

sis of how phonon-mediated electron-electron interactions affect these transport times has not been carried out in the literature of hydrodynamics in WSM.

Let us summarize our results. First of all, there is a characteristic temperature scale, the Bloch-Grüneisen temperature T_{BG} , delimiting two temperature regimes (we assume that the Debye temperature T_{D} is larger, as is the case for metals with small Fermi momenta p_f). Such temperature scale appears in models that only consider phonon emission/absorption [10, 12]. Above T_{BG} , virtual phonon effects are non-negligible when the phonon linewidth Γ is dominated by the effects of the phonon-electron interaction. In this regime electronic scattering times are equal to those of phonon emission and absorption as the virtual phonons act like on-shell real phonons, with quantum interference effects becoming negligible, but the Lorenz ratio acquires a constant value different from L_0 . When there are stronger decay channels for phonons than those provided by the interaction with electrons, then the effects of electron scattering in this temperature regime are suppressed and $L = L_0$.

For temperatures below T_{BG} , phonons no longer act on-shell as they are not thermally activated, and the quantum fermionic interference between different scattering channels becomes non-negligible. For a simple quadratic band model, this would lead to the effects of electron scattering by virtual phonons being suppressed with respect to the phonon emission/absorption and scattering off impurities. Fundamentally, the wavefunction overlaps associated with the scattering of the Weyl quasiparticles make the contribution of phonon-mediated electron scattering non-negligible. This results in $\tau_{\text{e-e}} \propto T^{-2}$ relaxation times, opening up a parameter window for which electron scattering can dominate thermoelectric transport for small temperatures for a strong electron-phonon coupling, thus enabling electron hydrodynamic behavior, which would otherwise be suppressed due to extra factors of $T/p_f \ll 1$.

II. THE MODEL

A. Particles

We consider the electron dynamics in a WSM described by the following two-band Hamiltonian [15, 16]

$$H_0 = \int_{\mathbf{p}} \psi_{\mathbf{p}}^{\dagger} [\boldsymbol{\sigma} \cdot \mathbf{d}(\mathbf{p})] \psi_{\mathbf{p}}, \quad (1)$$

where $\psi_{\mathbf{p}}$ is a two-component spinor, and $\int_{\mathbf{p}} \equiv \int \frac{d^3p}{(2\pi)^3}$. A simple diagonalization of the Hamiltonian shows that there are positive and negative energy eigenstates whose energies are given by $\epsilon_{\pm, \mathbf{p}} = \pm d(\mathbf{p}) \equiv \sqrt{|\mathbf{d}(\mathbf{p})|^2}$. In particular, we set

$$\mathbf{d}(\mathbf{p}) = v_0 (p_x, p_y, \frac{1}{2b} (b^2 - p_z^2)), \quad (2)$$

so that the Hamiltonian has two isotropic Weyl nodes (valleys) around $\mathbf{b}_{\pm} = (0, 0, \pm b)$. For small momenta around these nodes, $\delta\mathbf{p}_{\pm} \equiv \mathbf{p} - \mathbf{b}_{\pm}$, one obtains the low energy Hamiltonians, one for each chirality ($\pm \equiv L/R$),

$$\mathcal{H}_{L,R}(\delta\mathbf{p}_{\pm}) = \delta p_{\pm,x} \sigma_x + \delta p_{\pm,y} \sigma_y \pm \delta p_{\pm,z} \sigma_z, \quad (3)$$

where we have set the Fermi velocity $v_0 \equiv 1$, as is also done throughout the rest of this work. The nodes are thus separated by a distance $2b$. Importantly, we assume that the chemical potential is the same for both valleys, and much larger than the temperature T . Without loss of generality, we assume that the chemical potential is positive, meaning that the occupied valence band has no impact in the transport properties and can be neglected. In addition we also assume that $p_f < b \equiv |\mathbf{b}|$ as well in order to have a well defined chirality for each valley.

Longitudinal acoustic phonons have on-shell isotropic energies $\omega_{\mathbf{q}} = c|\mathbf{q}| \equiv cq$, where c is the (dimensionless) speed of sound measured in units of v_0 . For realistic WSM it turns out that $c \ll 1$. In the present work phonons interact with electrons through a deformation potential term [10] (neglecting umklapp processes):

$$H_{\text{e-ph}} = \int_{\mathbf{p}', \mathbf{p}, \mathbf{q}} g_{\mathbf{p}'+\mathbf{q}, \mathbf{p}}^{\mathbf{q}} (a_{\mathbf{q}} + a_{\mathbf{q}}^{\dagger}) \psi_{\mathbf{p}'+\mathbf{q}}^{\dagger} \psi_{\mathbf{p}}. \quad (4)$$

The operator $a_{\mathbf{q}}$ ($a_{\mathbf{q}}^{\dagger}$) destroy (create) a phonon with momentum \mathbf{q} , and the electron-phonon coupling is given by

$$g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}} = \sqrt{\frac{C}{2\omega_{\mathbf{q}}}} (\mathbf{p}' - \mathbf{p}) \cdot \hat{\mathbf{q}}, \quad (5)$$

where C is some constant regulating the strength of the electron-phonon interaction that has dimension of energy⁻² after setting $\hbar = v_0 = 1$ and $\hat{\mathbf{q}} = \mathbf{q}/|\mathbf{q}|$. In the literature $C \equiv D$

The effective coupling between the relevant positive energy solutions of (1) is

$$g_{\mathbf{p}', \mathbf{p}}^{\text{eff } \mathbf{q}} = g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}} \langle +\mathbf{p}' | +\mathbf{p} \rangle, \quad (6)$$

where $|+\mathbf{p}\rangle$ is the positive energy eigenstate of the Hamiltonian (see Supplementary Material [17] section A). Note that because of overlap term $\langle +\mathbf{p}' | +\mathbf{p} \rangle$ the effective fermion-phonon coupling is now sensitive to chirality flips in the scattering processes involving different valleys, as can be checked by expressing \mathbf{p}' and \mathbf{p} in terms of $\delta\mathbf{p}_{\pm'}$ and $\delta\mathbf{p}_{\pm}$. In the rest of this work, the label \mathbf{p} will be used instead of $\delta\mathbf{p}_{\pm}$ to refer to the momenta with respect to the Weyl nodes. For chirality-violating processes where confusion could arise, the momentum around the right-handed node will simply be altered as $\mathbf{p} \rightarrow \mathbf{p} + 2\mathbf{b}$, setting it to the reference frame of the left-handed node.

The phonon propagator is given by

$$\mathcal{D}(\mathbf{q}, \omega) = \frac{2\omega_{\mathbf{q}}}{\omega^2 - \omega_{\mathbf{q}}^2 + i\omega_{\mathbf{q}}\Gamma_{\mathbf{q}}}. \quad (7)$$

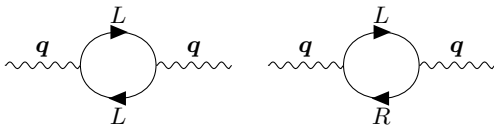

Figure 1. Intravalley and intervalley contributions to the phonon linewidth from the electron-phonon interaction. The bubble diagram with two R fermions provides the same contribution as the the first diagram.

We have included the effects of interactions through a small but non-vanishing phonon linewidth $\Gamma_{\mathbf{q}} \ll \omega_{\mathbf{q}}$. Here we focus on the electron-phonon interaction (4) as the dominant source of this phonon linewidth, represented to lowest order in perturbation theory by the diagrams in Fig.(1), i.e., $\Gamma_{\mathbf{q}} = \Gamma_{\mathbf{q}}^{\text{e-ph}}$. In general, other effects like phonon-impurity scattering or anharmonic effects might enhance $\Gamma_{\mathbf{q}}$, so we expect for realistic WSMs,

$$\Gamma_{\mathbf{q}} \geq \Gamma_{\mathbf{q}}^{\text{e-ph}}. \quad (8)$$

B. Boltzmann Equation

The evolution of the distribution function $f_{\lambda}(\mathbf{p}, \mathbf{x})$ for the fermionic quasiparticles with chirality $\lambda = L, R$ is governed by the quantum Boltzmann equation

$$\partial_t f_{\lambda} + \mathbf{F} \cdot \nabla_{\mathbf{p}} f_{\lambda} + \mathbf{v}_{\lambda} \cdot \nabla_{\mathbf{x}} f_{\lambda} = -\mathcal{I}[f_{\lambda}]. \quad (9)$$

where \mathbf{F} is the external force acting on the particles and $\mathbf{v}_{\lambda} \equiv \nabla_{\mathbf{p}} \epsilon_{\mathbf{p}} = \hat{\mathbf{p}}$ is the group velocity for linearly dispersive WSMs. Note that the λ dependence of the group velocity is implicitly encoded in the reference point for the momentum \mathbf{p} . The collision integral (right hand side of (9)) contains terms arising from the scattering of electrons by impurities, absorption/emission of real phonons and electron-electron interactions:

$$\mathcal{I}[f_{\lambda}] \equiv \mathcal{I}_{\text{imp}}[f_{\lambda}] + \mathcal{I}_{\text{e-ph}}[f_{\lambda}] + \mathcal{I}_{\text{e-e}}[f_{\lambda}]. \quad (10)$$

Electron-electron interactions are the only processes that conserve electron momentum. We do not consider here screened Coulomb interactions, and assume that virtual phonon exchange is the only source of electron-electron interactions.

We also assume that phonons are at thermal equilibrium, following Bose-Einstein distribution,

$$b_0(\omega) = \frac{1}{e^{\beta\omega} - 1}. \quad (11)$$

The electric (\mathbf{J}_{E}) and heat (\mathbf{J}_{T}) currents can be obtained from the solution f_{λ} of (9):

$$\mathbf{J}_{\text{E,T}} \equiv \sum_{\lambda} \int_{\mathbf{p}} q_{\text{E,T}}^{\lambda} \mathbf{v}_{\lambda} f_{\lambda}, \quad (12)$$

where $q_{\text{E}}^{\lambda} \equiv q_{\text{E}} \equiv e$ and $q_{\text{T}}^{\lambda} \equiv q_{\text{T}} \equiv (p - p_f)$ are the chirality-independent charges associated to each current, and $p \equiv |\mathbf{p}|$.

In thermal equilibrium, fermions follow the Fermi-Dirac distribution

$$f_0 \equiv f_0(p) = \frac{1}{e^{\beta(p-p_f)} + 1}, \quad (13)$$

for which the collision integral (10) and the currents (12) identically vanish. We thus analyze the non-equilibrium perturbative response to small electric fields and thermal gradients. As usual, the nonlinear Boltzmann equation (9) can be linearized by writing $f_{\lambda} = f_0 + \delta f_{\lambda}$ and keeping only the terms δf_{λ} that depend linearly with the external fields. Eq.(9) then becomes

$$\hat{\mathbf{p}} \cdot [e\mathcal{E} - \beta(p - p_f) \nabla T] \beta f_0 [1 - f_0] = -\mathcal{I}[f_0 + \delta f_{\lambda}], \quad (14)$$

where $\mathcal{E} \equiv \mathbf{E} + \frac{1}{e} \nabla \mu$ is the electrochemical force and ∇T the temperature gradient. We also assume that the system size is much larger than any other scale in the problem. In absence of external magnetic fields that trigger anomaly-related phenomena, we expect that $\delta f_L = \delta f_R \equiv \delta f$ in Eq.(14) so in practice one only needs to study the Boltzmann equation for a single chirality, even when chirality-flipping processes are taken into account. Due to the form of the LHS of Eq.(14), it is convenient to parametrize δf as

$$\delta f = \beta^2 f_0 [1 - f_0] [\mathcal{X}_{\text{E}}(\mathbf{p}) \cdot e\mathcal{E} - \mathcal{X}_{\text{T}}(\mathbf{p}) \cdot \nabla T], \quad (15)$$

where $\mathcal{X}_{\text{E,T}}$ are dimensionless vector perturbations. Substituting this expression into (14) and separating the electric and thermal contributions, one formally obtains a vector equation

$$\mathcal{S}_{\text{E,T}} = \mathcal{C} \mathcal{X}_{\text{E,T}}, \quad (16)$$

where the source term is defined as $\mathcal{S}_{\text{E,T}} \equiv \hat{q}_{\text{E,T}} \hat{\mathbf{p}}$. The quantities $\hat{q}_{\text{E}} \equiv 1$ and $\hat{q}_{\text{T}} \equiv \beta(p - p_f)$ are the dimensionless charges for the sources, and the operator \mathcal{C} on the RHS is the vectorized version of the collision integral acting on the vector functions $\mathcal{X}_{\text{E,T}}$. Although isotropy is technically broken in our model through the internodal vector \mathbf{b} , we assume that the solution is isotropic and hence postulate that $\mathcal{X}_{\text{E,T}}(\mathbf{p}) = \mathcal{X}_{\text{E,T}}(\epsilon_{\mathbf{p}}) \mathbf{v} = \mathcal{X}_{\text{E,T}}(p) \hat{\mathbf{p}}$. For isotropic systems, the currents (12) are related to the external fields through the Onsager transport coefficients

$$\begin{pmatrix} \mathbf{J}_{\text{E}} \\ \mathbf{J}_{\text{T}} \end{pmatrix} = \begin{pmatrix} L_{\text{EE}} & L_{\text{ET}} \\ L_{\text{TE}} & L_{\text{TT}} \end{pmatrix} \begin{pmatrix} e\mathcal{E} \\ \nabla T \end{pmatrix}, \quad (17)$$

which for our model read

$$L_{\text{AB}} = \frac{4\beta^2}{3(2\pi)^2} \int dp p^2 f_0 [1 - f_0] q_{\text{A}}(p) \mathcal{X}_{\text{B}}(p). \quad (18)$$

Note that an extra factor of 2 has been introduced to account for the effect of both valleys/chiralities. The elec-

tric conductivity as well as the open-circuit and closed-circuit thermal conductivities are respectively defined as

$$\begin{aligned}\sigma &\equiv e^2 L_{EE}, \quad \bar{\kappa} \equiv L_{TT}, \\ \kappa &\equiv L_{TT} - \frac{L_{TE}L_{ET}}{L_{EE}}.\end{aligned}\quad (19)$$

The thermopower is given by $\alpha \equiv eL_{TE} = e\beta^{-1}L_{ET}$, and the latter equality is due to Onsager reciprocity[18].

C. Variational Approach

To solve Eqs.(16), we make use of the standard variational approach [19–21]. Introducing the inner product

$$(\mathcal{F}, \mathcal{G}) \equiv \int \frac{d^3p}{(2\pi)^3} \beta f_0(p) [1 - f_0(p)] \mathcal{F}(\mathbf{p}) \cdot \mathcal{G}(\mathbf{p}), \quad (20)$$

the following functional is defined:

$$\mathcal{Q}_{E,T}[\mathcal{X}_{E,T}] \equiv (\mathcal{X}_{E,T}, \mathbf{S}_{E,T}) - \frac{1}{2}(\mathcal{X}_{E,T}, \mathbf{C}\mathcal{X}_{E,T}). \quad (21)$$

Eqs.(16) are then obtained by applying the variational principle on this functional $\delta\mathcal{Q}_{E,T}/\delta\mathcal{X}_{E,T} = 0$. The issue of solving the Boltzmann equation (14) can hence be converted into an N -dimensional algebraic problem by expanding $\mathcal{X}_{E,T}$ into an arbitrary functional basis $\{F^n\}_{n=0}^{N-1}$, i.e., $\mathcal{X}_{E,T}(p) = \mathbf{x}_{E,T} \cdot \mathbf{F}(p)$. Now the Boltzmann equation (16) becomes a linear equation for the vector of unknown coefficients $\mathbf{x}_{E,T}$,

$$\mathbf{S}_{E,T} = \mathbf{C} \mathbf{x}_{E,T}, \quad (22)$$

where the components of the source vector are $S_{E,T}^n \equiv (F^n \hat{\mathbf{p}}, \mathbf{S}_{E,T})$ and the collision matrix components are given by $C^{nm} \equiv (F^n \hat{\mathbf{p}}, \mathbf{C}[F^m \hat{\mathbf{p}}])$. If \mathbf{C} is an invertible operator, Eq.(22) has a unique solution and the transport coefficients will read $L_{AB} \propto \mathbf{S}_A \mathbf{C}^{-1} \mathbf{S}_B$. For the conductivities it implies

$$\begin{aligned}\sigma &= \frac{2e^2\beta}{3} \mathbf{S}_E^\dagger \mathbf{C}^{-1} \mathbf{S}_E, \quad \bar{\kappa} = \frac{2}{3} \mathbf{S}_T^\dagger \mathbf{C}^{-1} \mathbf{S}_T, \\ \alpha &= \frac{2e\beta}{3} \mathbf{S}_E^\dagger \mathbf{C}^{-1} \mathbf{S}_T = \frac{2e\beta}{3} \mathbf{S}_T^\dagger \mathbf{C}^{-1} \mathbf{S}_E.\end{aligned}\quad (23)$$

Again, the latter equality in (23) is just the well-known Onsager reciprocity. In the case at hand, it easily proven using (22) and the hermiticity of \mathbf{C} .

The expressions in (23) are meaningful if the collision matrix is invertible as it happens when momentum-relaxing processes are considered. However, in the presence of exclusively momentum-conserving processes (that also conserve chirality, as we will see later) \mathbf{C} would have a zero-mode associated with momentum conservation and given by the function $F^0(p) = \beta p$. In such a scenario the conductivities (23) would be infinite with the electric field/thermal gradient accelerating electrons indefinitely, preventing any steady state. This is indeed the case for the electric conductivity σ , where a net movement of the electron fluid is needed to carry charge

between electrodes, but not necessarily for the thermal conductivity κ , measured in short-circuit conditions. In this short-circuit scenario, heat can be transferred among electronic degrees of freedom without the need of a net fluid movement, so it is expected to be finite even for a purely momentum-conserving system.

Since \mathbf{C}_{e-e} is hermitian, it can be diagonalized through an orthogonal basis $\{F^n\}_{n=0}^{N-1}$, where $F^0(p) = \beta p$ is the zero-mode described above. If a small momentum-relaxing perturbation to the total collision matrix of the form $\tau_{\text{mr}}^{-1} \mathbf{1}$ is introduced so that $\mathbf{C} = \tau_{\text{mr}}^{-1} \mathbf{1} + \mathbf{C}_{e-e}$, then its inverse is given by

$$\mathbf{C}^{-1} = \begin{pmatrix} \tau_{\text{mr}} & 0 & \cdots \\ 0 & (\tau_{\text{mr}}^{-1} + \tau_1^{-1})^{-1} & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix}, \quad (24)$$

where τ_n^{-1} is the eigenvalue corresponding to the basis function F^n . Plugging this into the equation for the electric conductivity (23) and taking the momentum conserving limit $\tau_{\text{mr}} \gg \tau_n$ (which is relevant for studying hydrodynamic effects) one obtains

$$\sigma \propto \tau_{\text{mr}} (S_E^0)^2, \quad (25)$$

which in the $\tau_{\text{mr}} \rightarrow \infty$ limit is infinite, as expected. In our case where $p_f \gg T$, one can go further by noticing that at leading order, the zero-mode in the functional basis is related to the source term $\mathbf{p} \approx p_f \mathbf{S}_E$. Since the zero-mode $F^0(p)$ is orthogonal to all other basis vectors, $0 = P^n \approx S_E^n$ for all $n > 0$. Plugging this into Eq.(19), the expression in Eq.(25) is automatically recovered, independently of the hierarchy of τ_{mr} with respect to τ_n .

