is compatible with the metric, we have

$$
\begin{equation*}
0=d\left\langle s_{1} \wedge \cdots \wedge s_{q}, s_{1} \wedge \cdots \wedge s_{q}\right\rangle=2\left\langle\widetilde{\nabla}\left(s_{1} \wedge \cdots \wedge s_{q}\right), s_{1} \wedge \cdots \wedge s_{q}\right\rangle \tag{3.79}
\end{equation*}
$$

Then we have

$$
\begin{align*}
\int^{B} \widetilde{\nabla} \alpha & =\left\langle\widetilde{\nabla} \alpha, s_{1} \wedge \cdots \wedge s_{q}\right\rangle \\
& =\left\langle d \beta \otimes s_{1} \wedge \cdots \wedge s_{q}+(-1)^{i} \beta \wedge \widetilde{\nabla}\left(s_{1} \wedge \cdots \wedge s_{q}\right), s_{1} \wedge \cdots \wedge s_{q}\right\rangle \\
& =d \beta \\
& =d \int^{B} \alpha \tag{3.80}
\end{align*}
$$

Since $\widetilde{\nabla}+2 \sqrt{\pi} i(\mathbf{s})$ is a derivation that annihilates $\omega$ we have

$$
\begin{equation*}
(\widetilde{\nabla}+2 \sqrt{\pi} i(\mathbf{s})) \omega^{k}=0 \tag{3.81}
\end{equation*}
$$

for positive $k$. Hence it follows that

$$
\begin{align*}
d \int^{B} \exp (-\omega) & =\int^{B} \widetilde{\nabla} \exp (-\omega) \\
& =\int^{B}(\widetilde{\nabla}+2 \sqrt{\pi} i(\mathbf{s})) \exp (-\omega) \\
& =0 \tag{3.82}
\end{align*}
$$

In [9] Mathai and Quillen define the following form

$$
\begin{equation*}
U_{M Q}:=(-1)^{\frac{q(q+1)}{2}}(2 \pi)^{-\frac{q}{2}} \int^{B} \exp \left(-2 \pi\|\mathbf{s}\|^{2}-2 \sqrt{\pi} \widetilde{\nabla} \mathbf{s}+\rho(\widetilde{R})\right) \in \Omega_{r d}^{q}(E) \tag{3.83}
\end{equation*}
$$

We call it the Mathai-Quillen form.

Proposition 3.5. The Mathai-Quillen form is a Thom form.

Proof. From the previous lemma it follows that the form is closed. It remains to show that its integral along the fibers is 1 . The restriction of the form $U_{M Q}$ along the fiber $\pi^{-1}(e K)$ is given by

$$
\begin{align*}
U_{M Q} & =(-1)^{\frac{q(q+1)}{2}}(2 \pi)^{-\frac{q}{2}} e^{-2 \pi\|\mathbf{s}\|^{2}} \int^{B} \exp (-2 \sqrt{\pi} d \mathbf{s}) \\
& =(-1)^{\frac{q(q+1)}{2}} 2^{\frac{q}{2}} e^{-2 \pi\|\mathbf{s}\|^{2}}(-1)^{q} \int^{B}\left(d x_{1} \otimes e_{1}\right) \wedge \cdots \wedge\left(d x_{q} \otimes e_{q}\right) \\
& =2^{\frac{q}{2}} e^{-2 \pi\|\mathbf{s}\|^{2}} d x_{1} \wedge \cdots \wedge d x_{q} \tag{3.84}
\end{align*}
$$

and its integral over the fiber $\pi^{-1}(e K)$ is equal to 1 .

### 3.8 Transgression form

For $t>0$ consider the map $t: E \longrightarrow E$ given by multiplication by $t$ in the fibers. Consider the $K$-invariant vector field

$$
\begin{equation*}
X:=\sum_{i=1}^{q} x_{i} \frac{\partial}{\partial x_{i}} \tag{3.85}
\end{equation*}
$$

on $G(\mathbb{R})^{+} \times \mathbb{R}^{q}$. Since it is $K$-invariant it also induces a vector field on $E$. We define the transgression form $\psi$ in $\Omega^{q-1}(E)$ to be $\iota_{X} U_{M Q}$, where $\iota_{X}$ is the interior product.

Proposition 3.6 (Transgression formula). The transgression satisfies:

$$
\begin{equation*}
\left(\frac{d}{d t} t^{*} U_{M Q}\right)_{t=t_{0}}=-\frac{1}{t_{0}} d\left(t_{0}^{*} \psi\right) \tag{3.86}
\end{equation*}
$$

Proof. This is due to Mathai and Quillen. Let us view the multiplication map by $t$ as a map

$$
\begin{align*}
m: E \times \mathbb{R}_{>0} & \longrightarrow E \\
(e, t) & \longmapsto e t . \tag{3.87}
\end{align*}
$$

The differential $\tilde{d}$ on $E \times \mathbb{R}_{>0}$ splits as $d+d_{\mathbb{R}_{>0}}$. Since $U_{M Q}$ is closed (hence its pullback) we have

$$
\begin{equation*}
0=\tilde{d}\left(m^{*} U_{M Q}\right)=d\left(m^{*} U_{M Q}\right)+\frac{d}{d t}\left(m^{*} U_{M Q}\right) d t \tag{3.88}
\end{equation*}
$$