In the case of κ , one can plug in Eq.(23) into the definition given in Eq.(19) and find that $\kappa \propto \sigma^{-1} \text{Tr} \left[(\mathbf{\Sigma} \mathbf{C}^{-1})^2 \right]$, where $\Sigma^{ij} \equiv S_E^i S_T^j - S_T^i S_E^j$. Since $\mathbf{\Sigma}$ is antisymmetric, the only possibly non-convergent term in the large τ_{mr} limit, which is proportional to $[C^{-1,00}]^2 = \tau_{\text{mr}}^2$, vanishes. In fact, only terms in the trace proportional to τ_{mr} survive in the momentum-conserving limit since the electrical conductivity $\sigma \propto \tau_{\text{mr}}$ in the denominator renders their contribution finite. The resulting expression for κ in the momentum-conserving limit is

$$\kappa \propto \sum_{n=1}^{N-1} \tau_n \left(S_T^n - \frac{S_T^0}{S_E^0} S_E^n \right)^2. \quad (26)$$

In our model, $\mathbf{S}_T = \mathbf{p} - p_f \mathbf{S}_E$, where \mathbf{p} is the zero-mode. Using again that $P^n = 0$ for $n > 0$, the thermal conductivity can be expressed as

$$\kappa = \frac{2}{3} \left(\frac{P^0}{S_E^0} \right)^2 \bar{\mathbf{S}}_E^\dagger \bar{\mathbf{C}}^{-1} \bar{\mathbf{S}}_E, \quad (27)$$

where the $\bar{\mathbf{S}}_E$ and $\bar{\mathbf{C}}$ are the respective projections of \mathbf{S}_E and \mathbf{C} into the subspace orthogonal to the zero mode, where $\bar{\mathbf{C}}$ is invertible. Eq.(27) is independent of the basis chosen for the subspace orthogonal to the zero mode.

Physically speaking, momentum-conserving effects are projected out as they are irrelevant for the short-circuited system where κ is measured. The expression for the thermal conductivity (27) is valid for any system described by a Dirac Hamiltonian such as graphene. A similarly simple expression can be derived for systems with a quadratic dispersion relation, where $\mathbf{S}_E \propto \mathbf{p}$.

The discussion in the preceding paragraphs is generic and qualitative. To derive quantitative results for the thermoelectric conductivities, it is necessary to adopt a concrete set of basis functions. For our purposes, it is enough to choose $\{F^n\}_{n=0}^1$ with

$$F^0(p) = \beta p, \quad F^1(p) = 1. \quad (28)$$

As just argued, $F^0(p)$ is useful to distinguish momentum-relaxing and momentum-conserving effects in the momentum-conserving limit. In our model, we consider just one further basis function F^1 , from which the perpendicular subspace to F^0 needed to calculate κ (27) can be extracted through the Gram-Schmidt method. In the Fermi liquid regime $p_f \gg T$, other functions are not needed, as they only contribute with subleading terms in the Sommerfeld expansion with the small parameter $(\beta p_f)^{-1}$. This implies that the result (27) is in fact exact at leading order in T/p_f using only the basis (28).

Returning to our model, electrons can interact with impurities in the material, real phonons through emission and absorption, and other electrons through virtual phonons (10). Impurities are considered through a relaxation time approximation (RTA),

$$\mathcal{I}_{\text{imp}}[f] \equiv -\frac{\delta f}{\tau_{\text{imp}}}, \quad (29)$$

i.e., the strength of impurity scattering is accounted for by the parameter τ_{imp} . In the matrix form for the Boltzmann equation given in (22), this is equivalent to $\mathbf{C}_{\text{imp}} = \tau_{\text{imp}}^{-1} \mathbf{1}$. This shows that impurities relax all

modes equally, implying that, for impurity-collision dominated systems, $\tau_\sigma = \tau_\kappa$ and non-violation of the WF law.

On the other hand, phonon emission and absorption by electrons is a well-known mechanism [10, 19] leading to $\tau_\sigma \neq \tau_\kappa$ and an explicit violation of the WF law at small temperatures. At large temperatures however, the WF law is restored. Details on the derivation of these conclusions are given in [17]. We also show that, at temperatures above the Bloch-Grüneisen temperature T_{BG} ,

$$\tau_{\sigma/\kappa, \text{e-ph}}^{-1} = \beta^{-1} \frac{2(Cp_f^2)}{3(2\pi)c^2} \cdot \begin{cases} \frac{5}{2} & \text{if } T \gg T_{\text{BG,W}}, \\ 1 & \text{if } T \ll T_{\text{BG,W}}, \end{cases} \quad (30)$$

where the difference in temperature regimes comes from the fact that for $T \ll T_{\text{BG,W}} \equiv 2cb$, chirality-breaking phonon absorption/emission is suppressed as real/thermal phonons do not have enough energy to make the jump between valleys. At temperatures $T \ll T_{\text{BG}}$ chirality-breaking processes are of course still suppressed but chirality-conserving ones lead to

$$\tau_{\sigma, \text{e-ph}}^{-1} = \beta^{-5} \frac{12g_5 C}{(2\pi)c^6 p_f^2} = \frac{(\beta p_f)^{-2}}{c_2 c^2} \cdot \tau_{\kappa, \text{e-ph}}^{-1}. \quad (31)$$

and the WF law is violated when these relaxation times dominate, $L/L_0 = \tau_\kappa/\tau_\sigma \neq 1$. In (31), c_2 and g_5 are $O(1)$ constants [17].

III. ELECTRON-ELECTRON COLLISIONS

In this section we consider the effects of normal (momentum-conserving) electron-electron interactions mediated by virtual phonons in transport, the primary focus of this work. We first study the collision integral for intravalley processes $L, L \rightarrow L, L$, and then extend it to the full system which also includes the R node. For intravalley processes the collision integral in the action functional (21) is given by

$$(\mathcal{X}, \mathcal{C}_{\text{e-e}} \mathcal{X})^{\text{intra}} = \frac{1}{2} \cdot \frac{1}{4} \beta^2 \int_{\mathbf{p}} \int_{\mathbf{k}} \int_{\mathbf{p}'} \int_{\mathbf{k}'} |M_{LL}^{LL}(\mathbf{p}, \mathbf{k}; \mathbf{p}', \mathbf{k}')|^2 f_0(p) f_0(k) [1 - f_0(p')] [1 - f_0(k')] \\ (2\pi)^4 \delta(\mathbf{p} + \mathbf{k} - \mathbf{p}' - \mathbf{k}') \delta^{(3)}(\mathbf{p} + \mathbf{k} - \mathbf{p}' - \mathbf{k}') |\Delta \mathcal{X}|^2, \quad (32)$$

where $|\Delta \mathcal{X}|^2 \equiv [\mathcal{X}(p)\hat{\mathbf{p}} + \mathcal{X}(k)\hat{\mathbf{k}} - \mathcal{X}(p')\hat{\mathbf{p}}' - \mathcal{X}(k')\hat{\mathbf{k}}']^2$ and $|M_{LL}^{LL}(\mathbf{p}, \mathbf{k}; \mathbf{p}', \mathbf{k}')|^2$ is the square of the scattering amplitude for two left-handed fermions with momenta \mathbf{p} and \mathbf{k} to scatter to two final electron states with momenta \mathbf{p}' and \mathbf{k}' of the same chirality. To see how the action functional collision integral (32) is derived from the collision integral $\mathcal{I}_{\text{e-e}}[f_\lambda]$ appearing in the Boltzmann equation (10), see section F of [17]. The scattering can occur on two different channels, depending on how the initial states are connected to the final states, as rep-

resented via Feynman diagrams in Fig.(2). We call the channel where \mathbf{p} is connected to \mathbf{p}' the t -channel, and the one where \mathbf{p} is connected to \mathbf{k}' the u -channel, following the convention in Quantum Electrodynamics. The scattering amplitude for the t -channel is given by

$$A_t = -C \frac{q^2}{\omega^2 - \omega_{\mathbf{q}}^2 + i\omega_{\mathbf{q}} \Gamma_{\mathbf{q}}} \langle +\mathbf{p}' | +\mathbf{p} \rangle \langle +\mathbf{k}' | +\mathbf{k} \rangle. \quad (33)$$

Note that since we are considering left chiral states, technically $|+\mathbf{p}\rangle$ represents $|+, -\mathbf{b} + \delta\mathbf{p}\rangle$. Here $\mathbf{q} \equiv$

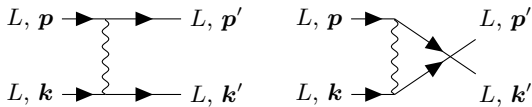

Figure 2. Intranode Feynman diagrams, with the t -channel corresponding to A_t (left) and the u -channel corresponding to A_u (right).

$$(\mathcal{X}, \mathcal{C}_{e-e} \mathcal{X})^{\text{intra}} = \frac{\beta^2}{4(2\pi)^6} \int_0^{q_D} dq \int_{-q}^q d\omega \int_{\frac{q-\omega}{2}}^{\infty} dp pp' \int_{\frac{q+\omega}{2}}^{\infty} dk kk' \int_0^{2\pi} d\varphi_{q,pk}$$

$$|M_{LL}^{LL}|^2 (\beta\omega)^2 b_0(\omega) [1 + b_0(\omega)] f_0(p) [1 - f_0(p)] f_0(k) [1 - f_0(k)] |\Delta\mathcal{X}|^2, \quad (34)$$

where now p' and k' should be understood as shorthands for $p' \equiv p + \omega$ and $k' \equiv k - \omega$. A Debye cutoff q_D to the phonon momentum has been introduced, although it will not have any effect due to the assumption that $T_{\text{BG}} < T_D$, which effectively restricts q to values under $2p_f < q_D$. To proceed further analytically, it is necessary to study this integral in asymptotic temperature regimes.

A. High Temperatures

The full square of the scattering amplitude equates to $|M_{LL}^{LL}|^2 = |A_t|^2 + |A_u|^2 - 2\text{Re}[A_t^* A_u]$. The $|A_t|^2$ and $|A_u|^2$ give identical contributions to the collision integral as can be seen by relabeling $\mathbf{p}' \leftrightarrow \mathbf{k}'$ in the original integral (32). These induce term of the form

$$I_\omega \equiv \int_{-1}^1 \frac{f(x)}{[(x-c)^2 + \frac{\Gamma_q^2}{4q^2}][(x+c)^2 + \frac{\Gamma_q^2}{4q^2}]} dx, \quad (35)$$

inside the q integral, where $x \equiv \omega/q$ is a dimensionless form of the virtual phonon energy and $f(x)$ is some function. The residue theorem can be used to perform the integral, with the enclosing curve being far enough from the poles appearing in the denominator of (35). If $f(x)$ contains no further poles within this contour, then expanding $f(x)$ in a Taylor series around $x = 0$ and performing the integral evaluates to

$$I_\omega = \frac{\pi q}{\Gamma_q} \left[\frac{1}{c^2} f(0) + \frac{1}{2} f''(0) \right] + O(1), \quad (36)$$

where the $O(1)$ refers to terms that are proportional to a power of 0 or more of the small parameters c and $\Gamma_q/(2q)$. A similar procedure can be carried out for the interference term that depends on $2\text{Re}[A_t^* A_u]$ (see section F 1 a of [17]). However, in that case, the results are of a higher-order in the expansion parameters than the non-interference contribution (36), and can thus be neglected.

$\mathbf{p}' - \mathbf{p} = \mathbf{k} - \mathbf{k}'$ is the virtual phonon momentum and $\omega \equiv p' - p = k - k'$ is its energy. The u -channel amplitude is obtained by interchanging $\mathbf{p}' \leftrightarrow \mathbf{k}'$. The total scattering amplitude is then given by $M_{LL}^{LL} \equiv A_t - A_u$, where the minus sign is due to the fermion exchange from the t to the u diagrams. After some manipulations, one finds that

The next-to leading order term proportional to $f''(0)$ is considered because the contribution from the leading term proportional to $f(0)$ is actually vanishing at the leading order in the Sommerfeld expansion, where $p = k = p' = k' = p_f$ and the $|\Delta\mathcal{X}|^2$ term in (32) is easily seen to vanish because of momentum conservation. This is not the case for the $f''(0)$ term, which is non-vanishing at the leading order in the Sommerfeld expansion. This implies that the ratio between the contributions of $f(0)$ and $f''(0)$ is of order $(T/cp_f)^2 \sim (T/T_{\text{BG}})^2$. Therefore, for temperatures above the Bloch-Grüneisen temperature, the $f(0)$ term dominates over the one proportional to $f''(0)$ so, in practice, only the $f(0)$ term is relevant in this subsection.

The assumption that $f(x)$ has no other poles inside the contour only applies for $T \gg T_{\text{BG}}$ as the Fermi-Dirac distribution functions contained in $f(x)$ also have imaginary poles at the Matsubara frequencies, being the lowest of order $\beta^{-1} = T$. Therefore, when $T \gg T_{\text{BG}}$, we can integrate along contours not containing Matsubara poles. This is not the case if $T \lesssim T_{\text{BG}}$, to be considered in the next subsection.

Assuming that the dominant contribution to the phonon linewidth comes from electron-phonon interactions, that is, Eq.(8) is an (approximate) equality, one finds that

$$(\mathcal{X}, \mathcal{C}_{e-e} \mathcal{X})^{\text{intra}} = \frac{4c_2(Cp_f^2)\beta^{-2}}{3(2\pi)^3 c^2} [X'(p_F)p_f]^2. \quad (37)$$

where $X(p) \equiv \mathcal{X}(p)/p$ and $c_2 =$. Expanding $X(p)$ as a linear combination of the basis functions (28) to extract the matrix components of \mathcal{C}_{e-e} , only the C_{e-e}^{11} component is non-zero, as expected from the fact that that $F^0(p)$ is a zero-mode. For this reason, this collision integral does not contribute to the electric conductivity, again as expected from Eq.(25). On the other hand, it contributes to the thermal conductivity as much as the interaction

with real phonons,

$$\tau_{\kappa, e-e}^{-1} = \tau_{\kappa, e-ph}^{-1}. \quad (38)$$

In physical terms, this can be understood from the fact that at $T > T_{BG}$, the dominant contribution to the electron-electron collision integral is from virtual phonons satisfying the on-shell condition $\omega = cq$ stemming from the poles in Eq.(35). It is natural to expect that the processes in fig. (2) share the same time scale as the emission and absorption of real phonons, $\tau_{e-e}^{-1} = \tau_{\text{emission}}^{-1} + \tau_{\text{absorption}}^{-1} \equiv \tau_{e-ph}^{-1}$.

If impurity scattering is negligible (which is natural to expect at sufficiently high temperatures), and ignoring chirality-violating e-e processes, then one sees that

$$L = \frac{L_0}{2}, \quad (39)$$

as the thermal conductivity would now have half the relaxation time of the electric conductivity, oblivious to electron-electron interactions. This equality is only valid when the inequality in Eq.(8) saturates. For any larger phonon linewidth, electron-electron scattering mediated by phonons would be suppressed at $T > T_{BG}$. Physically this corresponds to the scenario where the on-shell virtual phonons, acting like real phonons, have decay channels stronger than those of emission and absorption by electrons, thus suppressing the emission and absorption-dependent processes depicted in Fig.(2). In this limit, $L \rightarrow L_0$, independently on whether chirality-violating processes are considered or not.

B. Low Temperatures

At temperatures below T_{BG} the Matsubara poles start to play a role and the approximation in Eq.(36) is no longer valid. Instead of attempting to calculate the contribution of these new poles, we make the observation that, in this regime, the Bose-Einstein distribution in Eq.(34) can no longer be approximated by its $\beta\omega \rightarrow 0$ limit. We expect then that, for $T \ll T_{BG}$, the equilibrium Bose-Einstein distribution will be the dominating contribution, fixing $\omega \sim \beta^{-1}$ instead of the on-shell condition $\omega \sim cq$. This observation, together with the defining condition for this temperature regime, implies that $\omega \ll \omega_{\mathbf{q}}$ and hence the ω dependence of the propagator in Eq.(7) can be dropped. Consequently the scattering amplitude for the t -channel becomes

$$\begin{aligned} A_t &= C \frac{q^2}{\omega_{\mathbf{q}}^2} \langle +\mathbf{p}' | +\mathbf{p} \rangle \langle +\mathbf{k}' | +\mathbf{k} \rangle \\ &\simeq \frac{C}{c^2} \langle +\mathbf{p}' | +\mathbf{p} \rangle \langle +\mathbf{k}' | +\mathbf{k} \rangle, \end{aligned} \quad (40)$$

where we have dropped the phonon linewidth $\Gamma \ll \omega_{\mathbf{q}}$ as it is no longer necessary to make the integral convergent.

In the $T \gg T_{BG}$ regime we argued that the interference term in the square of the scattering amplitude could be dropped as it was subleading in the c and $\Gamma/(2q)$ expansion stemming from Eq.(36). That statement is no longer valid, as the low temperature approximation for the amplitude Eq.(40) obviously has no poles, and we need to consider the interference contribution from $-2\text{Re}[A_t^* A_u]$. The physical intuition for this is that for temperatures above T_{BG} , phonons behave classically and quantum interference effect is negligible. For temperatures below T_{BG} , phonons regain their quantum behavior and interference terms are no longer subleading. Nevertheless, the simple form of the amplitudes in Eq.(40) makes calculations simple. For instance, one can show that, in the low temperature limit,

$$|M_{LL}^{LL}|^2 = \frac{C^2}{4c^4} (1 - \cos \theta_{pk})^2, \quad (41)$$

where θ_{pk} is the angle between \mathbf{p} and \mathbf{k} . Note that the equivalent intraband square of the scattering amplitude would vanish in a model diagonal in the electron basis of the Hamiltonian, as then the wavefunction overlaps would be trivial and $A_t = A_u$ in Eq.(40). This would mean that higher order terms in ω would be required for the scattering amplitude, which would suppress the contribution of the collision integral by a power of the small parameter T/p_f and hence the contribution of electron-electron scattering mediated by phonons to transport effects.

After some intermediate calculations, the collision integral reduces to

$$(\mathcal{X}, C\mathcal{X})^{\text{intra}} = \frac{2^4 C^2 p_F^7 \beta^{-3}}{35(2\pi)^5 c^4} [4c_2^2 + 2b_4] X'(p_F)^2, \quad (42)$$

where c_2 and b_4 are $O(1)$ numeric constants. The inverse relaxation time $\tau_{\kappa, e-e}^{-1}$ will now scale as T^2 , just like in the case of Coulomb scattering. This is to be expected as, in the case of Quantum Electrodynamics, virtual photons are always in the $T \ll cq$ regime where the ω^2 in the denominator of the photon propagator is negligible, as in the case Coulomb interaction. Numerical prefactors however are obviously different in the case of Coulomb and virtual phonons, obviously.

C. Chirality-violating processes

Until now we have studied processes within an single Weyl node, valid when interactions do not induce changes in the chirality. In Weyl systems, nodal points come in pairs, as is the case for our starting model Eq.(1), one for left (L) and another for right-handed (R) Weyl fermions. Therefore, besides the intraband $(L, L) \rightarrow (L, L)$ scattering processes we had been considering up until now, we should consider $(L, L) \rightarrow (R, R)$, $(L, R) \rightarrow (L, L)$, $(L, R) \rightarrow (L, R)$ etc. Out of all these possibilities, only the process $(L, R) \rightarrow (L, R)$ conserves chirality. While

the associated collision integral is more complicated due to the anisotropic wavefunction overlaps in the square of the scattering amplitude Eq.(A12), the integral is essentially solved in similar fashion to the chirality-conserving situation.

Chirality-violating processes however, are a different story. In the reference frame of one of the nodes and for processes that violate chirality once, such as $(L, R) \rightarrow (L, L)$, Dirac deltas associated to momentum conservation in the collision integrals take the form

$$\delta^{(3)}(\mathbf{p} + \mathbf{k} - \mathbf{p}' - \mathbf{k}' \pm 2\mathbf{b}). \quad (43)$$

For processes that violate chirality twice, such as $(L, L) \rightarrow (R, R)$ we have $\delta^{(3)}(\mathbf{p} + \mathbf{k} - \mathbf{p}' - \mathbf{k}' \pm 4\mathbf{b})$. These Dirac deltas are similar to the ones appearing in umklapp processes with a lattice vector $2\mathbf{b}$ separating two copies of the same Fermi surface. Note however that momentum here is strictly conserved, as can be seen if the momenta are put back into the original reference frame of Eq.(1).

At large temperatures, $T \gg T_{\text{BG,W}}$, the only relevant poles in the ω integral are those provided by the phonon propagator in Eq.(7) so that the expansion in Eq.(36) still holds, making the phonons effectively on-shell. In the limit where the inequality Eq.(8) is saturated, one recovers the result in Eq.(38) and an analogously similar result,

$$(\mathcal{X}_0, \mathcal{C}_{e-e} \mathcal{X}_0)_{\text{h.t.}} = \frac{\beta^4 (4b)^2}{2} \int_{\mathbf{q}} \frac{\Gamma_{e\text{-ph}}^{\text{inter}}(\mathbf{q})}{(\beta\omega_{\mathbf{q}})^2}, \quad (44)$$

where $\Gamma_{e\text{-ph}}^{\text{inter}}$ is the contribution to the phonon linewidth from a $L - R$ fermion bubble. This shows how $\tau_{\sigma, e-e}^{-1}$ is directly related to the linewidth associated to interband processes, which are the only electron scattering processes that can relax the electric current in the system. The contribution to the electric conductivity (44), quadratically dependent on the internodal distance, leads to a Lorenz ratio of the form,

$$L = \frac{1}{2} \left(1 + \frac{16b^2}{10p_f^2} \right) L_0. \quad (45)$$

For temperatures below $T_{\text{BG,W}}$ but still above T_{BG} , electron-electron scattering processes that violate chirality no longer contribute and the Lorenz ratio satisfies the equality in Eq.(39). As in the case of intravalley scattering, this is only valid where the dominant phonon decay channel is associated to scattering with electrons. Otherwise, $L \rightarrow L_0$.

At low temperatures, virtual phonons cannot be considered on-shell. Scattering amplitudes for processes that include more than one chirality involve more complicated wavefunction overlaps but otherwise share the relatively similar simple form of Eq.(41) (see section A of [17]). The integral for the chirality conserving process $(L, R) \rightarrow (L, R)$ is analogous to the one performed for

$(L, L) \rightarrow (L, L)$ in Eq.(42), whereas the one for chirality-violating processes now includes the momentum conservation delta shown in Eq.(43). This delta, along with the restriction that all electron momenta lie on the Fermi sphere, restricts the available phase space as is the case with umklapp scattering [19, 22]. For $2b \geq 4p_f$, these processes are not kinematically allowed. The only interesting parameter space for us to consider is then the relation $2p_f < 2b < 4p_f$, as our model relies on the assumption that $2p_f < b$, where chiralities are well defined. While these integrals can be performed analytically, the end result are somewhat complicated expressions of b , and are written in section (F4) of the Supplementary Material [17] for reference.

IV. DISCUSSION

We have shown how the non-trivial structure of the Weyl Hamiltonian in Eq.(1) had the important consequence of allowing phonon-mediated T^2 inverse relaxation times at low temperatures due to the nontrivial wavefunction overlaps $\langle +\mathbf{k}' | +\mathbf{k} \rangle$. It was the key point also in allowing relaxation of electric current through chirality-violating intervalley scattering, having important properties both at $T > T_{\text{BG}}$ with a non-trivial Lorenz ratio (Eq.(45)) as well as low temperatures, as we will discuss further below. Nevertheless, more unique topological properties of the material fail to make an impact, as the Fermi level is much larger than the Weyl nodes, at least in the absence of a quantum anomaly-inducing magnetic field. Its inclusion is left for future work.

Having discussed already the high-temperature behavior in the previous section, we focus here on the properties at temperatures $T \ll T_{\text{BG}}$, relevant for experimentally observing hydrodynamic signatures. When studying thermoelectric transport in experiments, it is useful to consider the electric and thermal resistivities, which can be conveniently parametrized respectively as $\rho \equiv \sigma^{-1} = A_0 + A_2 T^2 + A_5 T^5$ and $WT \equiv TL_0/\kappa = B_0 + B_2 T^2 + B_3 T^3$, following Ref.[5]. These are plotted in figures (3c-d) in the absence of impurity scattering, whose inclusion would simply amount to an offset in the y-axis. The full Lorenz ratio is plotted in Fig.(3e).

As is clear from our model at low temperatures, A_0 and B_0 are the coefficients associated with impurity scattering, A_2 and B_2 with electron scattering, and A_5 and B_3 with thermal phonon emission/absorption by electrons. In a system that is at some point dominated by electron-electron interactions, one then expects the Lorenz ratio to level out at the constant value $L/L_0 = \rho/WT = \tau_{\sigma, e-e}^{-1}/\tau_{\kappa, e-e}^{-1} = A_2/B_2$. For our model, A_2 is non-vanishing only for $2b < 4p_f$ as otherwise electric current-relaxing intervalley electron-electron interactions are absent. This leads to the curve plotted in Fig.(3f), where the ratio A_2/B_2 is plotted as a function of $2b/p_f$. Note that this quantity is completely indepen-

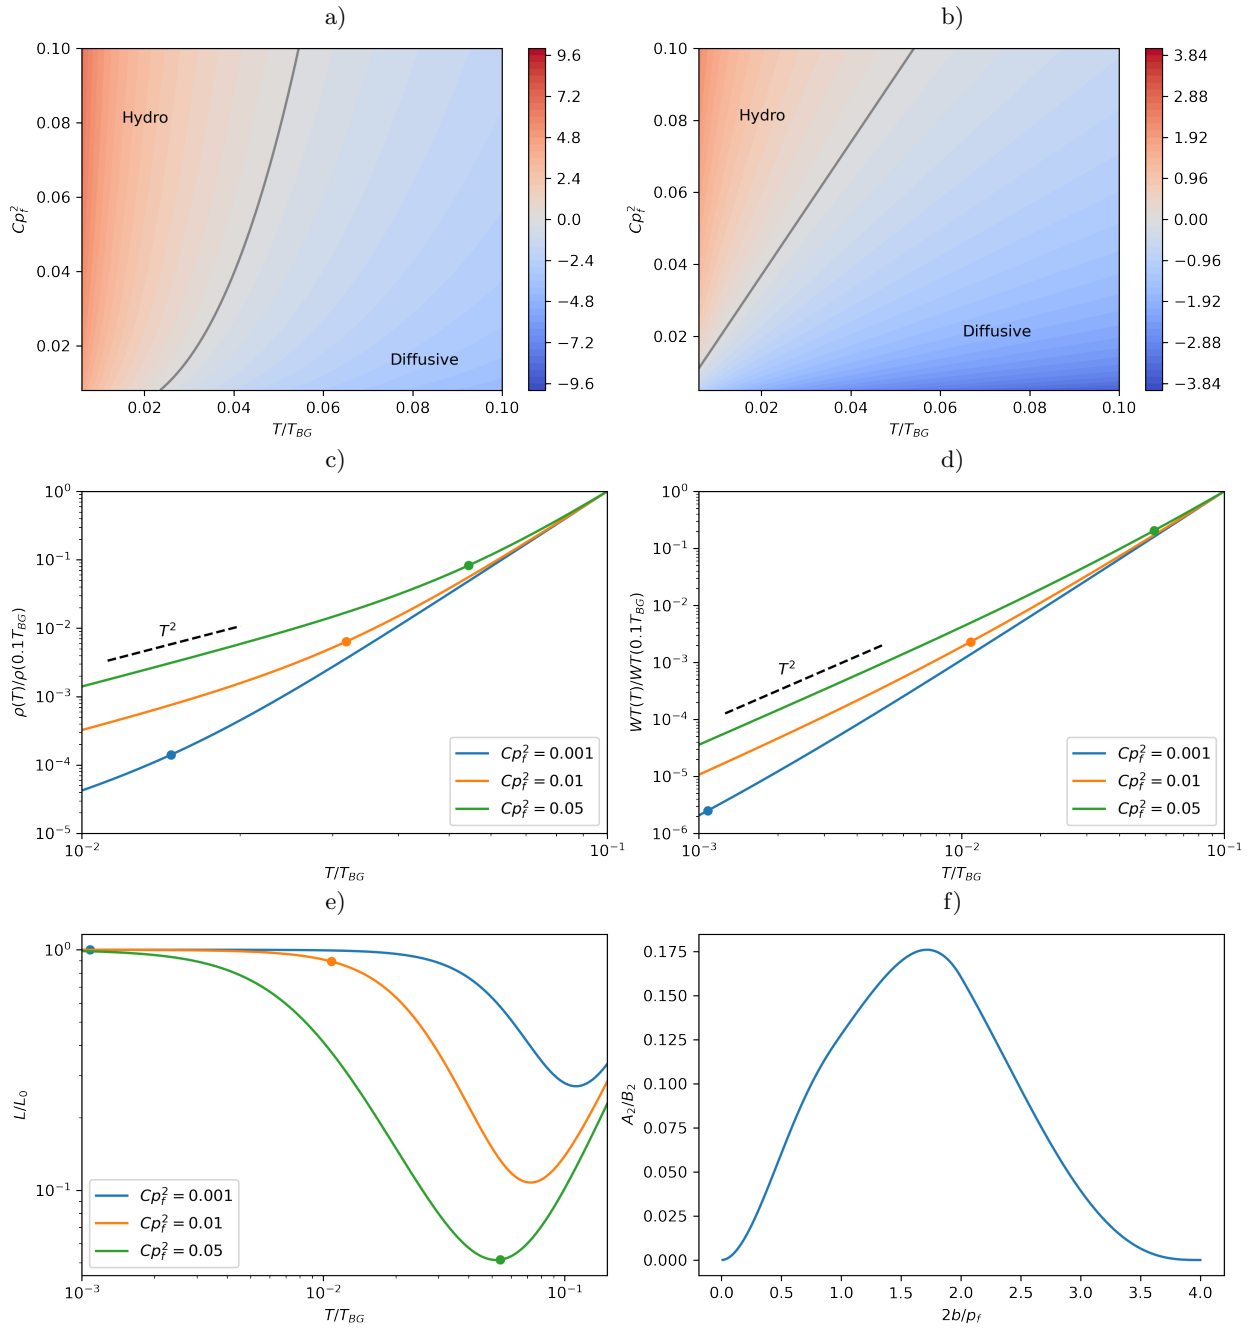

Figure 3. **a** and **b**: Regions where $\tau_{e-e}^{-1}/\tau_{e-ph}^{-1} > 1$, shown in red, and vice versa, shown in blue, for the electric (a) and thermal (b) conductivities. The black lines indicate the border between the regions. **c** and **d**: Electric (c) and thermal (d) conductivities for $T \ll T_{BG}$ for different electron-phonon interaction strengths Cp_f^2 . Points indicate temperature below which electron-electron scattering is stronger than electron-phonon scattering. **d**: Lorenz ratio for $T \ll T_{BG}$. **e**: Ratio between inverse electron-electron relaxation times for the electric and thermal conductivities. All plots are drawn for $p_f = 0.2$ eV and $c = 0.01v_0$. The internodal separation is set to $2b = 2p_f$ for plots a-e.

dent of the electron-phonon coupling C and the phonon velocity c , and therefore only depends on the geometric factor $2b/p_f$. The ratio is expectedly small as intervalley electron-electron scattering contributes much less than the intravalley counterpart present in thermal conduction. However, one would expect that such a ratio could

increase for systems with different geometries or carriers [23, 24]. For example, in a compensated Weyl semimetal with an electron band and a hole band (instead of the two electron bands), chirality-conserving $(L, R) \rightarrow (L, R)$ processes would be able to relax the electron current owing to the fact that the fermions of each valley have group

velocities with the opposite sign. Following the procedure of [25] one can deduce that the ratio A_2/B_2 in such a system takes the form,

$$\frac{A_2}{B_2} = \frac{10\alpha^2 (4305 + 441\alpha^2 - 1980\alpha^4 + 700\alpha^6)}{3 (27090 + 3885\alpha^2 + 63\alpha^4 + 900\alpha^6)}, \quad (46)$$

where $\alpha = \min[T_D/T_{BG}, 1]$. In a system with a sufficiently small Fermi surface so that $T_{BG} < T_D$, this would lead to a value of $A_2/B_2 \sim 0.36$, which is of the same order of the observed values in several materials [5]. In the opposite limit, where $T_{BG} > T_D$, then one has $A_2/B_2 \sim 0.53\alpha^2$, i.e. the Lorenz ratio can become arbitrarily small. This is a similar conclusion to one reached in [25], although a screened Coulomb potential is behind that result, a contribution that is expected to be subdominant with respect to electron-phonon interactions in realistic semimetals [7, 8, 13]. Here, by contrast, this result is reached for a constant potential (modulo structure factors) provided by the low temperature phonon-mediated electron-electron processes (41). Note that, as in our original model, mixed-chirality processes are essential for a T^2 electric conductivity.

Of course, for electron-electron scattering to dominate over electron-phonon scattering, one needs to be in a temperature regime where the electron scattering relaxation times are smaller than those of phonon emission/absorption by electrons. In large part due to the different energy scale-dependence of the electron-phonon relaxation time (31), this will occur at different temperatures for the electric and thermal conductivities. In any case, the stronger the electron-phonon coupling is, the higher these transition temperatures will be. The distinction between these diffusive (electron-phonon dominated) and hydrodynamic (electron-electron dominated) regimes is plotted in Fig.(3a) and Fig.(3b) for different temperatures and different values of the electron-phonon coupling Cp_f^2 . We find that, within our simplified model, the dimensionless parameter that models the electron-phonon coupling strength, Cp_f^2 , needs to somehow reach unrealistically high values $Cp_f^2 \sim 0.1$ [17], for

the T^2 effects to be observable at temperatures of order $0.1T_{BG}$. One should keep in mind however that our model, with isotropic Fermi surfaces and electron-phonon interactions [26, 27], is much simpler than the actual materials used in experiments, where anisotropy has been linked [13, 28] with the enhancement of electron-electron scattering. Future study on the subject should take these complications into account.

It is also important to mention that electron-electron scattering could dominate for some finite temperature window before entering its asymptotic T^2 regime. Indeed, numerically we find that this limit is accurate for temperatures $T \lesssim 0.1T_{BG}$. However, if $\Gamma \approx \Gamma_{e-ph}$, then at temperatures $T > T_{BG}$, the relaxation times for electron scattering and phonon emission/absorption are of the same order as we have shown, so when $T < T_{BG}$, there can be a small window for which $\tau_{\sigma/\kappa, e-e}^{-1} > \tau_{\sigma/\kappa, e-ph}^{-1}$, which is observed in some first-principles calculations [7, 13].

Finally, returning to the discussion on possible hydrodynamic behavior, we note that a calculation of the shear viscosity η through an analogous Boltzmann equation as the one presented here for the thermoelectric conductivities would show that its associated relaxation time $\tau_{\eta, e-e}$ is of the same order as the one for the thermal conductivity since chirality-conserving electron-electron processes would also be present, thus being nonvanishing even for $2b > 4p_f$. We can then expect that for extremely pure sample with size $l \ll \lambda_G$, where $\lambda_G \sim \sqrt{\tau_{\sigma}\tau_{\eta, e-e}}$ is the Gurzhi length, and a strong enough electron-phonon interaction, the electrons will flow in a hydrodynamic regime, with an electric conductivity $\sigma \propto l^2\tau_{\eta, e-e}^{-1}$.

Appendix A: Hamiltonian and Scattering Amplitudes

As mentioned in the main text, a two-band Hamiltonian matrix of the form

$$\mathcal{H}_0(\mathbf{p}) = \mathbf{d}(\mathbf{p}) \cdot \boldsymbol{\sigma}, \quad (\text{A1})$$

where $\mathbf{d} = (d_1, d_2, d_3)^T$ has positive and negative energy $\epsilon_{\pm, \mathbf{p}} = \pm d(\mathbf{p}) \equiv \pm \sqrt{\mathbf{d}^2(\mathbf{p})}$ eigenstates, which are respectively given by ($c \leftrightarrow +$, $v \leftrightarrow -$)

$$|+\mathbf{p}\rangle \equiv \frac{1}{\sqrt{2d(d+d_3)}} \begin{pmatrix} d+d_3 \\ d_1+id_2 \end{pmatrix}, \quad |-\mathbf{p}\rangle \equiv \frac{1}{\sqrt{2d(d+d_3)}} \begin{pmatrix} d_1-id_2 \\ -d-d_3 \end{pmatrix}, \quad (\text{A2})$$

where c stands for conduction band ($+d(\mathbf{p})$) and v for valence band ($-d(\mathbf{p})$). The particle fermion operators are related to the original fermion operators by the unitary transformation $\psi_{\mathbf{p}} = U_{\mathbf{p}} c_{\mathbf{p}}$, where $U_{\mathbf{p}} \equiv (|+\mathbf{p}\rangle, |-\mathbf{p}\rangle)$. In the particle-hole basis, the electron-phonon interaction given by the deformation potential (4) becomes

$$H_{\text{e-ph}} = \int_{\mathbf{p}', \mathbf{p}, \mathbf{q}} g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}} (a_{\mathbf{q}} + a_{\mathbf{q}}^{\dagger}) c_{\mathbf{p}'}^{\dagger} U_{\mathbf{p}'}^{\dagger} U_{\mathbf{p}} c_{\mathbf{p}} \delta^{(3)}(\mathbf{p}' - \mathbf{p} - \mathbf{q}), \quad (\text{A3})$$

For $\mu \gg T$, the effects of the negative energy band are exponentially suppressed, so we ignore its effects from now on. For the fermion-phonon interaction, it implies that we only consider care about the term proportional to $c_{+, \mathbf{p}}^{\dagger} c_{+, \mathbf{p}}$, hence the effective fermion coupling to the relevant fermion sector is given by the expression given in (6), i.e.

$$g_{\mathbf{p}', \mathbf{p}}^{\text{eff } \mathbf{q}} \equiv g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}} \langle +\mathbf{p}' | +\mathbf{p} \rangle, \quad (\text{A4})$$

where for simplicity of notation we have used the label $u_{\mathbf{p}} \equiv u_{+, \mathbf{p}}$, and will continue to do so henceforth. The scattering amplitude for fermion collisions with incoming momenta \mathbf{p}, \mathbf{k} and outgoing momenta \mathbf{p}', \mathbf{k}' mediated by virtual phonons is given by the interference of the t and u channels, $M = A_t - A_u$

$$A_t = -g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}} g_{\mathbf{k}, \mathbf{k}'}^{\mathbf{q}} \mathcal{D}(\mathbf{q}, \omega) \langle +\mathbf{p}' | +\mathbf{p} \rangle \langle -\mathbf{k}' | -\mathbf{k} \rangle, \quad (\text{A5})$$

where $\mathbf{q} = \mathbf{p}' - \mathbf{p}$ and $\omega = d(\mathbf{p}') - d(\mathbf{p})$. The amplitude for the u channel A_u is obtained by exchanging $\mathbf{p}' \leftrightarrow \mathbf{k}'$ in the expression for A_t . The square of the amplitude relevant for the Boltzmann equation can be shown then to be

$$\begin{aligned}
|M|^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') &= |A_t|^2 + |A_u|^2 - 2\text{Re}[A_t^* A_u] = \\
&\left\{ |\mathcal{D}|^2(\mathbf{q}_t, \omega_t) |g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}_t} g_{\mathbf{k}, \mathbf{k}'}^{\mathbf{q}_t}|^2 - \text{Re}[\mathcal{D}^*(\mathbf{q}_t, \omega_t) \mathcal{D}(\mathbf{q}_u, \omega_u)] g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}_t} g_{\mathbf{k}, \mathbf{k}'}^{\mathbf{q}_t} g_{\mathbf{k}', \mathbf{p}}^{\mathbf{q}_u} g_{\mathbf{k}, \mathbf{p}'}^{\mathbf{q}_u} \right\} [1 + \hat{\mathbf{d}}(\mathbf{p}) \cdot \hat{\mathbf{d}}(\mathbf{p}')] [1 + \hat{\mathbf{d}}(\mathbf{k}) \cdot \hat{\mathbf{d}}(\mathbf{k}')] \\
&+ \left\{ |\mathcal{D}|^2(\mathbf{q}_u, \omega_u) |g_{\mathbf{k}', \mathbf{p}}^{\mathbf{q}_u} g_{\mathbf{k}, \mathbf{p}'}^{\mathbf{q}_u}|^2 - \text{Re}[\mathcal{D}^*(\mathbf{q}_t, \omega_t) \mathcal{D}(\mathbf{q}_u, \omega_u)] g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}_t} g_{\mathbf{k}, \mathbf{k}'}^{\mathbf{q}_t} g_{\mathbf{k}', \mathbf{p}}^{\mathbf{q}_u} g_{\mathbf{k}, \mathbf{p}'}^{\mathbf{q}_u} \right\} [1 + \hat{\mathbf{d}}(\mathbf{p}) \cdot \hat{\mathbf{d}}(\mathbf{k}')] [1 + \hat{\mathbf{d}}(\mathbf{k}) \cdot \hat{\mathbf{d}}(\mathbf{p}')] \\
&+ \text{Re}[\mathcal{D}^*(\mathbf{q}_t, \omega_t) \mathcal{D}(\mathbf{q}_u, \omega_u)] g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}_t} g_{\mathbf{k}, \mathbf{k}'}^{\mathbf{q}_t} g_{\mathbf{k}', \mathbf{p}}^{\mathbf{q}_u} g_{\mathbf{k}, \mathbf{p}'}^{\mathbf{q}_u} [1 - \hat{\mathbf{d}}(\mathbf{p}) \cdot \hat{\mathbf{d}}(\mathbf{k})] [1 - \hat{\mathbf{d}}(\mathbf{p}') \cdot \hat{\mathbf{d}}(\mathbf{k}')]. \tag{A6}
\end{aligned}$$