Moreover the pushforward of the vector field $t \frac{\partial}{\partial t}$ by $m$ is $X$, hence for the contraction we have

$$
\begin{equation*}
\iota_{\frac{\partial}{\partial t}} m^{*} U_{M Q}=\frac{1}{t} m^{*} \iota_{X} U_{M Q} \tag{3.89}
\end{equation*}
$$

Since the differential $d$ is independent of $t$ it commutes with the contraction $\iota_{\frac{\partial}{\partial t}}$. Combining with (3.88) yields

$$
\begin{equation*}
\frac{d}{d t}\left(m^{*} U_{M Q}\right)=-\frac{1}{t} d\left(m^{*} \psi\right) \tag{3.90}
\end{equation*}
$$

Finally, pulling back by the section

$$
\begin{array}{rl}
t_{0}: E & E \times \mathbb{R}_{>0} \\
e \longmapsto\left(e, t_{0}\right) \tag{3.91}
\end{array}
$$

gives the desired formula.
Let $\Gamma_{v}$ be the stabilizer of $v$ in $\Gamma$, which acts on the left on $E$. By the $G(\mathbb{R})^{+}$-invariance (hence $\Gamma_{v}$-invariance) of $U_{M Q}$, it is also a form in $\Omega^{q}\left(\Gamma_{v} \backslash E\right)$. Let $S_{0}$ denote the image $\Gamma_{v} \backslash E_{0}$ of the zero section in $\Gamma_{v} \backslash E$.

Proposition 3.7. The form $U_{M Q}$ represents the Poincaré dual of $S_{0}$ in $\Gamma_{v} \backslash E$.

Sketch of proof. For $0<t_{1}<t_{2}$ we have

$$
\begin{align*}
t_{2}^{*} U_{M Q}-t_{1}^{*} U_{M Q} & =\int_{t_{1}}^{t_{2}}\left(\frac{d}{d t} t^{*} U_{M Q}\right) d t \\
& =-\int_{t_{1}}^{t_{2}} d\left(t^{*} \psi\right) \frac{d t}{t} \\
& =-d \int_{t_{1}}^{t_{2}} t^{*} \psi \frac{d t}{t} \tag{3.92}
\end{align*}
$$

so that $t_{2}^{*} U_{M Q}$ and $t_{1}^{*} U_{M Q}$ represent the same cohomology class in $H^{q}\left(\Gamma_{v} \backslash E\right)$. Then, one can show that

$$
\begin{equation*}
\lim _{t \rightarrow \infty} t^{*} U_{M Q}=\delta_{S_{0}} \tag{3.93}
\end{equation*}
$$

where $\delta_{S_{0}}$ is the current of integration along $S_{0}$. Hence if $\omega$ is a form in $\Omega_{c}^{m}(E)$, where $m$ is the dimension of $\mathbb{D}^{+}$, then

$$
\begin{align*}
\int_{\Gamma_{v} \backslash E} U_{M Q} \wedge \omega & =\lim _{t \rightarrow \infty} \int_{\Gamma_{v} \backslash E} t^{*} U_{M Q} \wedge \omega \\
& =\int_{S_{0}} \omega \tag{3.94}
\end{align*}
$$

## 4 Computation of the Mathai-Quillen form

### 4.1 The section $s_{v}$

Let pr denote the orthogonal projection of $V(\mathbb{R})$ on the plane $z_{0}$. Consider the section

$$
\begin{align*}
s_{v}: \mathbb{D}^{+} & \longrightarrow E \\
z & \longmapsto\left[g_{z}, \operatorname{pr}\left(g_{z}^{-1} v\right)\right], \tag{4.1}
\end{align*}
$$

where $g_{z}$ is any element of $G(\mathbb{R})^{+}$sending $z_{0}$ to $z$. Let us denote by $L_{g}$ the left action of an element $g$ in $G(\mathbb{R})^{+}$on $\mathbb{D}^{+}$. We also denote by $L_{g}$ the action on $E$ given by $L_{g}\left[g_{z}, v\right]=\left[g g_{z}, v\right]$. The bundle is $G(\mathbb{R})^{+}$-equivariant with respect to these actions.

Proposition 4.1. The section $s_{v}$ is well-defined and $\Gamma_{v}$-equivariant. Moreover its zero locus is precisely $\mathbb{D}_{v}^{+}$.

Proof. The section is well-defined, since replacing $g_{z}$ by $g_{z} k$ gives

$$
\begin{equation*}
s_{v}(z)=\left[g_{z} k, \operatorname{pr}\left(k^{-1} g_{z}^{-1} v\right)\right]=\left[g_{z} k, k^{-1} \operatorname{pr}\left(g_{z}^{-1} v\right)\right]=\left[g, \operatorname{pr}\left(g_{z}^{-1} v\right)\right]=s_{v}(z) \tag{4.2}
\end{equation*}
$$

Suppose that $z$ is in the zero locus of $s_{v}$, that is to say $\operatorname{pr}\left(g_{z}^{-1} v\right)$ vanishes. Then $g_{z}^{-1} v$ is in $z_{0}^{\perp}$. It is equivalent to the fact that $z=g_{z} z_{0}$ is a subspace of $v^{\perp}$, which means that $z$ is in $\mathbb{D}_{v}^{+}$. Hence the zero locus of $s_{v}$ is exactly $\mathbb{D}_{v}^{+}$. For the equivariance, note that we have

$$
\begin{equation*}
s_{v} \circ L_{g}(z)=\left[g g_{z}, \operatorname{pr}\left(g_{z}^{-1} g^{-1} v\right)\right]=L_{g} \circ s_{g^{-1} v}(z) \tag{4.3}
\end{equation*}
$$