Following the discussion of the main text, a distinction between the behavior at high and low temperatures can be made so as to simplify (A6). At high temperatures $T \gg T_{\text{BG}}$, the interference terms can be dropped. In addition, since the collision integral is symmetric with the exchange $\mathbf{p}' \leftrightarrow \mathbf{k}'$, the square of the amplitude can be effectively be taken to be

$$|M|_{\text{h.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') = \frac{2C^2}{4} \left| \frac{q^2}{\omega^2 - \omega_q^2 + i\omega_q \Gamma_q} \right|^2 [1 + \hat{\mathbf{d}}(\mathbf{p}) \cdot \hat{\mathbf{d}}(\mathbf{p}')] [1 + \hat{\mathbf{d}}(\mathbf{k}) \cdot \hat{\mathbf{d}}(\mathbf{k}')], \tag{A7}$$

where the explicit forms of the electron-phonon coupling (5) and the phonon propagator (7) have been used. At low temperatures $T \ll T_{\text{BG}}$, the ω dependence of the phonon propagators can be dropped at the lowest order in ω/ω_q expansion. The small linewidth can be dropped as well, leading to the cancellation of the first two terms in (A6), so the square of the scattering amplitude at low temperatures has the form

$$|M|_{\text{l.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') = \frac{C^2}{4c^4} [1 - \hat{\mathbf{d}}(\mathbf{p}) \cdot \hat{\mathbf{d}}(\mathbf{k})] [1 - \hat{\mathbf{d}}(\mathbf{p}') \cdot \hat{\mathbf{d}}(\mathbf{k}')]. \tag{A8}$$

So far the discussion is generic, independent of the explicit form of the vector $\mathbf{d}(\mathbf{p})$. If we specialize to the model of a Weyl semimetal given in the main text (2), the above expressions can be specified for the effective model given by the Weyl Hamiltonian (3). For collisions restricted to a single Weyl node, one has

$$|M_{LL}^{LL}|_{\text{h.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') = |M_{RR}^{RR}|_{\text{h.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') = \frac{2C^2}{4} \left| \frac{q^2}{\omega^2 - \omega_q^2 + i\omega_q \Gamma_q} \right|^2 [1 + \cos \theta_{pp'}] [1 + \cos \theta_{kk'}], \tag{A9}$$

$$|M_{LL}^{LL}|_{\text{l.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') = |M_{RR}^{RR}|_{\text{l.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') = \frac{C^2}{4c^4} [1 - \cos \theta_{pk}] [1 - \cos \theta_{p'k'}]. \tag{A10}$$

For chirality conserving collisions between nodes such as $\mathbf{p}L, \mathbf{k}R \rightarrow \mathbf{p}'L, \mathbf{k}'R$, the exchange symmetry $\mathbf{p}' \leftrightarrow \mathbf{k}'$ is lost, so the t and u channel contributions need to be considered separately in the high temperature regime. The amplitudes squared are then

$$\begin{aligned}
|M_{LR}^{LR}|_{\text{h.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') &= \frac{C^2}{4} \left| \frac{q_t^2}{\omega_t^2 - \omega_{q_t}^2 + i\omega_{q_t} \Gamma(q_t)} \right|^2 [1 + \cos \theta_{pp'}] [1 + \cos \theta_{kk'}] \\
&+ \frac{C^2}{4} \left| \frac{q_u^2}{\omega_u^2 - \omega_{q_u}^2 + i\omega_{q_u} \Gamma(q_u)} \right|^2 [1 + \cos \theta_{pp'} - 2 \cos \theta_{pb} \cos \theta_{k'b}] [1 + \cos \theta_{kk'} - 2 \cos \theta_{kb} \cos \theta_{p'b}], \tag{A11}
\end{aligned}$$

$$|M_{LR}^{LR}|_{\text{l.t.}}^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') = \frac{C^2}{4c^4} [1 - \cos \theta_{pk} + 2 \cos \theta_{pb} \cos \theta_{kb}] [1 - \cos \theta_{p'k'} + 2 \cos \theta_{p'b} \cos \theta_{k'b}]. \tag{A12}$$

The case of phonon absorption and emission is simpler. In that case, the the square of the scattering amplitudes are shown to be

$$|M_{\text{abs}}^{LL}|^2(\mathbf{p}, \mathbf{p}', \mathbf{q}) = |M_{\text{emi}}^{LL}|^2(\mathbf{p}, \mathbf{p}', \mathbf{q}) = \frac{Cq^2}{2\omega_q} \cdot \frac{1 + \cos \theta_{pp'}}{2}, \tag{A13}$$

$$|M_{\text{abs}}^{LR}|^2(\mathbf{p}, \mathbf{p}', \mathbf{q}) = |M_{\text{emi}}^{LR}|^2(\mathbf{p}, \mathbf{p}', \mathbf{q}) = \frac{Cq^2}{2\omega_q} \cdot \frac{1 + \cos \theta_{pp'} - 2 \cos \theta_{pb} \cos \theta_{p'b}}{2}. \tag{A14}$$

Note that intranodal RR emission and absorption scattering amplitudes are the same as (A13).

Appendix B: Numeric Integrals

Several numeric integrals appear often in the calculations and are related to the integrals of momenta that include the Fermi-Dirac distribution and the Bose Einstein distribution. We list them here for convenience:

$$c_2 = \int_{-\infty}^{\infty} x^2 \frac{e^x}{(1+e^x)^2} = \frac{1}{2} \int_{-\infty}^{\infty} x^2 \frac{e^x}{(1-e^x)^2} = \frac{\pi^2}{3}, \quad (\text{B1})$$

$$b_4 = \int_{-\infty}^{\infty} x^4 \frac{e^x}{(1-e^x)^2} = \frac{4\pi^4}{15}, \quad (\text{B2})$$

$$g_n = \int_{-\infty}^{\infty} dx \frac{e^x}{(e^x+1)^2} [\zeta(n) - \text{Li}_n(-e^{-x})], \quad (\text{B3})$$

where $g_4 \approx 4.3$, $g_5 \approx 5.2$ and $g_6 \approx 6.1$.

Appendix C: Phonon Linewidth

Considering only intravalley interactions, the phonon linewidth is calculated from the first diagram in Fig. 1 of the main text. To do so, one calculates the self-energy,

$$\Sigma(\mathbf{q}, i\omega_n) = \beta^{-1} \sum_{\mathbf{p}} \sum_{i\nu_m} \left(i g_{\mathbf{p}', \mathbf{p}}^{\text{eff } \mathbf{q}} \right) \left(i g_{\mathbf{p}', \mathbf{p}}^{\text{eff } \mathbf{q}^*} \right) \mathcal{G}_0(\mathbf{k}, i\nu_m) \mathcal{G}_0(\mathbf{k} + \mathbf{q}, i\nu_m + i\omega_n) \quad (\text{C1})$$

$$= -\beta^{-1} \int_{\mathbf{p}} \sum_{i\nu_m} (g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}})^2 \frac{|\langle +\mathbf{p} | +\mathbf{p}' \rangle|^2}{[i\nu_m + p_f - p][i\nu_m + i\omega_n + p_f - p]}, \quad (\text{C2})$$

where $\mathbf{p}' = \mathbf{p} + \mathbf{q}$. Performing the Matsubara sum by integrating over the poles of the propagators,

$$\Sigma(\mathbf{q}, i\omega_n) = \int_{\mathbf{p}} (g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}})^2 |\langle +\mathbf{p} | +\mathbf{p}' \rangle|^2 \left\{ \frac{f_0(p)}{i\omega_n + p - p'} + \frac{f_0(p' - i\omega_n)}{-i\omega_n + p' - p} \right\} = \int_{\mathbf{p}} (g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}})^2 |\langle +\mathbf{p} | +\mathbf{p}' \rangle|^2 \frac{f_0(p) - f_0(p')}{i\omega_n + p - p'}, \quad (\text{C3})$$

where in the second equality we have used the property that $f_0(p' + i\omega_n) = f_0(p')$. After analytically continuing to real frequencies $i\omega_n \rightarrow \omega - i\delta$, the phonon linewidth can be obtained

$$\Gamma_{\mathbf{q}}^{\text{e-ph}} \equiv 2\text{Im} \{ \Sigma(\mathbf{q}, \omega_{\mathbf{q}} - i\delta) \} = (2\pi) \int_{\mathbf{p}} (g_{\mathbf{p}', \mathbf{p}}^{\mathbf{q}})^2 |\langle +\mathbf{p} | +\mathbf{p}' \rangle|^2 [f_0(p) - f_0(p')] \delta(p' - p - \omega_{\mathbf{q}}), \quad (\text{C4})$$

where we have used the Cauchy-Dirac relation $\frac{1}{x-a-i\delta} = P \frac{1}{x-a} + i\pi\delta(x-a)$. Note that the structure factor is given by

$$|\langle +\mathbf{p} | +\mathbf{p}' \rangle|^2 = \frac{1 + \hat{\mathbf{d}}(\mathbf{p}) \cdot \hat{\mathbf{d}}(\mathbf{p}')}{2}. \quad (\text{C5})$$

We will also use the approximation where

$$f_0(p) - f_0(p') \approx \omega_{\mathbf{q}} [-f_0'(p)] \approx \omega_{\mathbf{q}} \delta(p - p_f), \quad (\text{C6})$$

where the first equality comes from $p, p' \sim p_f \gg cq$ and the latter is the lowest order in the Sommerfeld approximation. The intranode contribution is given by the loop with fermions of the same chirality. After a simple calculation, it can be shown that

$$\Gamma_{\text{e-ph}}^{\text{intra}}(\mathbf{q}) = \begin{cases} 2 \cdot \frac{C}{4\pi} q p_f^2 \left(1 - \frac{q^2}{4p_f^2} \right), & \text{if } q \leq 2p_f, \\ 0, & \text{if } q > 2p_f. \end{cases} \quad (\text{C7})$$

The leading factor of 2 comes from considering both L intraband and R intraband contributions, which are identical. The interband contribution on the other hand can be shown to be

$$\Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q}) = \begin{cases} \frac{C}{4\pi} \frac{q^2}{|\mathbf{q}-2\mathbf{b}|} p_f^2 \left[1 - \frac{|\mathbf{q}-2\mathbf{b}|^2}{4p_f^2} + \frac{|\mathbf{q}-2\mathbf{b}|^2}{2p_f^2} \cos^2 \theta_{b, q-2b} - \left(1 - \frac{|\mathbf{q}-2\mathbf{b}|^2}{4p_f^2} \right) \frac{\sin^2 \theta_{b, q-2b}}{2} \right], & \text{if } |\mathbf{q} - 2\mathbf{b}| \leq 2p_f, \\ 0, & \text{if } |\mathbf{q} - 2\mathbf{b}| > 2p_f. \end{cases} \quad (\text{C8})$$

The calculation of these linewidths is similar to the calculation of the collision matrix terms for phonon absorption and emission by fermions provided in the next section, so we refer the reader to it for more detail. The full linewidth is simply given by

$$\Gamma_{\mathbf{q}}^{\text{e-ph}} = \Gamma_{\text{e-ph}}^{\text{intra}}(\mathbf{q}) + \Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q}). \quad (\text{C9})$$

Appendix D: Electron-Phonon Coupling

The electron-phonon coupling strength is usually parameterized [29] in terms of the dimensionless

$$\lambda = \frac{1}{\pi \int_{\mathbf{p}} \delta(\varepsilon_{\mathbf{p}} - \mu)} \int_{\mathbf{q}} \frac{\Gamma_{\mathbf{q}}^{\text{e-ph}}}{\omega_{\mathbf{q}}^2}, \quad (\text{D1})$$

where $g(p_f) = 2p_f^2/(2\pi^2)$ is the electronic density of states at the Fermi level. The integral can be evaluated using the phonon linewidths for intraband (C7) and interband scattering (C8) using (C9). This in turn gives

$$\lambda = \frac{1}{\pi \int_{\mathbf{p}} \delta(\varepsilon_{\mathbf{p}} - \mu)} \frac{20Cp_f^4}{3c^2} = \frac{5Cp_f^2}{6\pi^2 c^2} \Rightarrow Cp_f^2 = \frac{6\pi^2}{5} \lambda c^2 \sim 12\lambda c^2. \quad (\text{D2})$$

Using $\lambda \sim 0.1 - 1.5$ [30] and $c \sim 0.02$, one may expect $Cp_f^2 \sim 0.01$.

Appendix E: Phonon Absorption/Emission

The collision integral pertaining to phonon absorption or emission by fermionic excitations is given by

$$\begin{aligned} \mathcal{I}_{\text{e-ph}}[f_{\lambda}](\mathbf{p}) &= \sum_{\lambda'} \int_{\mathbf{q}, \mathbf{p}'} |M_{\text{abs}}^{\lambda\lambda'}|^2(\mathbf{p}, \mathbf{q}, \mathbf{p}') (2\pi)^4 \delta^{(4)}(p + q - p') \{f_{\lambda}(\mathbf{p})b(\mathbf{q})[1 - f_{\lambda'}(\mathbf{p}')] - f_{\lambda'}(\mathbf{p}')][1 - f_{\lambda}(\mathbf{p})][1 + b(\mathbf{q})]\} \\ &+ \int_{\mathbf{q}, \mathbf{p}'} |M_{\text{emi}}^{\lambda\lambda'}|^2(\mathbf{p}, \mathbf{q}, \mathbf{p}') (2\pi)^4 \delta^{(4)}(p - q - p') \{f_{\lambda}(\mathbf{p})[1 + b(\mathbf{q})][1 - f_{\lambda'}(\mathbf{p}')] - b(\mathbf{q})f_{\lambda'}(\mathbf{p}')][1 - f_{\lambda}(\mathbf{p})]\}, \quad (\text{E1}) \end{aligned}$$

where λ and λ' refer to the chirality, L or R . After linearizing, removing the external field dependence and setting $f_L = f_R$ as in the main text, the corresponding operator $\mathcal{C}_{\text{e-ph}}\mathcal{X}$ appearing in the operator $\mathcal{C}\mathcal{X}$ of equation (14) can be shown to be

$$\begin{aligned} f_0(\mathbf{p})[1 - f_0(\mathbf{p})]\mathcal{C}_{\text{e-ph}}\mathcal{X}(\mathbf{p}) &= \beta \sum_{\lambda'} \int_{\mathbf{q}, \mathbf{p}'} |M_{\text{abs}}^{L\lambda'}|^2(\mathbf{p}, \mathbf{q}, \mathbf{p}') (2\pi)^4 \delta^{(4)}(p + q - p') f_0(p) b_0(cq) [1 - f_0(p')] [\mathcal{X}(\mathbf{p}) - \mathcal{X}(\mathbf{p}')] \\ &+ \int_{\mathbf{q}, \mathbf{p}'} |M_{\text{emi}}^{L\lambda'}|^2(\mathbf{p}, \mathbf{q}, \mathbf{p}') (2\pi)^4 \delta^{(4)}(p - q - p') f_0(p) [1 + b_0(cq)] [1 - f_0(p')] [\mathcal{X}(\mathbf{p}) - \mathcal{X}(\mathbf{p}')]. \quad (\text{E2}) \end{aligned}$$

Introducing the inner product (20), the corresponding collision term in the variational functional (21) can be expressed as

$$(\mathcal{X}, \mathcal{C}_{\text{e-ph}}\mathcal{X}) = \frac{1}{2} \cdot 2\beta^2 \sum_{\lambda'} \int_{\mathbf{p}, \mathbf{q}, \mathbf{p}'} |M_{\text{abs}}^{L\lambda'}|^2(\mathbf{p}, \mathbf{q}, \mathbf{p}') (2\pi)^4 \delta^{(4)}(p + q - p') f_0(p) b_0(cq) [1 - f_0(p')] [\mathcal{X}(\mathbf{p}) - \mathcal{X}(\mathbf{p}')]^2. \quad (\text{E3})$$

The factor of 1/2 comes from the multiplicity of the function $\mathcal{X}(\mathbf{p})$ inside the integral and the factor of 2 is due to the emission term being the same as the absorption one under the exchange of the integration variables $\mathbf{p} \leftrightarrow \mathbf{p}'$. We now turn to considering each individual component of $|M_{\text{abs}}^{L\lambda'}|^2(\mathbf{p}, \mathbf{q}, \mathbf{p}')$.

1. Intranode Absorption/Emission

In this case, the square of the scattering amplitude has the form (A13). To solve the integral, we undertake the following steps:

- The \mathbf{p}' integration is removed through the momentum delta.

- The energy conservation delta is rewritten as

$$\delta(p + cq - p') = \frac{p'}{pq} \delta(\cos \theta_{pq} - \cos \theta_0) \quad \text{where} \quad \cos \theta_0 \equiv \frac{q}{2p} (c^2 - 1) + c. \quad (\text{E4})$$

Since $c \ll 1$, this effectively restricts the q integration range to values below $2p$.

- Using conservation of momentum, it can be shown that

$$\cos \theta_{pp'} = \frac{p}{p'} + \frac{q}{p'} \cos \theta_{pq} = 1 + \frac{q^2}{2pp'} (c^2 - 1), \quad (\text{E5})$$

where the restriction from (E4) has been used in the second equality.

- The equilibrium distribution functions are rearranged:

$$b_0(cq)[1 - f_0(p')] = [1 - f_0(p)][b_0(cq) + f_0(p')]. \quad (\text{E6})$$

- Exploiting that $cq \ll p, p' \sim p_f$, the scattering amplitude for the process is approximated to

$$|M_{\text{abs}}^{LL}|^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') \approx \frac{Cq}{2c} \left(1 - \frac{q^2}{4p^2}\right). \quad (\text{E7})$$

- Since in the end we use the finite basis (28) to solve the Boltzmann equation, we will need to calculate the components $(\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)$ with $i, j = 0, 1$. To do so, we need $|\Delta \mathcal{X}|_{ij}^2 \equiv [\mathcal{X}_i(\mathbf{p}) - \mathcal{X}_i(\mathbf{p}')][\mathcal{X}_j(\mathbf{p}) - \mathcal{X}_j(\mathbf{p}')]^2$ for each component:

$$|\Delta \mathcal{X}|_{00}^2 = \beta^2 (\mathbf{p} - \mathbf{p}')^2 = \beta^2 q^2, \quad (\text{E8})$$

$$|\Delta \mathcal{X}|_{11}^2 = 2[1 - \cos \theta_{pp'}] = \frac{q^2}{pp'} [1 - c^2], \quad (\text{E9})$$

$$|\Delta \mathcal{X}|_{01}^2 = |\Delta \mathcal{X}|_{10}^2 = \beta(p + p')[1 - \cos \theta_{pp'}] = \beta(p + p') \frac{q^2}{2pp'} [1 - c^2]. \quad (\text{E10})$$

Hence, the collision terms are

$$(\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j) = \frac{C}{2c} 2(2\pi)^2 \frac{1}{(2\pi)^5} \beta^2 \int_0^\infty p^2 dp f_0(p) [1 - f_0(p)] \int_0^{2p} q^2 dq \cdot q \left(1 - \frac{q^2}{4p^2}\right) \frac{p'}{pq} [b_0(cq) + f_0(p')] |\Delta \mathcal{X}|_{ij}^2. \quad (\text{E11})$$

The result fundamentally depends on the q integral, which can be solved in two different asymptotic regimes, depending on $\beta cq \sim T_{\text{BG}}/T$.

a. High Temperatures

In this case $\beta T_{\text{BG}} \ll 1$, which implies that for most of the integration region, $\beta cq \ll 1$. Therefore the Bose-Einstein distribution function can be approximated as $b_0(cq) \approx \frac{1}{\beta cq}$ and $f_0(p')$ can be disregarded as it is nonsingular in the small cq limit. One then can show that

$$\int_0^{2p} q^4 dq \cdot q \left(1 - \frac{q^2}{4p^2}\right) \frac{p'}{pq} [b_0(cq) + f_0(p')] \approx \beta^{-1} c^{-1} \frac{(2p)^4}{12}, \quad (\text{E12})$$

where we have taken $p' \approx p$. Therefore

$$\begin{aligned} (\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)_{\text{h.t.}}^{\text{intra}} &= \frac{2^4}{12} \frac{C}{2c^2} 2(2\pi)^2 \frac{1}{(2\pi)^5} \beta \int_0^\infty p^2 dp f_0(p) [1 - f_0(p)] \beta^{2-i-j} p^{4-i-j} \\ &= \frac{4C}{3(2\pi)^3 c^2} \beta^{2-i-j} p_f^{6-i-j} \left[1 + r^{-2} c_2 \binom{6-i-j}{2} + O(r^{-4})\right], \end{aligned} \quad (\text{E13})$$

where we have expanded up to next-to leading order in the Sommerfeld expansion using the parameter $r \equiv \beta p_f$.

b. *Low temperatures*

In this case $\beta T_{\text{BG}} \gg 1$, which now implies that the upper limit of integration for the q integral can be taken to infinity. It also means that the $\frac{q^2}{4p^2}$ term from the square of the scattering amplitude can be neglected. In this case, one cannot simply take the lowest order term in c , since now terms of the form $p' - p = cq$ can dominate over appearances of the scale T . Nevertheless, this can only happen in sums/subtractions of p and p' , so terms like p/p' can still be take to be ≈ 1 . The integration of q in this case is then seen to be

$$\int_0^{2p} q^4 dq \cdot q \left(1 - \frac{q^2}{4p^2}\right) \frac{p'}{pq} [b_0(cq) + f_0(p')] \approx \beta^{-5} c^{-5} \cdot 24 \left[\zeta(5) - \text{Li}_5 \left(-e^{-\beta(p-p_f)} \right) \right]. \quad (\text{E14})$$

Now one has that

$$\begin{aligned} (\mathcal{X}_i, C_{\text{e-ph}} \mathcal{X}_j)_{\text{l.t.}}^{\text{intra}} &= 24 \frac{C}{2c^6} 2(2\pi)^2 \frac{1}{(2\pi)^5} \beta^{-3} \int_0^\infty p^2 dp f_0(p) [1 - f_0(p)] \left[\zeta(5) - \text{Li}_5 \left(-e^{-\beta(p-p_f)} \right) \right] [1 - c^2]^{ij} \beta^{2-i-j} p^{-i-j} \\ &= \frac{24Cg_5}{(2\pi)^3 c^6} [1 - c^2]^{ij} \beta^{-2-i-j} p_f^{2-i-j}, \end{aligned} \quad (\text{E15})$$

where $g_5 \approx 5.2$ is defined in (B3).

2. Internode Absorption/Emission

Now the momentum conservation delta is given by $\delta^{(3)}(\mathbf{p} + \mathbf{q} - \mathbf{p}' - 2\mathbf{b})$. We take similar steps as the intranode case:

- The p' integration is removed through the momentum delta.
- The energy conservation delta is rewritten as

$$\delta(p + cq - p') = \frac{p'}{pQ} \delta(\cos \theta_{pQ} - \cos \theta_0) \quad \text{where} \quad \cos \theta_0 \equiv \frac{c^2 q^2 - 2cpq - Q^2}{2pQ}, \quad (\text{E16})$$

where $\mathbf{Q} \equiv \mathbf{q} - 2\mathbf{b}$. Similarly to before, this delta imposes the restriction $Q \leq 2p + cq \approx 2p$. However, the restriction

$$cq \leq Q, \quad (\text{E17})$$

must also be satisfied, which for large internodal separations is effectively $4cb \ll 2p_f$. For extremely large internodal separations this could pose an issue but we disregard such scenarios, effectively expecting that $c \ll p_f/b$.

- We perform the convenient change of variable $\cos \theta_{qb} \rightarrow Q$ by exploiting

$$\cos \theta_{qb} = \frac{q^2 + (2b)^2 - 2q(2b)}{2q(2b)}, \quad d \cos \theta_{qb} = -\frac{Q}{q(2b)}. \quad (\text{E18})$$

The lower limit of integration for Q is thus $|q - 2b|$ whereas the upper limit is given by $\min[q + 2b, 2p]$. Clearly the upper limit depends on the value of q , as $p \sim p_f$, hence it is convenient to translate this upper limit to the q integration. It translates into two regions:

1. $0 \leq q \leq \max[2p - 2b, 0]$ and $|q - 2b| \leq Q \leq q + 2b$.
2. $|2p - 2b| \leq q \leq 2p + 2b$ and $|q - 2b| \leq q \leq 2p$.

- Using conservation of momentum, it can be shown that

$$\cos \theta_{pp'} = \frac{p}{p'} + \frac{Q}{p'} \cos \theta_{pQ} = 1 + \frac{1}{2pp'} (c^2 q^2 - Q^2), \quad (\text{E19})$$

where the restriction from (E16) has been used in the second equality.

- The equilibrium distribution functions are rearranged:

$$b_0(cq)[1 - f_0(p')] = [1 - f_0(p)][b_0(cq) + f_0(p')]. \quad (\text{E20})$$

- The cosines with respect to the internodal distance can be reexpressed as

$$\cos \theta_{pb} \cos \theta_{p'b} = \frac{Q}{p'} \cos \theta_{pb} \cos \theta_{Qb} + \frac{p}{p'} \cos^2 \theta_{pb}. \quad (\text{E21})$$

Then, using that

$$\cos \theta_{pb} = \cos \theta_{pQ} \cos \theta_{Qb} + \sin \theta_{pQ} \sin \theta_{Qb} \cos \varphi_{Q,pb} \quad \text{and} \quad \cos \theta_{Qb} = \frac{q^2 - Q^2 - (2b)^2}{2Q(2b)}, \quad (\text{E22})$$

along with the restriction on $\cos \theta_{pQ}$ (E16) one can calculate the relevant azimuthal integral of the angular dependence in the square of the scattering amplitude (A14),

$$\int_0^{2\pi} d\varphi_{Q,pb} (1 + \cos \theta_{pp'} - 2 \cos \theta_{pb} \cos \theta_{p'b}) = 4\pi - \pi \sin^2 \theta_{Qb} \left(1 + \frac{3Q^2}{4p_f^2} \right), \quad (\text{E23})$$

where we have taken $p = p' = p_f$, which is effectively imposed by $f_0(p)[1 - f_0(p)]$ at leading order in the Sommerfeld expansion.

- Since in the end we use the finite basis (28) to solve the Boltzmann equation, we will need to calculate the components $(\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)$ with $i, j = 0, 1$. To do so, we need to calculate $|\Delta \mathcal{X}|_{ij}^2 \equiv [\mathcal{X}_i(\mathbf{p}) - \mathcal{X}_i(\mathbf{p}')][\mathcal{X}_j(\mathbf{p}) - \mathcal{X}_j(\mathbf{p}')]^2$ for each component:

$$|\Delta \mathcal{X}|_{00}^2 = \beta^2 (\mathbf{p} - \mathbf{p}')^2 = \beta^2 Q^2, \quad (\text{E24})$$

$$|\Delta \mathcal{X}|_{11}^2 = 2[1 - \cos \theta_{pp'}] = \frac{1}{pp'} [Q^2 - c^2 q^2], \quad (\text{E25})$$

$$|\Delta \mathcal{X}|_{01}^2 = |\Delta \mathcal{X}|_{10}^2 = \beta(p + p')[1 - \cos \theta_{pp'}] = \beta(p + p') \frac{1}{2pp'} [Q^2 - c^2 q^2]. \quad (\text{E26})$$

- Assuming the internodal separation is much larger than the Fermi radius $b \gg p_f$ implies that for temperatures below $T_{\text{BG,W}} = 2cb$, the integral is suppressed since phonons do not have enough energy to exchange fermions between the two nodes. Hence, only the high-temperature exchange is relevant, which as before, implies that we only need to keep the leading order in c , i.e. $p \approx p'$. Again, $f_0(p + cq)$ can be dropped since it is small in comparison to $b_0(cq) \approx (\beta cq)^{-1} \gg 1$.

The collision terms are then

$$\begin{aligned} (\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)^{\text{inter}} &= \frac{1}{2b} \frac{C}{4c} \frac{1}{(2\pi)^4} \beta^2 \int_0^\infty p^2 dp f_0(p) [1 - f_0(p)] \int_0^{2p-2b} q^2 dq [b_0(cq) + f_0(p + cq)] \int_{|q-2b|}^{q+2b} dQ \\ &\quad \left[4\pi - \pi \sin^2 \theta_{Qb} \left(1 + \frac{3Q^2}{4p_f^2} \right) \right] \frac{p'}{p} |\Delta \mathcal{X}|_{ij}^2 \\ &+ \frac{1}{2b} \frac{C}{4c} \frac{1}{(2\pi)^4} \beta^2 \int_0^\infty p^2 dp f_0(p) [1 - f_0(p)] \int_{|2p-2b|}^{2p+2b} q^2 dq [b_0(cq) + f_0(p + cq)] \int_{|q-2b|}^{2p} dQ \\ &\quad \left[4\pi - \pi \sin^2 \theta_{Qb} \left(1 + \frac{3Q^2}{4p_f^2} \right) \right] \frac{p'}{p} |\Delta \mathcal{X}|_{ij}^2. \end{aligned} \quad (\text{E27})$$

Notice how for $2b = 0$, only the first term in (E27) is non-zero, whereas for $2b > 2p$, only the second term is. Since effectively $p = p_f$, it makes sense thus to study the regimes $2b > 2p_f$ and $2b \leq 2p_f$ separately.

a. $2b > 2p_f$

The high temperature regime is defined by $\beta c q \ll 1$. This occurs for temperatures that satisfy $T \gg T_{\text{BG,W}} \sim c2b$. One can take $b_0(cq) \approx (\beta c q)^{-1}$ dominates over the $f_0(p+cq)$ term. In addition, all terms depending on cq in $|\Delta \mathcal{X}|_{ij}^2$ as they are smaller than all other energy scales, $p \sim p' \sim p_f$ and $p' - p \sim T$. Taking the leading order in the Sommerfeld expansion, the collision integral is

$$\begin{aligned} (\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)_{\text{h.t.}}^{\text{inter}} &= \frac{1}{2b} \frac{C}{4c^2} \frac{1}{(2\pi)^4} (\beta p_f)^{2-i-j} \int_{2b-2p_f}^{2p_f+2b} q dq \int_{|q-2b|}^{2p_f} Q^2 dQ \left[4\pi - \pi \sin^2 \theta_{Qb} \left(1 + \frac{3Q^2}{4p_f^2} \right) \right] \\ &= \frac{1}{2b} \frac{C}{4c^2} \frac{1}{(2\pi)^3} (\beta p_f)^{2-i-j} 8(2b)p_f^4 = \frac{2Cp_f^4}{c^2(2\pi)^3} (\beta p_f)^{2-i-j}. \end{aligned} \quad (\text{E28})$$

Notice how the result is indepent on the value of b .

On the other hand, for $\beta c q \ll 1$, which occurs when $T \ll T_{\text{BG,W}}$ temperatures, the q integral of the relevant term in (E27) is generically exponentially suppressed unless $2b$ is fairly close to $2p_f$. Hence, we take the contribution at $2b \geq 2p_f$ of this integral to be zero at low temperatures,

$$(\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)_{\text{l.t.}}^{\text{inter}} \approx 0. \quad (\text{E29})$$

b. $2b \leq 2p_f$

Now we need to consider both integrals in (E27). Since now $2p_f \geq 2b$, the transition temperature is now given by T_{BG} . Manipulating them in the same way as was done in the high temperature $2p_f < 2b$ case, one finds the same result,

$$\begin{aligned} (\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)_{\text{h.t.}}^{\text{inter}} &= \frac{1}{2b} \frac{C}{4c^2} \frac{1}{(2\pi)^4} (\beta p_f)^{2-i-j} \int_0^{2p_f-2b} q dq \int_{|q-2b|}^{q+2b} Q^2 dQ \left[4\pi - \pi \sin^2 \theta_{Qb} \left(1 + \frac{3Q^2}{4p_f^2} \right) \right] \\ + \frac{1}{2b} \frac{C}{4c^2} \frac{1}{(2\pi)^4} (\beta p_f)^{2-i-j} \int_{2p_f-2b}^{2p_f+2b} q dq \int_{|q-2b|}^{2p_f} Q^2 dQ \left[4\pi - \pi \sin^2 \theta_{Qb} \left(1 + \frac{3Q^2}{4p_f^2} \right) \right] &= \frac{2Cp_f^4}{c^2(2\pi)^3} (\beta p_f)^{2-i-j}. \end{aligned} \quad (\text{E30})$$

For low temperatures $T \ll T_{\text{BG}}$ we find that, as in the $b > 2p_f$ case, the the second integral in (E27) is exponentially suppressed unless $2b \rightarrow 2p_f$, a case we again do not consider. Hence we keep only the first integral. To make the problem tractable analytically, we note that in this regime the Bose-Einstein distribution forces $cq \sim T$. Since in this regime we expect $b, p_f \gg T/c \sim q$, we can keep the lowest order in q . Due to the limits of the Q integral, this implies that $Q \sim 2b$. This implies that $\cos \theta_{bQ} \approx 1$, meaning of course that $\sin \theta_{bQ} \approx 0$. Therefore, the collision integral in this regime is

$$\begin{aligned} (\mathcal{X}_i, \mathcal{C}_{\text{e-ph}} \mathcal{X}_j)_{\text{l.t.}}^{\text{inter}} &\approx 4\pi \frac{1}{2b} \frac{C}{4c} \frac{1}{(2\pi)^4} \beta^2 \int_0^\infty p^2 dp f_0(p) [1 - f_0(p)] \int_0^{2p-2b} q^2 dq [b_0(cq) + f_0(p+cq)] \int_{2b-q}^{q+2b} dQ |\Delta \mathcal{X}|_{ij}^2 \\ &\approx 4\pi \frac{1}{2b} \frac{C}{4c} \frac{1}{(2\pi)^4} \beta^2 \int_0^\infty p^2 dp f_0(p) [1 - f_0(p)] \int_0^{2p-2b} q^2 dq [b_0(cq) + f_0(p+cq)] 2q |\Delta \mathcal{X}|_{ij}^2 (Q = 2b) \\ &= \pi \frac{1}{2b} \frac{2C}{c^5} \frac{1}{(2\pi)^4} \beta^{-2-i-j} \int_0^\infty p^{2-i-j} dp f_0(p) [1 - f_0(p)] \\ &\quad \left\{ (2b)^2 6 \left[\zeta(4) - \text{Li}_4 \left(-e^{\beta(p-p_f)} \right) \right] - \delta^{i+j>0} \beta^{-2} 120 \left[\zeta(6) - \text{Li}_6 \left(-e^{-\beta(p-p_f)} \right) \right] \right\} \\ &= \pi \frac{1}{2b} \frac{2C}{c^5} \frac{1}{(2\pi)^4} \beta^{-2-i-j} p_f^{2-i-j} \left[6g_4(2b)^2 - 120g_6 \beta^{-2} \delta^{i+j>0} \right], \end{aligned} \quad (\text{E31})$$

where $\delta^{i+j>0}$ is vanishing for $i = j = 0$ and is equal to 1 otherwise, and g_n is a numeric constant defined in B3). Note that (E28) is suppressed by the small factor of c with respect to its intranode version (E15), so it can effectively be ignored.

Appendix F: Electron-Electron Collisions

The collision integral describing 2-body fermion collisions is given by

$$\begin{aligned} \mathcal{I}_{e-e}[f_a](\mathbf{p}) &= \frac{1}{2} \sum_{b,c,d} \int_{\mathbf{k},\mathbf{p}',\mathbf{k}'} |M_{cd}^{ab}|^2(\mathbf{p},\mathbf{k},\mathbf{p}',\mathbf{k}') (2\pi)^4 \delta^{(4)}(p+k-p'-k') \times \\ &\{f_a(\mathbf{p})f_b(\mathbf{k})[1-f_c(\mathbf{p}')] [1-f_d(\mathbf{k}')] - f_c(\mathbf{p}')f_d(\mathbf{k}') [1-f_a(\mathbf{p})] [1-f_b(\mathbf{k})]\}, \end{aligned} \quad (\text{F1})$$

where $a, b, c, d = L, R$ and the leading one half factor cancels the multiplicity of interband scattering from the sum and provides the correct symmetry factor for intraband scattering. Following the same procedure as in the collision integral for phonon emission/absorption of linearizing the distribution functions and introducing the inner product, the corresponding collision term in the variational functional (21) is

$$(\mathcal{X}, \mathcal{C}_{e-e} \mathcal{X}) = \frac{\beta^2}{8} \sum_{a,b,c,d} \int_{\mathbf{p},\mathbf{k},\mathbf{p}',\mathbf{k}'} |M_{cd}^{ab}|^2(\mathbf{p},\mathbf{k},\mathbf{p}',\mathbf{k}') (2\pi)^4 \delta^{(4)}(p+k-p'-k') f(p)f(k)[1-f(p')][1-f(k')] |\Delta\mathcal{X}|^2, \quad (\text{F2})$$

where $|\Delta\mathcal{X}|^2 \equiv |\mathcal{X}(\mathbf{p}) + \mathcal{X}(\mathbf{k}) - \mathcal{X}(\mathbf{p}') - \mathcal{X}(\mathbf{k}')|^2$ and the extra factor of 1/4 with respect to (F1) takes into account the multiplicity of the perturbation. As in the case of phonon emission/absorption, it is useful to consider intranode and internode scattering separately.