Hence if $\gamma$ is an element of $\Gamma_{v}$ we have

$$
\begin{equation*}
s_{v} \circ L_{\gamma}=L_{\gamma} \circ s_{v} \tag{4.4}
\end{equation*}
$$

We define the pullback $\varphi^{0}(v):=s_{v}^{*} U_{M Q}$ of the Mathai-Quillen form by $s_{v}$. It defines a form

$$
\begin{equation*}
\varphi^{0} \in C^{\infty}\left(\mathbb{R}^{p+q}\right) \otimes \Omega^{q}(\mathbb{D})^{+} \tag{4.5}
\end{equation*}
$$

It is only rapidly decrasing on $\mathbb{R}^{q}$, and in order to make it rapidly decreasing everywhere we set

$$
\begin{equation*}
\varphi(v):=e^{-\pi Q(v, v)} \varphi^{0}(v) \tag{4.6}
\end{equation*}
$$

It defines a form $\varphi \in \mathscr{S}\left(\mathbb{R}^{p+q}\right) \otimes \Omega^{q}(\mathbb{D})^{+}$

Proposition 4.2. 1. For fixed $v$ in $V(\mathbb{R})$ the form $\varphi^{0}(v)$ in $\Omega^{q}\left(\mathbb{D}^{+}\right)$is given by

$$
\begin{equation*}
\varphi^{0}(v)=(-1)^{\frac{q(q+1)}{2}}(2 \pi)^{-\frac{q}{2}} \exp \left(\left.2 \pi Q\right|_{z_{0}}(v, v)\right) \int^{B} \exp \left(-2 \sqrt{\pi} \nabla s_{v}+\rho(R)\right) \tag{4.7}
\end{equation*}
$$

2. It satisfies $L_{g}^{*} \varphi^{0}(v)=\varphi^{0}\left(g^{-1} v\right)$, hence

$$
\begin{equation*}
\varphi^{0} \in\left[\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes C^{\infty}\left(\mathbb{R}^{p+q}\right)\right]^{G(\mathbb{R})^{+}} \tag{4.8}
\end{equation*}
$$

3. It is a Poincaré dual of $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$in $\Gamma_{v} \backslash \mathbb{D}^{+}$.

Proof. 1. Recall that $\widetilde{\nabla}=\pi^{*} \nabla$ and $\widetilde{R}=\pi^{*} R$. We pullback by $s_{v}$

Since $\pi \circ s_{v}$ is the identity we have

$$
\begin{equation*}
s_{v}^{*} \widetilde{\nabla}=s_{v}^{*} \pi^{*} \nabla=\nabla \tag{4.9}
\end{equation*}
$$

Hence, the pullback connection $s_{v}^{*} \widetilde{\nabla}$ satisfies

$$
\begin{equation*}
s_{v}^{*}(\widetilde{\nabla} \mathbf{s})=\left(s_{v}^{*} \widetilde{\nabla}\right)\left(s_{v}^{*} \mathbf{s}\right)=\nabla s_{v} \tag{4.10}
\end{equation*}
$$

since $s_{v}^{*} \mathbf{s}=s_{v}$. We also have $s_{v}^{*} \widetilde{R}=R$ and

$$
\begin{equation*}
s_{v}^{*}\|\mathbf{s}\|^{2}=\left\|s_{v}\right\|^{2}=\left\langle s_{v}, s_{v}\right\rangle=-\left.Q\right|_{z_{0}}(v, v) . \tag{4.11}
\end{equation*}
$$

The expression for $\varphi^{0}$ then follows from the fact that $\exp$ and $s_{v}^{*}$ commute.
2. The bundle $E$ is $G(\mathbb{R})^{+}$equivariant. By construction the Mathai-Quillen is $G(\mathbb{R})^{+}$-invariant, so $L_{g}^{*} U_{M Q}=U_{M Q}$. On the other hand we also have

$$
\begin{equation*}
s_{v} \circ L_{g}(z)=L_{g} \circ s_{g^{-1} v}(z) \tag{4.12}
\end{equation*}
$$

and thus

$$
\begin{equation*}
L_{g}^{*} \varphi^{0}(v)=L_{g}^{*} s_{v}^{*} U_{M Q}=\varphi^{0}\left(g^{-1} v\right) \tag{4.13}
\end{equation*}
$$

3. Since $s_{v}$ is $\Gamma_{v}$-equivariant we view it as a section

$$
\begin{equation*}
s_{v}: \Gamma_{v} \backslash \mathbb{D}^{+} \longrightarrow \Gamma_{v} \backslash E, \tag{4.14}
\end{equation*}
$$

whose zero locus is precisely $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$. Let $S_{0}$ (respectively $S_{v}$ ) be the image in $\Gamma_{v} \backslash E$ of the section $s_{v}$ (respectively the zero section). By Proposition 3.7 the Thom form $U_{M Q}$ is a Poincaré dual of
$S_{0}$. For a form $\omega$ in $\Omega_{c}^{m-q}\left(\Gamma_{v} \backslash \mathbb{D}^{+}\right)$we have

$$
\begin{align*}
\int_{\Gamma_{v} \backslash \mathbb{D}^{+}} \varphi^{0}(v) \wedge \omega & =\int_{\Gamma_{v} \backslash \mathbb{D}^{+}} s_{v}^{*}\left(U_{M Q} \wedge \pi^{*} \omega\right) \\
& =\int_{S_{v}} U_{M Q} \wedge \pi^{*} \omega \\
& =\int_{S_{v} \cap S_{0}} \pi^{*} \omega \\
& =\int_{\Gamma_{v} \backslash \mathbb{D}_{v}^{+}} \omega \tag{4.15}
\end{align*}
$$

The last step follows from the fact $\pi^{-1}\left(S_{v} \cap S_{0}\right)$ equals $\Gamma_{v} \backslash \mathbb{D}_{v}^{+}$.

As in (2.19) we have an isomorphism

$$
\begin{equation*}
\left[\Omega^{q}\left(\mathbb{D}^{+}\right) \otimes C^{\infty}\left(\mathbb{R}^{p+q}\right)\right]^{G(\mathbb{R})^{+}} \longrightarrow\left[\bigwedge^{q} \mathfrak{p}^{*} \otimes C^{\infty}\left(\mathbb{R}^{p+q}\right)\right]^{K} \tag{4.16}
\end{equation*}
$$

by evaluating at the basepoint $e K$ of $G(\mathbb{R})^{+} / K$ that corresponds to $z_{0}$ in $\mathbb{D}^{+}$. We will now compute $\left.\varphi^{0}\right|_{e K}$.

### 4.2 The Mathai-Quillen form at the identity

From now on we identify $\mathbb{R}^{p+q}$ with $V(\mathbb{R})$ by the orthonormal basis of (2.1), and let $z_{0}$ be the negative spanned by the vectors $e_{p+1}, \cdots, e_{p+q}$. Hence we identify $z_{0}$ with $\mathbb{R}^{q}$ and the quadratic form is

$$
\begin{equation*}
\left.Q\right|_{z_{0}}(v, v)=-\sum_{\mu=p+1}^{p+q} x_{\mu}^{2} \tag{4.17}
\end{equation*}
$$

where $x_{p+1}, \ldots, x_{p+q}$ are the coordinates of the vector $v$.
Let $f_{v}$ in $\Omega^{0}\left(G(\mathbb{R})^{+}, z_{0}\right)^{K}$ be the map associated to the section $s_{v}$, as in Proposition 3.1. It is defined by

$$
\begin{equation*}
f_{v}(g)=\operatorname{pr}\left(g^{-1} v\right) \tag{4.18}
\end{equation*}
$$

Then $d f_{v}+\rho(\theta) f_{v}$ is the horizontal lift of $\nabla s_{v}$, as discussed in Section 3.1. Let $X$ be a vector in $\mathfrak{g}$ and let $X_{\mathfrak{p}}$ and $X_{\mathfrak{k}}$ be its components with respect to the splitting of $\mathfrak{g}$ as $\mathfrak{p} \oplus \mathfrak{k}$. We have

$$
\begin{equation*}
\left(d f_{v}+\rho(\theta) f_{v}\right)_{e}(X)=d_{e} f_{v}\left(X_{\mathfrak{p}}\right) \tag{4.19}
\end{equation*}
$$

In particular we can evaluate on the basis $X_{\alpha \mu}$ and get:

$$
\begin{align*}
d_{e} f_{v}\left(X_{\alpha \mu}\right) & =\left.\frac{d}{d t}\right|_{t=0} f_{v}\left(\exp t X_{\alpha \mu}\right) \\
& =-\operatorname{pr}\left(X_{\alpha \mu} v\right) \\
& =-\operatorname{pr}\left(x_{\mu} e_{\alpha}+x_{\alpha} e_{\mu}\right) \\
& =-x_{\alpha} e_{\mu} \tag{4.20}
\end{align*}
$$

So as an element of $\mathfrak{p}^{*} \otimes z_{0}$ we can write

$$
\begin{equation*}
d_{e} f_{v}=-\sum_{\mu=p+1}^{p+q}\left(\sum_{\alpha=1}^{p} x_{\alpha} \omega_{\alpha \mu}\right) \otimes e_{\mu}=-\sum_{\alpha=1}^{p} x_{\alpha} \eta_{\alpha}, \tag{4.21}
\end{equation*}
$$

with

$$
\begin{equation*}
\eta_{\alpha}:=\sum_{\mu=p+1}^{p+q} \omega_{\alpha \mu} \otimes e_{\mu} \in \Omega^{1,1} \tag{4.22}
\end{equation*}
$$

Proposition 4.3. Let $\rho\left(R_{e}\right)$ in $\wedge^{2} \mathfrak{p}^{*} \otimes \mathfrak{s o}\left(z_{0}\right)$ be the curvature at the identity. Then after identifying $\mathfrak{s o}\left(z_{0}\right)$ with $\wedge^{2} z_{0}$ we have

$$
\begin{equation*}
\rho\left(R_{e}\right)=-\frac{1}{2} \sum_{\alpha=1}^{p} \eta_{\alpha}^{2} \in \wedge^{2} \mathfrak{p}^{*} \otimes \wedge^{2} z_{0} \tag{4.23}
\end{equation*}
$$

where $\eta_{\alpha}^{2}=\eta_{\alpha} \wedge \eta_{\alpha}$.