1. Intranode Scattering

Here we consider the case where the scattering is between left-handed fermions. For now we do not assume any particular behavior in any temperature regime, so the square of the scattering amplitude is $|M_{LL}^{LL}|^2 = |A_{LL,t}^{LL}|^2 + |A_{LL,u}^{LL}|^2 - 2\text{Re}\{A_{LL,t}^{LL*} A_{LL,u}^{LL}\}$. To deal with the collision integral, we perform the following manipulations:

- The \mathbf{k}' integration is removed through the momentum conservation delta.
- The integrals of the non-interference terms $|A_{LL,t}^{LL}|^2$ and $|A_{LL,u}^{LL}|^2$ are the same, as can be seen by performing a relabelling $\mathbf{p}' \leftrightarrow \mathbf{k}'$. Furthermore, we now perform a change of integration variables from the remaining outgoing electron momentum to the virtual phonon momentum, i.e. $\mathbf{p}' \rightarrow \mathbf{q} = \mathbf{p}' - \mathbf{p}$.
- Introduce the virtual phonon energy ω through

$$\begin{aligned} \delta(p+k-p'-k') &= \int_{-\infty}^{\infty} d\omega \delta(\omega - p' + p) \delta(\omega - k + k') \\ &= \int_{-q}^q d\omega \frac{p'}{pq} \delta\left(\frac{\omega}{q} + \frac{\omega^2 - q^2}{2pq} - \cos\theta_{pq}\right) \frac{k'}{kq} \delta\left(\frac{\omega}{q} - \frac{\omega^2 - q^2}{2kq} - \cos\theta_{kq}\right) \Theta\left(p - \frac{q - \omega}{2}\right) \Theta\left(k - \frac{q + \omega}{2}\right), \end{aligned} \quad (\text{F3})$$

where the integration limits on ω and the theta functions are needed to ensure the cosines have zeros for $|\cos\theta| \leq 1$.

- Employ the relation

$$\begin{aligned} f_0(p)[1-f_0(p+\omega)]f_0(k)[1-f_0(k-\omega)] &= b_0(\omega)[1+b_0(\omega)][f_0(p)-f_0(p+\omega)][-f_0(k)+f_0(k-\omega)] \\ &= (\beta\omega)^2 f_0(p)[1-f_0(p)]f_0(k)[1-f_0(k)] \end{aligned} \quad (\text{F4})$$

To make the problem more tractable analytically, we have taken the limit where $\omega \ll p_f$ in the last equality, which as we shall shortly see, is well justified.

These manipulations result in

$$\begin{aligned} (\mathcal{X}, \mathcal{C}_{e-e} \mathcal{X})^{\text{intra}} &= \frac{2}{(2\pi)^6} \frac{\beta^2}{8} \int_0^{k_D} dq \int_{-q}^q d\omega \int_0^{2\pi} d\varphi_{q,pk} \int_{\frac{q-\omega}{2}}^{\infty} pdp \int_{\frac{q+\omega}{2}}^{\infty} kdk \\ &|M_{LL}^{LL}|^2 (\beta\omega)^2 b_0(\omega)[1+b_0(\omega)]f_0(p)[1-f_0(p)]f_0(k)[1-f_0(k)] |\Delta\mathcal{X}|^2, \end{aligned} \quad (\text{F5})$$

which is the same expression as the one given in (34). One can see that the non-interference terms will contain the integral

$$\int_{-q}^q d\omega \left| \frac{1}{\omega^2 - \omega_q^2 + i\omega_q \Gamma_q} \right|^2 b_0(\omega)[1 + b_0(\omega)] \cdot F(\omega) = \int_{-q}^q d\omega \frac{b_0(\omega)[1 + b_0(\omega)]}{[(\omega - cq)^2 + \frac{\Gamma^2}{4}][(\omega + cq)^2 + \frac{\Gamma^2}{4}]} \cdot F(\omega), \quad (\text{F6})$$

where $F(\omega)$ is some function of ω with no singularities on the complex plane. The other functions however, do contain singularities. The propagators provide four poles

$$\omega_{+,\pm} = \pm cq + i\frac{\Gamma}{4}, \quad \omega_{-,\pm} = \pm cq - i\frac{\Gamma}{4}, \quad (\text{F7})$$

whereas the Bose-Einstein distribution functions have poles at the Matsubara frequencies, i.e.

$$\omega_n = i(2n\pi)\beta^{-1}, \quad \forall n \in \mathbb{Z}. \quad (\text{F8})$$

A similar situation is found for the interference terms.

a. High Temperatures

At temperatures $T \gg c\langle q \rangle = T_{\text{BG}}$, the poles will satisfy the hierarchy $\omega_n \gg \omega_{\pm,\pm}$ for all values of n . Therefore, the integral (F6) can be performed by using a complex contour on the upper half of the complex plane that only encloses the propagator poles $\omega_{+,\pm}$. To do this, first perform a change of variables $\omega \rightarrow \omega/q$, to recover

$$I_\omega = \int_{-1}^1 \frac{f(x)}{[(x-c)^2 + \frac{\Gamma^2}{4q^2}][(x+c)^2 + \frac{\Gamma^2}{4q^2}]} dx, \quad (\text{F9})$$

given in (35). Note that $f(x)$ is the function that has absorbed all the non-propagator factors appearing in (F6) and is not to be confused with the Fermi-Dirac distribution. A contour can now be chosen such that

$$I_\omega = 2\pi i \sum_{z=z_{+,\pm}} \text{Res} \left[\frac{f(z)}{[(z-c)^2 + \frac{\Gamma^2}{4q^2}][(z+c)^2 + \frac{\Gamma^2}{4q^2}]}, z \right] - I_C, \quad (\text{F10})$$

where I_C is the integral over the path that closes the contour and $x_{+,\pm} \equiv \omega_{+,\pm}/q$. Since $c \ll 1$ and $\frac{\Gamma}{4q} \ll 1$, the closing path can be chosen such that the variable of integration $z \gg z_{+,\pm}$. Therefore, $I_C = O(x_{+,\pm}^0)$. To calculate the residues, one formally expands the function $f(x)$ around 0, i.e. $f(z) = f(0) + f'(0)z + \frac{1}{2}f''(0)z^2 + O(z^3)$. Keeping only the next-to-leading order in the small parameters $z_{+,\pm}$ implies that one needs the expansion of $f(z)$ up to the quadratic term, whose integral is of order $O(x_{+,\pm}^{-1})$. Thus, I_C is subleading and can be ignored, so that finally the expression in (36) is recovered, i.e.

$$I_\omega = \frac{\pi q}{\Gamma} \left[\frac{1}{c^2} f(0) + \frac{1}{2} f''(0) \right]. \quad (\text{F11})$$

The condition $x = \omega/q = 0$ imposed by the lowest order term in I_ω implies that $p = p'$ and $k = k'$. In this limit, one can show that

$$\begin{aligned} \mathcal{X}(\mathbf{p}) - \mathcal{X}(\mathbf{p}') &= \mathcal{X}(p)\hat{\mathbf{p}} - \mathcal{X}(p')\hat{\mathbf{p}}' = -\frac{\mathcal{X}(p)}{p}\mathbf{q}, \\ \mathcal{X}(\mathbf{k}) - \mathcal{X}(\mathbf{k}') &= \mathcal{X}(k)\hat{\mathbf{k}} - \mathcal{X}(k')\hat{\mathbf{k}}' = \frac{\mathcal{X}(k)}{k}\mathbf{q}, \end{aligned} \quad (\text{F12})$$

so the perturbation-dependent term becomes

$$|\Delta \mathcal{X}|^2 \Big|_{\omega=0} = q^2 [X(p) - X(k)]^2, \quad (\text{F13})$$

where $X(p) = \mathcal{X}(p)/p$. It is simple to see that at the lowest order in the Sommerfeld expansion, where $p = k = p_f$, this expression is vanishing. To calculate the leading order contribution, it is convenient expand around the Fermi momentum as is mentioned in the main text,

$$X(p) = X(p_f) + \delta_p X'(p_f) + O(\delta_p^2), \quad (\text{F14})$$

where $\delta_p \equiv p - p_f$. By taking this expansion we are implicitly assuming that $X'(p_f) \neq 0$. For this to happen, the perturbation should satisfy $\mathcal{X}(p) \propto (p - p_f)^n$ for $n > 1$. We do not expect this to occur since the source term in the Boltzmann equation is at most $\propto (p - p_f)^1$, in the case of a thermal gradient (16). Finally, it is simple to show that under this expansion

$$|\Delta\mathcal{X}|^2 \Big|_{\omega=0} = X'(p_f)^2 [\delta_p^2 + \delta_k^2 - 2\delta_p\delta_k] + O(\delta^3). \quad (\text{F15})$$

The fact that the leading order term in the c expansion in I_ω is vanishing in the Sommerfeld expansion explains why we retain the next-to-leading order term in the c expansion. It can be shown that this term, proportional to $f''(0)$ leads to a non-vanishing term at leading order in the Sommerfeld expansion, as the second derivative of the perturbation term in this case is

$$\begin{aligned} \frac{q^2}{2} \frac{d^2 |\Delta\mathcal{X}|^2}{d\omega^2} \Big|_{\substack{p=k=p_f \\ \omega=0}} &= 2q^2 p_f^2 \left[\chi'(p_f) - \frac{\chi(p_f)}{p_f} \right]^2 \left[1 + \frac{q^2}{4p_f^2} - \left(1 - \frac{q^2}{4p_f^2} \right) \cos \varphi_{q,pk} \right] \\ &= 2q^2 p_f^2 \left[\chi'(p_f) - \frac{\chi(p_f)}{p_f} \right]^2 \left[1 + \frac{q^2}{4p_f^2} \right] = 2q^2 p_f^2 \left[1 + \frac{q^2}{4p_f^2} \right] X'(p_f)^2, \end{aligned} \quad (\text{F16})$$

where values of $\cos \theta_{pq}$ and $\cos \theta_{kq}$ fixed by energy conservation (F 1 a) have been used to evaluate

$$\cos \theta_{pk} = \cos \theta_{pq} \cos \theta_{kq} + \sin \theta_{pq} \sin \theta_{kq} \cos \varphi_{q,pk}. \quad (\text{F17})$$

The second equality is obtained by noticing that the rest of the integral has no terms depending on $\cos \varphi_{q,pk}$, so its integration over $\varphi_{q,pk}$ is vanishing. No derivatives over ω need to be taken elsewhere to evaluate $f''(0)$, as $\Delta\mathcal{X}'$ is also vanishing in the $p = k = p' = k' = p_f$ limit. Hence, the rest of the integrand, including the square of the scattering amplitude, can be directly evaluated at $\omega = 0$. Then, at the end of the day one finds

$$\begin{aligned} (\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{h.t.}}^{\text{intra}} &= 2C^2 \cdot \frac{\pi}{c^2} \frac{2}{(2\pi)^5} \frac{\beta^2}{8} \int_0^{2p_f} dq \frac{q^4}{\Gamma(q)} \\ &\times \int_0^\infty dp f_0(p)[1 - f_0(p)] p^2 \left(1 - \frac{q^2}{4p^2} \right) \int_0^\infty dk f_0(k)[1 - f_0(k)] k^2 \left(1 - \frac{q^2}{4k^2} \right) \\ &\times X'(p_f)^2 \left[(\delta_p^2 + \delta_k^2 - 2\delta_p\delta_k) + 2c^2 p_f^2 \left(1 + \frac{q^2}{4p_f^2} \right) \right], \end{aligned} \quad (\text{F18})$$

where we have used that $\omega = 0$, momentum conservation and the fixed cosines from energy conservation (F 1 a) to show that

$$(1 + \cos \theta_{pp'}) = 2 \left(1 - \frac{q^2}{4p^2} \right), \quad (1 + \cos \theta_{kk'}) = 2 \left(1 - \frac{q^2}{4k^2} \right). \quad (\text{F19})$$

Now, evaluating the p and k integrals, the $\delta_p\delta_k$ as the rest of the integrand is even in δ_p and δ_k at leading order in the Sommerfeld expansion. The resulting integral is

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{h.t.}}^{\text{intra}} = X'(p_f)^2 (Cp_f)^2 \cdot \frac{\pi}{c^2} \frac{1}{(2\pi)^5} \int_0^{2p_f} dq \frac{q^4}{\Gamma(q)} \left(1 - \frac{q^2}{4p_f^2} \right)^2 \left[c_2 \beta^{-2} + c^2 p_f^2 \left(1 + \frac{q^2}{4p_f^2} \right) \right]. \quad (\text{F20})$$

Notice that choosing $2p_f \ll k_D$ implies that the second term in the square brackets is suppressed in the high temperature regime $\beta T_{\text{BG}} \sim \beta c p_f \ll 1$, which is in any case the regime where this expression is valid. Had we chosen $k_D \ll 2p_f$, then there would be a regime of temperatures $T_D \ll T \ll T_{\text{BG}}$ where the second term in (F20) would dominate. We only consider the $2p_f < k_D$, and we will hence drop this term.

To proceed now, an explicit value for $\Gamma(q)$ needs to be given. We choose

$$\Gamma(q) = \Gamma_{\text{e-ph}}(q) + \gamma, \quad (\text{F21})$$

where γ is some linewidth, representing some other channel through which phonons can decay, e.g. impurities, and the phonon linewidth $\Gamma_{\text{e-ph}}(q)$ from interactions with electrons is given by the intraband contribution (C7), although omitting for now the extra factor of two from considering both left and right contributions. Then,

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{h.t.}}^{\text{intra}} = X'(p_f)^2 (Cp_f^2) \cdot \frac{1}{c^2} \frac{(2p_f)^4}{(2\pi)^3} A(\tilde{\gamma}) c_2 \beta^{-2}, \quad (\text{F22})$$

where

$$\int_0^{2p_f} dq \frac{q^4 \left(1 - \frac{q^2}{4p_f^2}\right)^2}{\frac{Cp_f^2}{4\pi} q \left(1 - \frac{q^2}{4p_f^2}\right) + \gamma} = \frac{4\pi}{(Cp_f^2)} (2p_f)^4 \int_0^1 dx \frac{x^4(1-x^2)^2}{x(1-x^2) + \tilde{\gamma}} \equiv \frac{4\pi}{(Cp_f^2)} (2p_f)^4 A(\tilde{\gamma}), \quad (\text{F23})$$

and $\tilde{\gamma} = \frac{2\pi\gamma}{p_f(Cp_f^2)}$. In the case where the dominant phonon decay channel is given by the electron-phonon interaction, then $\tilde{\gamma} = 0$ and $A(0) = \frac{1}{12}$, hence

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{h.t.}}^{\text{intra}} = [X'(p_f)p_f^2]^2 (Cp_f^2) \frac{4c_2\beta^{-2}}{3(2\pi)^3 c^2} \quad (\text{F24})$$

i.e. the same expression as that of (37).

To finalize the discussion of intraband fermion scattering we now prove that the interference term in $|M_{LL}^{LL}|^2$ is subleading with respect to the non-interference terms. Fundamentally, the interference term $2\text{Re}\{A_t^* A_u\}$ includes the product of the t and u channel phonon propagators,

$$|M_{LL}^{LL}|_{\text{interference}}^2 \sim \left[\frac{q_t^2}{\omega_t^2 - \omega_{q_t}^2 + i\eta_t} \frac{q_u^2}{\omega_u^2 - \omega_{q_u}^2 - i\eta_u} + c.c. \right], \quad (\text{F25})$$

where $\omega_t = p' - p$, $\omega_u = k' - p$, $\mathbf{q}_t = \mathbf{p}' - \mathbf{p}$ and $\mathbf{q}_u = \mathbf{k}' - \mathbf{p}$ and the η include the phonon linewidth. To perform the corresponding collision integral (F2) of this term, we proceed with the following manipulations:

- Remove the \mathbf{k} integration through the momentum conservation delta. Then two changes of integration variables are performed, $\mathbf{p}' \rightarrow \mathbf{q}_t$ and $\mathbf{k}' \rightarrow \mathbf{q}_u$
- The energy conservation delta is now dealt with by introducing two dummy variables ω_t and ω_u :

$$\begin{aligned} \delta(p + k - p' - k') &= \int_{-\infty}^{\infty} d\omega_t \int_{-\infty}^{\infty} d\omega_u \delta(\omega_t - p' + p) \delta(\omega_u - k' + p) \delta(k - \omega_t - \omega_u - p) \\ &= \int_{-q_t}^{q_t} d\omega_t \int_{-q_u}^{q_u} d\omega_u \frac{p'}{pq_t} \delta\left(\frac{\omega}{q_t} + \frac{\omega_t^2 - q_t^2}{2pq_t} - \cos\theta_{pq_t}\right) \frac{k'}{pq_u} \delta\left(\frac{\omega_u}{q_u} + \frac{\omega_u^2 - q_u^2}{2pq_u} - \cos\theta_{pq_u}\right) \frac{k}{q_t q_u} \delta\left(\cos\theta_{q_t q_u} - \frac{\omega_t \omega_u}{q_t q_u}\right) \\ &\quad \Theta\left(p - \frac{q_t - \omega_t}{2}\right) \Theta\left(p - \frac{q_u - \omega_u}{2}\right). \end{aligned} \quad (\text{F26})$$

- The relevant angular integrations will be over $\cos\theta_{pq_t}$, $\cos\theta_{pq_u}$ and φ_{p,q_t,q_u} . The remaining cosine appearing in the deltas above can be expressed as a combination of the former variables, $\cos\theta_{q_t q_u} = \cos\theta_{pq_u} \cos\theta_{pq_t} + \sin\theta_{pq_u} \sin\theta_{pq_t} \cos\varphi_{p,q_t,q_u}$. Hence, the delta for $\cos\theta_{q_t q_u}$ is implicitly a delta for φ_{p,q_t,q_u} .
- The relevant poles will come from the integrals

$$\int_{-q_t}^{q_t} d\omega_t \int_{-q_u}^{q_u} d\omega_u \left[\frac{q_t^2}{\omega_t^2 - \omega_{q_t}^2 + i\eta_t} \frac{q_u^2}{\omega_u^2 - \omega_{q_u}^2 - i\eta_u} + c.c. \right] f(\omega_t, \omega_u, \dots). \quad (\text{F27})$$

Assuming the function $f(\omega_t, \omega_u, \dots)$ has no further poles near the small poles of the propagator, which is the case in the present regime $T \gg T_{\text{BG}}$, we can use the same contour procedure as in the case of the non-interference terms (F6). Expanding f as a power series of ω_t and ω_u around $\omega_t = \omega_u = 0$, one can show that this integral is proportional to a power of -2 of the small parameters c and η . Such a contribution is subleading with respect to the non-interference terms, where the small parameters appear as a power of -3 (F11), so it can be neglected.

b. Low temperatures

When $T \lesssim T_{\text{BG}}$, the Matsubara poles from the Bose-Einstein distribution function can no longer be left out of the contour of integration used to calculate (F6). As the temperature decreases, more and more Matsubara poles enter the contour, and in fact become smaller than the propagator poles $\sim cq \sim T_{\text{BG}}$. Therefore, we expect that these

poles will dominate the integral, which will translate to $\omega \sim T$ in the denominator of the phonon propagator. By the definition of this regime, $\omega^2 \sim T^2 \ll \omega_{\mathbf{q}}^2 \sim T_{\text{BG}}^2$, so we effectively take the phonon propagator (7) to be

$$\mathcal{D}(\mathbf{q}) \approx \frac{2\omega_{\mathbf{q}}}{-\omega_{\mathbf{q}}^2} + O\left(\frac{\omega}{\omega_{\mathbf{q}}}\right), \quad (\text{F28})$$

where we have also omitted the phonon linewidth, since it is no longer needed to find a finite solution. The form of (F28), along with the q factor coming from the phonon coupling (5) will make the scattering amplitudes A_t and A_u independent of the phonon momentum, \mathbf{q}_t and \mathbf{q}_u respectively. This facilitates the calculation of the square of the scattering amplitudes in this temperature regime (A10) and the computation of the collision integral itself (F5). Substituting (A10) into it, one obtains

$$\begin{aligned} (\boldsymbol{\chi}, \mathcal{C}_{e-e}\boldsymbol{\chi})_{\text{l.t.}}^{\text{intra}} &= \frac{C^2}{4c^4} \frac{2}{(2\pi)^6} \frac{\beta^2}{8} \int_0^{k_D} dq \int_{-q}^q d\omega (\beta\omega)^2 b_0(\omega) [1 + b_0(\omega)] \int_0^{2\pi} d\varphi_{q,pk} \\ &\times \int_{\frac{q-\omega}{2}}^{\infty} dp p^2 \int_{\frac{q+\omega}{2}}^{\infty} dk k^2 (1 - \cos \theta_{pk})^2 f_0(p) f_0(k) [1 - f_0(p)] [1 - f_0(k)] |\Delta\mathcal{X}|^2. \end{aligned} \quad (\text{F29})$$