Proof. Using the relation $E_{i j} E_{k l}=\delta_{i l} E_{k j}$ one can show that

$$
\begin{equation*}
\left[X_{\alpha \mu}, X_{\beta \nu}\right]=\delta_{\mu \nu} X_{\alpha \beta}+\delta_{\alpha \beta} X_{\mu \nu} \tag{4.24}
\end{equation*}
$$

for two vectors $X_{\alpha \nu}$ and $X_{\beta \mu}$ in $\mathfrak{p}$. Hence we have

$$
\begin{align*}
R_{e}\left(X_{\alpha \nu} \wedge X_{\beta \mu}\right) & =\left[\theta\left(X_{\alpha \nu}\right), \theta\left(X_{\beta \mu}\right)\right]-\theta\left(\left[X_{\alpha \nu}, X_{\beta \mu}\right]\right) \\
& =-\theta\left(\left[X_{\alpha \nu}, X_{\beta \mu}\right]\right) \\
& =-p\left(\delta_{\alpha \beta} X_{\nu \mu}+\delta_{\nu \mu} X_{\alpha \beta}\right) \\
& =-\delta_{\alpha \beta} X_{\nu \mu} . \tag{4.25}
\end{align*}
$$

On the other hand, since $\eta_{i}\left(X_{j r}\right)=\delta_{i j} e_{r}$, we also have

$$
\begin{align*}
\sum_{i=1}^{p} \eta_{i}^{2}\left(X_{\alpha \nu} \wedge X_{\beta \mu}\right) & =\sum_{i=1}^{p} \eta_{i}\left(X_{\alpha \nu}\right) \wedge \eta_{i}\left(X_{\beta \mu}\right)-\eta_{i}\left(X_{\beta \mu}\right) \wedge \eta_{i}\left(X_{\alpha \nu}\right) \\
& =2 \delta_{\alpha \beta} e_{\nu} \wedge e_{\mu} \tag{4.26}
\end{align*}
$$

The lemma follows since $\rho\left(X_{\nu \mu}\right)=T\left(e_{\nu} \wedge e_{\mu}\right)$ in $\mathfrak{s o}\left(z_{0}\right)$, because

$$
\begin{equation*}
Q\left(\rho\left(X_{\nu \mu}\right) e_{\nu}, e_{\mu}\right) e_{\nu} \wedge e_{\mu}=-Q\left(e_{\mu}, e_{\mu}\right) e_{\nu} \wedge e_{\mu}=e_{\nu} \wedge e_{\mu} \tag{4.27}
\end{equation*}
$$

Using the fact that the exponential satisfies $\exp (\omega+\eta)=\exp (\omega) \exp (\eta)$ on the subalgebra $\bigoplus \Omega^{i, i}$ - see Remark 3.1 - we can write

$$
\begin{equation*}
\left.\varphi^{0}\right|_{e}(v)=(-1)^{\frac{q(q+1)}{2}}(2 \pi)^{-\frac{q}{2}} \exp \left(\left.2 \pi Q\right|_{z_{0}}(v, v)\right) \int^{B} \prod_{\alpha=1}^{p} \exp \left(2 \sqrt{\pi} x_{\alpha} \eta_{\alpha}-\frac{1}{2} \eta_{\alpha}^{2}\right) \tag{4.28}
\end{equation*}
$$

We define the $n$-th Hermite polynomial by

$$
\begin{equation*}
H_{n}(x):=\left(2 x-\frac{d}{d x}\right) \cdot 1 \in \mathbb{R}[x] \tag{4.29}
\end{equation*}
$$

The first three Hermite polynomials are $H_{0}(x)=1, H_{1}(x)=2 x$ and $H_{2}(x)=4 x^{2}-2$.

LEMMA 4.4. Let $\eta$ be a form in $\bigoplus \Omega^{i, i}$. Then

$$
\begin{equation*}
\exp \left(2 x \eta-\eta^{2}\right)=\sum_{n \geq 0} \frac{1}{n!} H_{n}(x) \eta^{n} \tag{4.30}
\end{equation*}
$$

where $H_{n}$ is the $n$-th Hermite polynomial.

Proof. Since $\eta$ and $\eta^{2}$ are in $\bigoplus \Omega^{i, i}$, they commute and we can use the binomial formula:

$$
\begin{align*}
\exp \left(2 x \eta-\eta^{2}\right) & =\sum_{k \geq 0} \frac{1}{k!}\left(2 x \eta-\eta^{2}\right)^{k} \\
& =\sum_{k \geq 0} \frac{1}{k!} \sum_{l=0}^{k}\binom{k}{l}(2 x \eta)^{k-l}\left(-\eta^{2}\right)^{l} \\
& =\sum_{k \geq 0} \frac{1}{k!} \sum_{l=0}^{k}\binom{k}{l}(2 x)^{k-l}(-1)^{l} \eta^{l+k} \\
& =\sum_{n \geq 0} P_{n}(x) \eta^{n} \tag{4.31}
\end{align*}
$$

where

$$
\begin{equation*}
P_{n}(x):=\sum_{\substack{0 \leq l \leq k \leq n \\ k+l=n}} \frac{(-1)^{l}}{l!(k-l)!}(2 x)^{k-l} \tag{4.32}
\end{equation*}
$$