Since $\omega \sim T \ll p, k \sim p_f$, we again expect that effectively $\omega = 0$ everywhere. However, as in the high temperature case, the perturbation term $|\Delta\mathcal{X}|^2$ vanishes at the lowest order in the Sommerfeld expansion, so we again need to consider the next-to leading order term in ω :

$$|\Delta\mathcal{X}|^2 = |\Delta\mathcal{X}|^2 \Big|_{\omega=0} + \frac{\omega^2}{2} \frac{d^2 |\Delta\mathcal{X}|^2}{d\omega^2} \Big|_{\substack{p=k=p_f \\ \omega=0}} + O(\omega^3). \quad (\text{F30})$$

As was mentioned in the high temperature calculation, the first derivative of $|\Delta\mathcal{X}|^2$ is vanishing when $p = k = p' = k' = p_f$, so the second derivative is needed. This results in

$$|\Delta\mathcal{X}|^2 = X'(p_f)^2 [q^2(\delta_p^2 + \delta_k^2 - 2\delta_p\delta_k) + 2\omega^2 p_f^2 (1 - \cos \theta_{pk})]. \quad (\text{F31})$$

Plugging it back into (F29), one can now simply carry out the ω , p and k integrations. For the $\varphi_{q,pk}$ integration, one can use (F17) and the restrictions on $\cos \theta_{pq}$ and $\cos \theta_{kq}$ (F 1 a) evaluated at $p = k = p_f$ and $\omega = 0$, i.e.

$$\cos \theta_{pk} = -\frac{q^2}{4p_f^2} + \left(1 - \frac{q^2}{4p_f^2}\right) \cos \varphi_{q,pk}, \quad (\text{F32})$$

to calculate the integrals

$$\int_0^{2\pi} d\varphi_{q,pk} (1 - \cos \theta_{pk})^2 = 2\pi \left(1 + \frac{q^2}{4p_f^2}\right)^2 + \pi \left(1 - \frac{q^2}{4p_f^2}\right)^2, \quad (\text{F33})$$

$$\int_0^{2\pi} d\varphi_{q,pk} (1 - \cos \theta_{pk})^3 = 2\pi \left(1 + \frac{q^2}{4p_f^2}\right)^3 + 3\pi \left(1 + \frac{q^2}{4p_f^2}\right) \left(1 - \frac{q^2}{4p_f^2}\right)^2. \quad (\text{F34})$$

One then obtains

$$\begin{aligned} (\boldsymbol{\chi}, \mathcal{C}_{e-e}\boldsymbol{\chi})_{\text{l.t.}}^{\text{intra}} &= [X'(p_f)^2 p_f^2]^2 \frac{C^2}{4c^4} \frac{2}{(2\pi)^6} \frac{\beta^{-3}}{8} \int_0^{2p_f} dq \\ &\left\{ 4c_2^2 q^2 \left[2\pi \left(1 + \frac{q^2}{4p_f^2}\right)^2 + \pi \left(1 - \frac{q^2}{4p_f^2}\right)^2 \right] + 2b_4 p_f^2 \left[2\pi \left(1 + \frac{q^2}{4p_f^2}\right)^3 + 3\pi \left(1 + \frac{q^2}{4p_f^2}\right) \left(1 - \frac{q^2}{4p_f^2}\right)^2 \right] \right\}. \end{aligned} \quad (\text{F35})$$

Finally, we use the following integrals

$$\int_0^{2p_f} dq q^2 \left[2\pi \left(1 + \frac{q^2}{4p_f^2}\right)^2 + \pi \left(1 - \frac{q^2}{4p_f^2}\right)^2 \right] = \frac{2^6 \pi}{35} (2p_f)^3, \quad (\text{F36})$$

$$\int_0^{2p_f} dq p_f^2 \left[2\pi \left(1 + \frac{q^2}{4p_f^2}\right)^3 + 3\pi \left(1 + \frac{q^2}{4p_f^2}\right) \left(1 - \frac{q^2}{4p_f^2}\right)^2 \right] = \frac{2^6 \pi}{35} (2p_f)^3, \quad (\text{F37})$$

to obtain

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t.}}^{\text{intra}} = [X'(p_f)^2 p_f^2]^2 \frac{C^2}{4c^4} \frac{2}{(2\pi)^6} \frac{\beta^{-3}}{8} \frac{2^6 \pi}{35} (2p_f)^3 [4c_2^2 + 2b_4] = [X'(p_f)^2 p_f^2]^2 \frac{2^4 C^2 p_f^3 \beta^{-3}}{35(2\pi)^5 c^4} [4c_2^2 + 2b_4], \quad (\text{F38})$$

which is the same expression as the one given in the main text (42).

2. Generic High Temperature Scattering

Instead of performing the calculation for high-temperature $T \gg T_{\text{BG}}$ specifically for electron-electron scattering between different Weyl nodes, we will provide a derivation for a generic system and show that a similar result to (F24) is found. In that discussion it was shown that interference terms are negligible in the regime where $c\mathbf{q} \ll T$. We can therefore write the generic collision term for a generic system with arbitrary band structure ignoring such interference terms,

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{h.t.}} = 2 \sum_{abcd} \frac{1}{8} \cdot (2\pi) \cdot \beta^2 \int_{\mathbf{q}, \mathbf{p}, \mathbf{k}} \int_{-\infty}^{\infty} d\omega \left| \frac{2\omega_{\mathbf{q}} g_{-\mathbf{q}}^{bk, dk'} * g_{\mathbf{q}}^{ap, cp'}}{\omega^2 - \omega_{\mathbf{q}}^2 + i\omega_{\mathbf{q}} \Gamma_{\mathbf{q}}} \right|^2 \times \delta(\omega - \varepsilon_{c\mathbf{p}'} + \varepsilon_{a\mathbf{p}}) \delta(\omega - \varepsilon_{b\mathbf{k}} + \varepsilon_{d\mathbf{k}'}) f_0(\varepsilon_{a\mathbf{p}}) f_0(\varepsilon_{b\mathbf{k}}) [1 - f_0(\varepsilon_{c\mathbf{p}'})] [1 - f_0(\varepsilon_{d\mathbf{k}'})] |\Delta\mathcal{X}|^2, \quad (\text{F39})$$

where a, b, c, d are the band indices and the leading factor of 2 takes into account the contributions of t and u channels. Using the ω -integral result (F11) in this regime, one obtains

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{h.t.}} = 2 \sum_{abcd} \frac{1}{8} \cdot (2\pi) \cdot \beta^2 \int_{\mathbf{q}} \frac{\pi 4\omega_{\mathbf{q}}^2}{\Gamma_{\mathbf{q}} \omega_{\mathbf{q}}^2} \int_{\mathbf{k}} |g_{-\mathbf{q}}^{bk, dk'}|^2 f_0(\varepsilon_{b\mathbf{k}}) [1 - f_0(\varepsilon_{b\mathbf{k}})] \delta(\varepsilon_{d\mathbf{k}'} - \varepsilon_{b\mathbf{k}}) \int_{\mathbf{p}} |g_{\mathbf{q}}^{ap, cp'}|^2 f_0(\varepsilon_{a\mathbf{p}}) [1 - f_0(\varepsilon_{a\mathbf{p}})] \delta(\varepsilon_{c\mathbf{p}'} - \varepsilon_{a\mathbf{p}}) |\Delta\mathcal{X}|^2. \quad (\text{F40})$$

a. Thermal Conductivity

The perturbation term for $\omega = 0$ is of the form

$$|\Delta\mathcal{X}|^2 = |\mathcal{X}_a(\varepsilon_{a\mathbf{p}}, \hat{\mathbf{p}}) - \mathcal{X}_c(\varepsilon_{a\mathbf{p}}, \hat{\mathbf{p}}')|^2 + |\mathcal{X}_b(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}) - \mathcal{X}_d(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}')|^2 + 2(\mathcal{X}_a(\varepsilon_{a\mathbf{p}}, \hat{\mathbf{p}}) - \mathcal{X}_c(\varepsilon_{a\mathbf{p}}, \hat{\mathbf{p}}')) \cdot (\mathcal{X}_b(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}) - \mathcal{X}_d(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}')). \quad (\text{F41})$$

For the thermal conductivity $\mathcal{X}_a(\varepsilon_{a\mathbf{p}}, \hat{\mathbf{p}}) \propto (\varepsilon_{a\mathbf{p}} - \mu)$. This implies that the squared terms are proportional to $(\varepsilon_{a\mathbf{p}} - \mu)^2$ and $(\varepsilon_{b\mathbf{k}} - \mu)^2$, whereas the cross-term is proportional to $(\varepsilon_{a\mathbf{p}} - \mu)(\varepsilon_{b\mathbf{k}} - \mu)$. Since the latter is clearly odd in both the $(\varepsilon_{a\mathbf{p}} - \mu)$ and $(\varepsilon_{b\mathbf{k}} - \mu)$ whereas the rest of the integrand is even at the lowest order in those variables, making the integral over $\varepsilon_{a\mathbf{p}} - \mu$ and $\varepsilon_{b\mathbf{p}} - \mu$ (obtained from a change of variables with the p and k variables as usual) vanish. Therefore, effectively one has

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{h.t.}} = 4 \sum_{abcd} \frac{1}{8} \cdot (2\pi) \cdot \beta^2 \int_{\mathbf{q}} \frac{\pi 4\omega_{\mathbf{q}}^2}{\Gamma_{\mathbf{q}} \omega_{\mathbf{q}}^2} \int_{\mathbf{k}} |g_{-\mathbf{q}}^{bk, dk'}|^2 f_0(\varepsilon_{b\mathbf{k}}) [1 - f_0(\varepsilon_{b\mathbf{k}})] \delta(\varepsilon_{d\mathbf{k}'} - \varepsilon_{b\mathbf{k}}) |\mathcal{X}_b(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}) - \mathcal{X}_d(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}')|^2 \int_{\mathbf{p}} |g_{\mathbf{q}}^{ap, cp'}|^2 f_0(\varepsilon_{a\mathbf{p}}) [1 - f_0(\varepsilon_{a\mathbf{p}})] \delta(\varepsilon_{c\mathbf{p}'} - \varepsilon_{a\mathbf{p}}) = \sum_{bd} (2\pi) \cdot \beta^2 \int_{\mathbf{q}} \frac{1}{\beta\omega_{\mathbf{q}}} \int_{\mathbf{k}} |g_{-\mathbf{q}}^{bk, dk'}|^2 f_0(\varepsilon_{b\mathbf{k}}) [1 - f_0(\varepsilon_{b\mathbf{k}})] \delta(\varepsilon_{d\mathbf{k}'} - \varepsilon_{b\mathbf{k}}) |\mathcal{X}_b(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}) - \mathcal{X}_d(\varepsilon_{b\mathbf{k}}, \hat{\mathbf{k}}')|^2 = (\mathcal{X}, \mathcal{C}_{e-ph}\mathcal{X})_{\text{h.t.}}, \quad (\text{F42})$$

where in the latter two equalities we have employed

$$\Gamma_{\mathbf{q}} = \sum_{ab} (2\pi) \beta \omega_{\mathbf{q}} \int_{\mathbf{p}} |g_{\mathbf{q}}^{ap, bp'}|^2 f_0(\varepsilon_{a\mathbf{p}}) [1 - f_0(\varepsilon_{a\mathbf{p}})] \delta(\varepsilon_{b\mathbf{p}'} - \varepsilon_{a\mathbf{p}}), \quad (\text{F43})$$

$$(\mathcal{X}, \mathcal{C}_{e\text{-ph}}\mathcal{X})_{\text{h.t.}} = \sum_{ab} (2\pi) \cdot \beta^2 \int_{\mathbf{q}, \mathbf{p}} \frac{1}{\beta\omega_{\mathbf{q}}} |g_{\mathbf{q}}^{a\mathbf{p}, b\mathbf{p}'}|^2 f_0(\varepsilon_{a\mathbf{p}}) [1 - f_0(\varepsilon_{a\mathbf{p}})] \delta(\varepsilon_{b\mathbf{p}'} - \varepsilon_{b\mathbf{p}}) |\mathcal{X}_a(\varepsilon_{a\mathbf{p}}, \hat{\mathbf{p}}) - \mathcal{X}_b(\varepsilon_{a\mathbf{p}}, \hat{\mathbf{p}}')|^2. \quad (\text{F44})$$

These expressions are just the generalizations of (C4) and (E3). Note that at high temperatures $b_0(\omega_{\mathbf{q}}) \approx \frac{1}{\beta\omega_{\mathbf{q}}}$.

As mentioned before, this derivation fundamentally requires that $c\mathbf{q} \ll T$. If we return to our particular model with two Weyl nodes (2), this means that the temperature must be larger than the largest possible phonon energy, which in the case where $b \gg p_f$ is equivalent to $T > T_{\text{BG}, \text{W}} \approx 2cb$. In the intermediate regime where $2cp_f \ll T \ll 2cb$, emission and absorption of phonons between different nodes is exponentially suppressed. In the case of two-body scattering of the type $LR \rightarrow LR$, the t -channel, where different chiralities do not mix, remains unaffected, as $q_t \sim p_f$, whereas the u -channel, where $q_u \sim b$, recovers its low-temperature form, i.e. where the propagator is effectively independent of the phonon frequency and the virtual phonon is "off-shell". One can show that the terms in $|M_{LR}^{LR}|^2$ depending on the u -channel are suppressed in comparison with the square of the t -channel amplitude $|A_t|^2$, so that effectively in this regime $|M_{LR}^{LR}|^2 \approx |A_t|^2$.

b. Electric Conductivity

For the electric conductivity, we take the relevant mode (see main text) $\mathcal{X} \propto F^0(p) = \beta p$. For processes that do not violate chirality, one then has that $|\Delta\mathcal{X}|^2 = 0$. For processes that do violate it once, e.g. $LR \rightarrow LL$, then $|\Delta\mathcal{X}|^2 = \beta^2(2b)^2$. Processes that violate chirality twice, e.g. $LL \rightarrow RR$ will have $|\Delta\mathcal{X}|^2 = \beta^2(4b)^2$. Noting that $\Gamma^{LR}(\mathbf{q}) = \Gamma^{RL}(\mathbf{q}) = \Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q})$ and $\Gamma^{LL}(\mathbf{q}) = \Gamma^{RR}(\mathbf{q}) = \Gamma_{\text{e-ph}}^{\text{intra}}(\mathbf{q})$, one can show that

$$\begin{aligned} (\mathcal{X}, \mathcal{C}_{e\text{-e}}\mathcal{X})_{\text{h.t.}, \sigma} &= 2 \sum_{abcd} \frac{1}{8} \cdot (2\pi) \cdot \beta^2 \int_{\mathbf{q}} \frac{\pi 4\omega_{\mathbf{q}}^2}{\Gamma_{\mathbf{q}}\omega_{\mathbf{q}}^2} \int_{\mathbf{k}} |g_{-\mathbf{q}}^{b\mathbf{k}, d\mathbf{k}'}|^2 f_0(\varepsilon_{b\mathbf{k}}) [1 - f_0(\varepsilon_{b\mathbf{k}})] \delta(\varepsilon_{d\mathbf{k}'} - \varepsilon_{b\mathbf{k}}) \\ &\quad \cdot \beta^2 [(2b)^2 \delta_{a+c, b+d\pm 1} + (4b)^2 \delta_{a+c, b+d\pm 2}] \int_{\mathbf{p}} |g_{\mathbf{q}}^{a\mathbf{p}, c\mathbf{p}'}|^2 f_0(\varepsilon_{a\mathbf{p}}) [1 - f_0(\varepsilon_{a\mathbf{p}})] \delta(\varepsilon_{c\mathbf{p}'} - \varepsilon_{a\mathbf{p}}) \\ &= \frac{\beta^4}{2} \int_{\mathbf{q}} \frac{1}{(\beta\omega_{\mathbf{q}})^2} \frac{8(2b)^2 \Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q}) \Gamma_{\text{e-ph}}^{\text{intra}}(\mathbf{q}) + 2(4b)^2 \Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q}) \Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q})}{2\Gamma_{\text{e-ph}}^{\text{intra}}(\mathbf{q}) + 2\Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q})} = \frac{\beta^4 (4b)^2}{2} \int_{\mathbf{q}} \frac{\Gamma_{\text{e-ph}}^{\text{inter}}(\mathbf{q})}{(\beta\omega_{\mathbf{q}})^2} = \beta^2 (4b)^2 \frac{2Cp_f^4}{3(2\pi)^3 c^2}. \quad (\text{F45}) \end{aligned}$$

This result rests on the assumption that $c\mathbf{q} \ll T$ for all relevant \mathbf{q} in these processes. This is the case for $T \gg 2T_{\text{BG}, \text{W}}$, as then all chirality-violating processes satisfy this requirement. For processes with $T \ll 2T_{\text{BG}, \text{W}}$, then the result (F11) would no longer be valid for processes that violate chirality twice, e.g. $L, L \rightarrow R, R$. The integral for these processes would take the low-temperature form, which is $\propto (\beta p_f)^{-2}$ and is therefore suppressed with respect to the remaining high-temperature terms $\propto (\beta p_f)^{-1}$. The regime $T_{\text{BG}, \text{W}} \ll T \ll 2T_{\text{BG}, \text{W}}$ where the only processes that violate chirality once are allowed.