The conditions on $k$ and $l$ imply that $n$ is less than or equal to $2 k$. First suppose that $n$ is even. Then we have that $k$ is between $\frac{n}{2}$ and $n$, so that the sum above can be written

$$
\begin{equation*}
\sum_{k=\frac{n}{2}}^{n} \frac{(-1)^{n-k}}{(n-k)!(2 k-n)!}(2 x)^{2 k-n}=\sum_{m=0}^{\frac{n}{2}} \frac{(-1)^{\frac{n}{2}-m}}{\left(\frac{n}{2}-m\right)!(2 m)!}(2 x)^{2 m}=\frac{1}{n!} H_{n}(x) \tag{4.33}
\end{equation*}
$$

where in the second step we let $m$ be $k-\frac{n}{2}$. If $n$ is odd then $k$ is between $\frac{n+1}{2}$ and $n$, so that the sum can be written

$$
\begin{equation*}
\sum_{k=\frac{n+1}{2}}^{n} \frac{(-1)^{n-k}}{(n-k)!(2 k-n)!}(2 x)^{2 k-n}=\sum_{m=0}^{\frac{n-1}{2}} \frac{(-1)^{\frac{n-1}{2}-m}}{\left(\frac{n-1}{2}-m\right)!(2 m+1)!}(2 x)^{2 m+1}=\frac{1}{n!} H_{n}(x) . \tag{4.34}
\end{equation*}
$$

Applying the lemma to (4.28) we get

$$
\begin{align*}
& \int^{B} \prod_{\alpha=1}^{p} \exp \left(2 \sqrt{\pi} x_{\alpha} \eta_{\alpha}-\frac{1}{2} \eta_{\alpha}^{2}\right) \\
& =\int^{B} \prod_{\alpha=1}^{p} \exp \left(2 \sqrt{2 \pi} x_{\alpha} \frac{\eta_{\alpha}}{\sqrt{2}}-\left(\frac{\eta_{\alpha}}{\sqrt{2}}\right)^{2}\right) \\
& =\int^{B} \prod_{\alpha=1}^{p} \sum_{n \geq 0} \frac{2^{-n / 2}}{n!} H_{n}\left(\sqrt{2 \pi} x_{\alpha}\right) \eta_{\alpha}^{n} \\
& =\sum_{n_{1}, \ldots, n_{p}} \frac{2^{-\frac{n_{1}+\cdots+n_{p}}{2}}}{n_{1}!\cdots n_{p}!} H_{n_{1}}\left(\sqrt{2 \pi} x_{1}\right) \cdots H_{n_{p}}\left(\sqrt{2 \pi} x_{p}\right) \int^{B} \eta_{1}^{n_{1}} \wedge \cdots \wedge \eta_{p}^{n_{p}} . \tag{4.35}
\end{align*}
$$

If $n_{1}+\cdots+n_{p}$ is different from $q$, then the Berezinian of $\eta_{1}^{n_{1}} \wedge \cdots \wedge \eta_{p}^{n_{p}}$ vanishes and we get

$$
\begin{align*}
& \sum_{n_{1}, \ldots, n_{p}} \frac{2^{-\frac{n_{1}+\cdots+n_{p}}{2}}}{n_{1}!\cdots n_{p}!} H_{n_{1}}\left(\sqrt{2 \pi} x_{1}\right) \cdots H_{n_{p}}\left(\sqrt{2 \pi} x_{p}\right) \int^{B} \eta_{1}^{n_{1}} \wedge \cdots \wedge \eta_{p}^{n_{p}} \\
= & 2^{-\frac{q}{2}} \sum_{n_{1}+\cdots+n_{p}=q} \frac{H_{n_{1}}\left(\sqrt{2 \pi} x_{1}\right) \cdots H_{n_{p}}\left(\sqrt{2 \pi} x_{p}\right)}{n_{1}!\cdots n_{p}!} \int^{B} \eta_{1}^{n_{1}} \wedge \cdots \wedge \eta_{p}^{n_{p}} . \tag{4.36}
\end{align*}
$$

Note that

$$
\begin{align*}
\eta_{\alpha}^{n_{\alpha}} & =\left(\sum_{\mu=p+1}^{p+q} \omega_{\alpha \mu} \otimes e_{\mu}\right)^{n_{\alpha}} \\
& =\sum_{\mu_{1}, \ldots, \mu_{n_{\alpha}}}\left(\omega_{\alpha \mu_{1}} \otimes e_{\mu_{1}}\right) \wedge \cdots \wedge\left(\omega_{\alpha \mu_{n_{\alpha}}} \otimes e_{\mu_{n_{\alpha}}}\right) \\
& =n_{\alpha}!\sum_{\mu_{1}<\cdots<\mu_{n_{\alpha}}}\left(\omega_{\alpha \mu_{1}} \otimes e_{\mu_{1}}\right) \wedge \cdots \wedge\left(\omega_{\alpha \mu_{n_{\alpha}}} \otimes e_{\mu_{n_{\alpha}}}\right), \tag{4.37}
\end{align*}
$$

where the sums are over all $\mu_{i}$ 's between $p+1$ and $p+q$. If $n_{1}+\cdots+n_{p}$ is equal to $q$ we have

$$
\begin{align*}
& \int^{B} \eta_{1}^{n_{1}} \wedge \cdots \wedge \eta_{p}^{n_{p}} \\
& =\int^{B} \prod_{\alpha=1}^{p}\left(\sum_{\mu=p+1}^{p+q} \omega_{\alpha \mu} \otimes e_{\mu}\right)^{n_{\alpha}} \\
& =\int^{B} \prod_{\alpha=1}^{p} n_{\alpha}!\sum_{\mu_{1}<\cdots<\mu_{n_{\alpha}}}\left(\omega_{\alpha \mu_{1}} \otimes e_{\mu_{1}}\right) \wedge \cdots \wedge\left(\omega_{\alpha \mu_{n_{\alpha}}} \otimes e_{\mu_{n_{\alpha}}}\right) \\
& =n_{1}!\cdots n_{p}!\sum \int^{B}\left(\omega_{\alpha(p+1)} \otimes e_{1}\right) \wedge \cdots \wedge\left(\omega_{\alpha(p+q)} \otimes e_{q}\right) \\
& =(-1)^{\frac{q(q+1)}{2}} n_{1}!\cdots n_{p}!\sum \omega_{\alpha_{1}(p+1)} \wedge \cdots \wedge \omega_{\alpha_{q}(p+q)} \tag{4.38}
\end{align*}
$$

where the sums in the last two lines go over all tuples $\underline{\alpha}=\left(\alpha_{1}, \ldots, \alpha_{q}\right)$ with $\alpha$ between 1 and $p$, and
the value $\alpha$ appears exactly $n_{\alpha}$-times in $\underline{\alpha}$. Hence

$$
\begin{align*}
\left.\varphi^{0}\right|_{e}(v)=2^{-q} \pi^{-\frac{q}{2}} \sum \omega_{\alpha_{1}(p+1)} & \wedge \cdots \wedge \omega_{\alpha_{q}(p+q)} \otimes H_{n_{1}}\left(\sqrt{2 \pi} x_{1}\right)  \tag{4.39}\\
\cdots & H_{n_{p}}\left(\sqrt{2 \pi} x_{p}\right) \exp \left(\left.2 \pi Q\right|_{z_{0}}(v, v)\right)
\end{align*}
$$

After multiplying by $\exp (-\pi Q(v, v))$ we get

$$
\begin{align*}
\left.\varphi\right|_{e}(v)=2^{-q} \pi^{-\frac{q}{2}} \sum \omega_{\alpha_{1}(p+1)} & \wedge \cdots \wedge \omega_{\alpha_{q}(p+q)} \otimes H_{n_{1}}\left(\sqrt{2 \pi} x_{1}\right)  \tag{4.40}\\
\cdots & H_{n_{p}}\left(\sqrt{2 \pi} x_{p}\right) \exp \left(-\pi Q_{z_{0}}^{+}(v, v)\right)
\end{align*}
$$

The form is now rapidly decreasing in $v$, since the Siegel majorant is positive definite. We have

$$
\begin{equation*}
\left.\varphi\right|_{e} \in\left[\bigwedge^{q} \mathfrak{p}^{*} \otimes \mathscr{S}\left(\mathbb{R}^{p+q}\right)\right]^{K} \tag{4.41}
\end{equation*}
$$

THEOREM 4.5. We have $2^{-\frac{q}{2}} \varphi(v)=\varphi_{K M}(v)$.

Proof. It is a straightforward computation to show that

$$
\begin{equation*}
(2 \pi)^{-n_{\alpha} / 2} H_{n_{\alpha}}\left(\sqrt{2 \pi} x_{\alpha}\right) \exp \left(-\pi x_{\alpha}^{2}\right)=\left(x_{\alpha}-\frac{1}{2 \pi} \frac{\partial}{\partial x_{\alpha}}\right)^{n_{\alpha}} \exp \left(-\pi x_{\alpha}^{2}\right) \tag{4.42}
\end{equation*}
$$

Hence applying this we find that the Kudla-Millson form, defined by the Howe operators in (2.22), is

$$
\begin{align*}
\left.\varphi_{K M}\right|_{e}(v)= & 2^{-q}(2 \pi)^{-\frac{q}{2}} \sum \omega_{\alpha_{1}(p+1)} \wedge \cdots \wedge \omega_{\alpha_{q}(p+q)} \otimes H_{n_{1}}\left(\sqrt{2 \pi} x_{1}\right) \\
& \cdots H_{n_{p}}\left(\sqrt{2 \pi} x_{p}\right) \exp \left(-\left.\pi Q\right|_{z_{0}}(v, v)\right) \\
= & \left.2^{-\frac{q}{2}} e^{-\pi Q(v, v)} \varphi^{0}\right|_{e}(v) \tag{4.43}
\end{align*}
$$

## 5 Examples

1. Let us compute the Kudla-Millson as above in the simplest setting of signature $(1,1)$. Let $V(\mathbb{R})$ be the quadratic space $\mathbb{R}^{2}$ with the quadratic form $Q(v, w)=x^{\prime} y+x y^{\prime}$ where $x$ and $x^{\prime}$ (respectively $y$ and $y^{\prime}$ ) are the components of $v$ (respectively of $w$ ). Let $e_{1}=\frac{1}{\sqrt{2}}(1,1)$ and $e_{2}=\frac{1}{\sqrt{2}}(1,-1)$. The 1-dimensional negative plane $z_{0}$ is $\mathbb{R} e_{2}$. If $r$ denotes the variable on $z_{0}$ then the quadratic form is $\left.Q\right|_{z_{0}}(r)=-r^{2}$. The projection map is given by

$$
\begin{align*}
& \text { pr: } V(\mathbb{R}) \longrightarrow z_{0} \\
& v=\left(x, x^{\prime}\right) \longmapsto \frac{x-x^{\prime}}{\sqrt{2}} . \tag{5.1}
\end{align*}
$$

The orthogonal group of $V(\mathbb{R})$ is

$$
G(\mathbb{R})^{+}=\left\{\left(\begin{array}{cc}
t & 0  \tag{5.2}\\
0 & t^{-1}
\end{array}\right), t>0\right\}
$$

and $\mathbb{D}^{+}$can be identified with $\mathbb{R}_{>0}$. The associated bundle $E$ is $\mathbb{R}_{>0} \times \mathbb{R}$ and the connection $\nabla$ is simply $d$ since the bundle is trivial. Hence the Mathai-Quillen form is

$$
\begin{equation*}
U_{M Q}=\sqrt{2} e^{-2 \pi r^{2}} d r \in \Omega^{1}(E) \tag{5.3}
\end{equation*}
$$

as in the proof of Proposition 3.5. The section $s_{v}: \mathbb{R}_{>0} \rightarrow E$ is given by

$$
\begin{equation*}
s_{v}(t)=\left(t, \frac{t^{-1} x-t x^{\prime}}{\sqrt{2}}\right) \tag{5.4}
\end{equation*}
$$

where $x$ and $x^{\prime}$ are the components of $v$. We obtain

$$
\begin{equation*}
s_{v}^{*} U_{M Q}=e^{-\pi\left(\frac{x}{t}-t x^{\prime}\right)^{2}}\left(\frac{x}{t}+t x^{\prime}\right) \frac{d t}{t} . \tag{5.5}
\end{equation*}
$$

Hence after multiplication by $2^{-\frac{1}{2}} e^{-\pi Q(v, v)}$ we get

$$
\begin{equation*}
\varphi_{K M}\left(x, x^{\prime}\right)=2^{-\frac{1}{2}} e^{-\pi\left[\left(\frac{x}{t}\right)^{2}+\left(t x^{\prime}\right)^{2}\right]}\left(\frac{x}{t}+t x^{\prime}\right) \frac{d t}{t} \tag{5.6}
\end{equation*}
$$

2. The second example illustrates the functorial properties of the Mathai-Quillen form. Suppose that we have an orthogonal splitting of $V(\mathbb{R})$ as $\bigoplus_{i}^{r} V_{i}(\mathbb{R})$. Let $\left(p_{i}, q_{i}\right)$ be the signature of $V_{i}(\mathbb{R})$. We have

$$
\begin{equation*}
\mathbb{D}_{1} \times \cdots \times \mathbb{D}_{r} \simeq\left\{z \in \mathbb{D} \mid z=\bigoplus_{i=1}^{r} z \cap V_{i}(\mathbb{R})\right\} \tag{5.7}
\end{equation*}
$$

Suppose we fix $z_{0}=z_{0}^{1} \oplus \cdots \oplus z_{0}^{r}$ in $\mathbb{D}_{1}^{+} \times \cdots \times \mathbb{D}_{r}^{+} \subset \mathbb{D}$, where $z_{0}^{i}$ is a negative $q_{i}$-plane in $V_{i}(\mathbb{R})$. Let $G_{i}(\mathbb{R})$ be the subgroup preserving $V_{i}(\mathbb{R})$, let $K_{i}$ the stabilizer of $z_{0}^{i}$ and $\mathbb{D}_{i}$ be the symmetric space associated to $V_{i}(\mathbb{R})$.
Over $\mathbb{D}_{1}^{+} \times \cdots \times \mathbb{D}_{r}^{+}$the bundle $E$ splits as an orthogonal sum $E_{1} \oplus \cdots \oplus E_{r}$, where $E_{i}$ is the bundle $G_{i}(\mathbb{R})^{+} \times_{K_{i}} z_{0}^{i}$. Moreover the restriction of the Mathai-Quillen form to this subbundle is

$$
\begin{equation*}
\left.U_{M Q}\right|_{E_{1} \times \cdots \times E_{r}}=U_{M Q}^{1} \wedge \cdots \wedge U_{M Q}^{r} \tag{5.8}
\end{equation*}
$$

where $U_{M Q}^{i}$ is the Mathai-Quillen form on $E_{i}$. The section $s_{v}$ also splits as a direct sum $\oplus s_{v_{i}}$ where $v_{i}$ is the projection of $v$ onto $v_{i}$. In summary the following diagram commutes

$$
\begin{align*}
& E_{1} \oplus \cdots \oplus E_{r} \longleftrightarrow \\
& \quad \oplus s_{v_{i}} \uparrow  \tag{5.9}\\
& \mathbb{D}_{1}^{+} \times \cdots \times \mathbb{D}_{r}^{+} \longleftrightarrow \mathbb{D}^{+} \uparrow
\end{align*}
$$

and we can conclude that

$$
\begin{equation*}
\left.\varphi_{K M}(v)\right|_{\mathbb{D}_{1}^{+} \times \cdots \times \mathbb{D}_{r}^{+}}=\varphi_{K M}^{1}\left(v_{1}\right) \wedge \cdots \wedge \varphi_{K M}^{r}\left(v_{r}\right) \tag{5.10}
\end{equation*}
$$

where $\varphi_{K M}^{i}$ is the Kudla-Millson form on $\mathbb{D}_{i}^{+}$.