3. Chirality-conserving Internode Scattering at Low Temperatures

For temperatures below T_{BG} , intranode phonon absorption/emission also declines, although not exponentially, and all phonon propagators are effectively independent of ω so that (A12) is recovered for chirality conserving internode processes $LR \rightarrow LR$. The relevant collision integral is

$$(\mathcal{X}, \mathcal{C}_{e\text{-e}}\mathcal{X}) = \frac{\beta^2}{4} \int_{\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}'} |M_{LR}^{LR}|^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') (2\pi)^4 \delta^{(4)}(p + k - p' - k') f(p) f(k) [1 - f(p')] [1 - f(k')] |\Delta\mathcal{X}|^2, \quad (\text{F46})$$

where the scattering amplitude is now given by (A12). Note that while the momenta \mathbf{p} and \mathbf{p}' are in the reference frame of the L node and \mathbf{k} and \mathbf{k}' are in the reference frame of the R node, the internodal distance $2\mathbf{b}$ vector cancels out of the momentum conservation delta, so that the actual distance $2b$ makes no appearance in the integral. Only the direction is relevant, as it in the square of the scattering amplitude $|M_{LR}^{LR}|^2$. As in the previous integrals, integration is performed with respect to the vectors \mathbf{p} , \mathbf{k} and $\mathbf{q} \equiv \mathbf{p}' - \mathbf{p} = \mathbf{k} - \mathbf{k}'$. The relevant angular variables are $\cos\theta_{bq}$, $\cos\theta_{pq}$, $\cos\theta_{kq}$, $\varphi_{q, pb}$, and $\varphi_{q, kb}$. In terms of these variables, the anisotropic quantities appearing in can be expressed

as

$$(\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}}) = \left[-\frac{q}{2p_f} \cos \theta_{bq} + \sqrt{1 - \frac{q^2}{4p_f^2}} \sin \theta_{bq} \cos \varphi_{q,pb} \right] \left[\frac{q}{2p_f} \cos \theta_{bq} + \sqrt{1 - \frac{q^2}{4p_f^2}} \sin \theta_{bq} \cos \varphi_{q,kb} \right], \quad (\text{F47})$$

$$\begin{aligned} (\hat{\mathbf{p}}' \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}}' \cdot \hat{\mathbf{b}}) &= \left[q \cos \theta_{bq} + \hat{\mathbf{p}} \cdot \hat{\mathbf{b}} \right] \left[-q \cos \theta_{bq} + \hat{\mathbf{k}} \cdot \hat{\mathbf{b}} \right] \\ &= \left[\frac{q}{2p_f} \cos \theta_{bq} + \sqrt{1 - \frac{q^2}{4p_f^2}} \sin \theta_{bq} \cos \varphi_{q,pb} \right] \left[-\frac{q}{2p_f} \cos \theta_{bq} + \sqrt{1 - \frac{q^2}{4p_f^2}} \sin \theta_{bq} \cos \varphi_{q,kb} \right], \end{aligned} \quad (\text{F48})$$

where we have replaced $\cos \theta_{pq}$ and $\cos \theta_{kq}$ by the values imposed by energy conservation (F 1 a) at $p = k = p' = k' = p_f$. It is also convenient to calculate the following terms

$$(1 - \cos \theta_{pk})(\hat{\mathbf{p}}' \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}}' \cdot \hat{\mathbf{b}}) = -\frac{q^2}{4p_f^2} \left(1 + \frac{q^2}{4p_f^2} \right) \cos^2 \theta_{bq} - \left(1 - \frac{q^2}{4p_f^2} \right)^2 \sin^2 \theta_{bq} \cos^2 \varphi_{q,pb} \cos^2 \varphi_{q,kb}, \quad (\text{F49})$$

$$\begin{aligned} (1 - \cos^2 \theta_{pk})(\hat{\mathbf{p}}' \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}}' \cdot \hat{\mathbf{b}}) &= -\frac{q^2}{4p_f^2} \left[\left(1 + \frac{q^2}{4p_f^2} \right)^2 + \left(1 - \frac{q^2}{4p_f^2} \right)^2 (\cos^2 \varphi_{q,pb} \cos^2 \varphi_{q,kb} + \sin^2 \varphi_{q,pb} \sin^2 \varphi_{q,kb}) \right] \cos^2 \theta_{bq} \\ &\quad - 2 \left(1 + \frac{q^2}{4p_f^2} \right) \left(1 - \frac{q^2}{4p_f^2} \right)^2 \cos^2 \varphi_{q,pb} \cos^2 \varphi_{q,kb} \sin^2 \theta_{bq}, \end{aligned} \quad (\text{F50})$$

where we have omitted terms that vanish under the integration of the azimuthal angles $\varphi_{q,pb}$ and $\varphi_{q,kb}$. We have also made use of $\varphi_{q,pk} = \varphi_{q,pb} - \varphi_{q,kb}$, needed to expand $\cos \theta_{pk}$ (F32). The second term (F50) arises from the fact that the perturbation has the form

$$|\Delta \mathcal{X}|^2 = |\Delta \mathcal{X}|^2 \Big|_{\omega=0} + \frac{\omega^2}{2} \frac{d^2 |\Delta \mathcal{X}|^2}{d\omega^2} \Big|_{\substack{p=k=p_f \\ \omega=0}} = X'(p_f)^2 [q^2(\delta_p^2 + \delta_k^2 - 2\delta_p \delta_k) + 2\omega^2 p_f^2 (1 - \cos \theta_{pk})], \quad (\text{F51})$$

which includes a term dependent on $(1 - \cos \theta_{pk})$. Substituting in the value of $|M_{LR}^{LR}|^2$ given in (A12) into the collision integral term, one can see that the the angular integrals needed are

$$\begin{aligned} \mathcal{I}_0(q) &= \int_{-1}^1 d \cos \theta_{qb} \int_0^{2\pi} d\varphi_{q,pb} \int_0^{2\pi} d\varphi_{q,kb} \\ q^2 \left[(1 - \cos \theta_{pk})^2 + 2(1 - \cos \theta_{pk})(\hat{\mathbf{p}}' \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}}' \cdot \hat{\mathbf{b}}) + 2(1 - \cos \theta_{pk})(\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}}) + 4(\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{p}}' \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}}' \cdot \hat{\mathbf{b}}) \right], \end{aligned} \quad (\text{F52})$$

$$\begin{aligned} \mathcal{I}_1(q) &= p_f^2 \int_{-1}^1 d \cos \theta_{qb} \int_0^{2\pi} d\varphi_{q,pb} \int_0^{2\pi} d\varphi_{q,kb} \\ (1 - \cos \theta_{pk}) \left[(1 - \cos \theta_{pk})^2 + 2(1 - \cos \theta_{pk})(\hat{\mathbf{p}}' \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}}' \cdot \hat{\mathbf{b}}) + 2(1 - \cos \theta_{pk})(\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}}) + 4(\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{p}}' \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}}' \cdot \hat{\mathbf{b}}) \right]. \end{aligned} \quad (\text{F53})$$

After performing the integrals over p, k and ω , one recovers an analogous expression to that of (F35),

$$(\boldsymbol{\mathcal{X}}, \mathcal{C}_{e-e} \boldsymbol{\mathcal{X}})_{\text{l.t.}} = [X'(p_f)^2 p_f^2]^2 \frac{C^2}{4c^4} \frac{1}{(2\pi)^7} \frac{\beta^{-3}}{8} \int_0^{2p_f} dq [4c_2^2 \mathcal{I}_0 + 2b_4 \mathcal{I}_1]. \quad (\text{F54})$$

The integrals in q can be performed, resulting in

$$\int_0^{2p_f} dq \mathcal{I}_0(q) = \int_0^{2p_f} dq \mathcal{I}_1(q) = \frac{2^8 \cdot 11 \cdot 19\pi^2}{3^2 \cdot 5^2 \cdot 7} p_f^3. \quad (\text{F55})$$

Therefore,

$$(\boldsymbol{\mathcal{X}}, \mathcal{C}_{e-e} \boldsymbol{\mathcal{X}})_{\text{l.t.}} = [X'(p_f) p_f^2]^2 \frac{2 \cdot 11 \cdot 19 C^2 p_f^3 \beta^{-3}}{3^2 \cdot 5^2 \cdot 7 (2\pi)^5 c^4} [4c_2^2 + 2b_4]. \quad (\text{F56})$$

4. Chirality-violating Internode Scattering

a. Low Temperatures : Electric Conductivity

Unlike the 2-body processes considered up until now, processes where chirality is violated do expectedly depend on the magnitude of the internodal distance vector $2\mathbf{b}$. For instance, $LR \rightarrow LL$ processes are governed by the collision integral term

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t.}}^{LR,LL} = 4 \frac{\beta^2}{8} \int_{\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}'} |M_{LL}^{LR}|^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') (2\pi)^4 \delta(p+k-p'-k') \delta^{(3)}(\mathbf{p} + \mathbf{k} - \mathbf{p}' - \mathbf{k}' + 2\mathbf{b}) f(p)f(k)[1-f(p')][1-f(k')] |\Delta\mathcal{X}|^2. \quad (\text{F57})$$

The leading factor of 4 counts the multiplicity of the process. This integral resembles the one for Umklapp scattering with a crystal lattice vector $2\mathbf{b}$. Note however that this is purely formal, as in reality momentum is conserved, and the $2\mathbf{b}$ term is purely a consequence of the different reference frame for the incoming R Weyl fermion. The scattering amplitude is given by

$$\begin{aligned} |M_{LL}^{LR}|_{\text{l.t.}}^2 &= \frac{C^2}{4c^4} \left[1 - \hat{\mathbf{d}}(-\mathbf{b} + \mathbf{p}) \hat{\mathbf{d}}(\mathbf{b} + \mathbf{k}) \right] \left[1 - \hat{\mathbf{d}}(-\mathbf{b} + \mathbf{p}') \hat{\mathbf{d}}(-\mathbf{b} + \mathbf{k}') \right] \\ &= \frac{C^2}{4c^4} \left(1 - \cos\theta_{pk} + 2(\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}}) \right) (1 - \cos\theta_{p'k'}). \end{aligned} \quad (\text{F58})$$

Notice that since $\mathcal{X}(\mathbf{p}) \equiv \mathcal{X}(p)\mathbf{v}_p$, one can easily see that $\mathcal{X}(p) = F^0(p) \equiv \beta p$ is no longer a zero-mode of this integral due to the momentum conservation delta being Umklapp-like. As long as $\mathcal{X}(p)$ is non-vanishing at $p = p_f$, which is the case for the electrical conductivity, then the function $\mathcal{X}(p)$ chosen to represent the perturbation is not important, as they are all equivalent under the inner product (20). Since it is the relevant mode for the electric conductivity, we choose $\mathcal{X}(p) = F^0(p) = \beta p$.

To solve the collision integral (F 4 a), we follow a similar approach to the one given in [22]:

- As was done in the previous collision integrals, the \mathbf{k}' integration is removed through the momentum conservation delta introduce the dummy variable ω to separate the energy conservation delta, and perform the integral

$$\begin{aligned} \int_{-\infty}^{\infty} d\omega (\beta\omega)^2 b_0(\omega) [1 + b_0(\omega)] f_0(p) [1 - f_0(p)] f_0(k) [1 - f_0(k)] \delta(p' - p - \omega) \delta(k - k' - \omega) \\ \approx 2c_2 \beta^{-3} \delta(p - p_f) \delta(k - p_f) \delta(p' - p_f) \delta(k' - p_f). \end{aligned} \quad (\text{F59})$$

This result assumes ω is vanishing elsewhere in the integrand, which is a sound approximation since $\omega \sim T \ll p, k, p', k' \sim p_f$.

- For the chosen $\mathcal{X}(p) = F^0(p) = \beta p$, the perturbation term is easily seen to be, using the restrictions $p = k = p' = k'$ from (F59),

$$|\Delta\mathcal{X}|^2 = \beta^2 (\mathbf{p} + \mathbf{k} - \mathbf{p}' - \mathbf{k}')^2 = \beta^2 4b^2, \quad (\text{F60})$$

because of momentum conservation.

- The energy conservation delta corresponding to k' in (F59) can be dealt with by integrating $\hat{\mathbf{p}}'$ with respect to its angle with the vector

$$\mathbf{k} \equiv \mathbf{p} + \mathbf{k} + 2\mathbf{b}, \quad (\text{F61})$$

so that

$$\int_{\hat{\mathbf{p}}'} \delta(|\mathbf{p} + \mathbf{k} - \mathbf{p}' - \mathbf{g}| - p_f) = 2\pi \int_{-1}^1 d\cos\theta_{p'K} \frac{1}{K} \delta\left(\cos\theta_{p'K} - \frac{K}{2p_f}\right) = 2\pi \Theta(2p_f - K) \frac{1}{K}. \quad (\text{F62})$$

where the step function enforces that the cosine is between -1 and 1.

- Integrating over the remaining energy deltas in (F59), one finds

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t.,}\sigma}^{LR,LL} = p_f^6 \frac{2c_2}{(2\pi)^7} \beta^2 4b^2 \frac{\beta^{-1}}{2} \int_{\hat{\mathbf{p}}, \hat{\mathbf{k}}} |M_{LR}^{LR}|^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}') \Theta(2p_f - K) \frac{1}{K}. \quad (\text{F63})$$

- One can now perform a change of integration variables $\cos\theta_{pb}, \cos\theta_{kP} \rightarrow P, K$, where \mathbf{k} is defined as above and

$$\mathbf{p} \equiv \mathbf{k} - \mathbf{k} = \mathbf{p} + 2\mathbf{b}. \quad (\text{F64})$$

In doing so, the collision integral (F63) becomes

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t.}, \sigma}^{LR, LL} = \frac{p_f^4}{2b} \frac{2c_2}{(2\pi)^6} \beta^2 4b^2 \frac{\beta^{-1}}{2} \int_{|2b-p_f|}^{P_{\max}} dP \int_{|P-p_f|}^{K_{\max}} dK \int_0^{2\pi} d\varphi_{P, kb} |M_{LR}^{LR}|^2(\mathbf{p}, \mathbf{k}, \mathbf{p}', \mathbf{k}'), \quad (\text{F65})$$

where the upper integration limits, imposed by $\cos\theta_{pb} \leq 1$ and $\cos\theta_{kP} \leq 1$, as well as the kinematic restriction that $K \leq 2p_f$ (which also implies $P = |\mathbf{k} - \mathbf{k}| \leq 3p_f$), are

$$P_{\max} = \begin{cases} b + p_f & \text{if } b < 2p_f, \\ 3p_f & \text{if } b \geq 2p_f. \end{cases} \quad (\text{F66})$$

$$K_{\max} = \begin{cases} P + p_f & \text{if } P < p_f, \\ 2p_f & \text{if } P \geq p_f. \end{cases} \quad (\text{F67})$$

All that remains is to write the square of the scattering amplitude (F53) in terms of these integration variables. This can be done using

$$p_f^2 \cos\theta_{pk} = \cos\theta_{Pk} [Pp_f - 2bp_f \cos\theta_{Pb}] - 2bp_f \cos\varphi_{P, kb} \sin\theta_{Pk} \sin\theta_{Pb}, \quad (\text{F68})$$

$$\cos\theta_{pb} = \frac{P^2 - p_f^2 - (2b)^2}{2p_f(2b)}, \quad \cos\theta_{kb} = \cos\theta_{Pk} \cos\theta_{Pb} + \sin\theta_{Pk} \sin\theta_{Pb} \cos\varphi_{P, kb}, \quad (\text{F69})$$

$$\cos\theta_{Pk} = \frac{K^2 - P^2 - p_f^2}{2Pp_f}, \quad \cos\theta_{Pb} = \frac{(2b)^2 + P^2 - p_f^2}{2(2b)P}, \quad \cos\theta_{p'k'} = \frac{K^2 - 2p_f^2}{2p_f^2}. \quad (\text{F70})$$

so that the relevant azimuthal angle integrals for solving (F65) are

$$\int_0^{2\pi} d\varphi_{P, kb} (1 - \cos\theta_{pk})(1 - \cos\theta_{p'k'}) = (2\pi) \left(1 - \frac{K^2 - 2p_f^2}{2p_f^2}\right) \left[1 - \left(\frac{K^2 - P^2 - p_f^2}{4P^2 p_f^2}\right) (P^2 + p_f^2 - (2b)^2)\right], \quad (\text{F71})$$

$$\begin{aligned} & 2 \int_0^{2\pi} d\varphi_{P, kb} (\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}})(1 - \cos\theta_{p'k'}) \\ &= 2(2\pi) \left(1 - \frac{K^2 - 2p_f^2}{2p_f^2}\right) \left(\frac{p_f^2 + (2b)^2 - P^2}{2p_f(2b)}\right) \left(\frac{K^2 - P^2 - p_f^2}{2Pp_f}\right) \left(\frac{p_f^2 - (2b)^2 - P^2}{2(2b)P}\right). \end{aligned} \quad (\text{F72})$$

Finally, carrying out the K and P integrals results in

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t.}, \sigma}^{LR, LL} = \frac{C^2 p_f^4}{4c^4 2b} \frac{2c_2}{(2\pi)^6} \beta^2 4b^2 \frac{\beta^{-1}}{2} \cdot \begin{cases} 0 & \text{if } 2b > 4p_f, \\ \pi(4p_f - 2b)^3 \frac{(2b)^3 + 12(2b)^2 p_f + 96(2b)p_f^2 + 320p_f^3}{720p_f^4} & \text{if } 4p_f \geq 2b > 2p_f, \\ \pi(2b)^3 \frac{(2b)^5 - 320(2b)^2 p_f^3 - 2880(2b)p_f^4 + 9216p_f^5}{720p_f^4} & \text{if } 2p_f \geq 2b. \end{cases} \quad (\text{F73})$$

Considering now processes that violate chirality twice, such as $LL \rightarrow RR$, one would have a comparatively simpler scattering amplitude,

$$\begin{aligned} |M_{RR}^{LL}|_{\text{l.t.}}^2 &= \frac{C^4}{4c^4} \left[1 - \hat{\mathbf{d}}(-\mathbf{b} + \mathbf{p})\hat{\mathbf{d}}(-\mathbf{b} + \mathbf{k})\right] \left[1 - \hat{\mathbf{d}}(\mathbf{b} + \mathbf{p}')\hat{\mathbf{d}}(\mathbf{b} + \mathbf{k}')\right] \\ &= \frac{C^2}{4c^4} (1 - \cos\theta_{pk})(1 - \cos\theta_{p'k'}). \end{aligned} \quad (\text{F74})$$

The resulting integrals however are formally the same as (F4a) and (F65) with the replacement $2b \rightarrow 4b$, but the relevant integral with the azimuthal angle is just (F71), as the direction of \mathbf{b} no longer appears in the square of the scattering amplitude. The result is

$$(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t.}, \sigma}^{LL, RR} = \frac{C^2 p_f^4}{4c^4 4b} \frac{2c_2}{(2\pi)^6} \beta^2 16b^2 \frac{\beta^{-1}}{8} \cdot \begin{cases} 0 & \text{if } 2b > 4p_f, \\ \pi(4p_f - 4b)^4 \frac{(4b)^2 + 16(4b)p_f + 40p_f^2}{360p_f^4} & \text{if } 4p_f \geq 4b > 2p_f, \\ \pi(4b)^3 \frac{-3(4b)^5 + 360(4b)^3 p_f^2 - 640(4b)^2 p_f^3 - 2880(4b)p_f^4 + 6144p_f^5}{360p_f^4} & \text{if } 2p_f \geq 4b, \end{cases} \quad (\text{F75})$$

where we have taken into account that the multiplicity is now 1 instead of 4 as in the $L, R \rightarrow L, L$ process.

b. Low Temperatures: Thermal Conductivity

In the previous calculation we assumed that $\mathcal{X} \propto F^0(p) = \beta p$, since that is the relevant mode for the electric conductivity, as is shown in the main text. For the thermal conductivity κ however, one should consider $\mathcal{X} \propto \beta(p-p_f)$, so the result will be different. In fact, the perturbation now becomes similar to the low temperature perturbation term used for chirality-conserving processes (F30),

$$\begin{aligned} |\Delta\mathcal{X}|^2 &= |\Delta\mathcal{X}|^2 \Big|_{\omega=0} + \frac{\omega^2}{2} \frac{d^2|\Delta\mathcal{X}|^2}{d\omega^2} \Big|_{\substack{p=k=p_f \\ \omega=0}} + O(\omega^3) \\ &= X'(p_f)^2 \left[\delta_p^2 (\mathbf{p}' - \mathbf{p})^2 + \delta_k^2 (\mathbf{k} - \mathbf{k}')^2 + \omega^2 (\mathbf{k} - 2\mathbf{p}')^2 \right], \end{aligned} \quad (\text{F76})$$

where we have omitted odd terms in δ_p and δ_k , as they will vanish at lowest order in the Sommerfeld expansion. To deal with the terms that depend on the momenta, we note that at the lowest order in the Sommerfeld expansion, their moduli will satisfy $p = k = p' = k' = p_f$, so that

$$(\mathbf{p}' - \mathbf{p})^2 = 2p_f^2(1 - \cos\theta_{pp'}), \quad (\mathbf{k} - \mathbf{k}')^2 = 2p_f^2(1 - \cos\theta_{kk'}), \quad (\text{F77})$$

$$(\mathbf{k} - 2\mathbf{p}')^2 = K^2 + 4p_f^2 - 4Kp_f \cos\theta_{Kp'} = 4p_f^2 - K^2, \quad (\text{F78})$$

where in the latter we have used the restriction imposed by (F62). One can show that

$$\begin{aligned} 2 - \cos\theta_{pp'} - \cos\theta_{kk'} &= 1 + \frac{K^2}{2p_f^2} - \frac{P}{p_f} \cos\theta_{Pk} - 2\frac{P}{p_f} \cos\theta_{Pp'} + \frac{2b}{p_f} \cos\theta_{bp'} \\ &= 1 + \frac{K^2}{2p_f^2} - 2\frac{P}{p_f} \cos\theta_{Pk} - \frac{P^2}{p_f^2} + \frac{2bK}{2p_f^2} \cos\theta_{bK} + f(\varphi_{K,p'}), \end{aligned} \quad (\text{F79})$$

where $f(\varphi_{K,p'})$ is a function that is linear in cosines of azimuthal angles of \mathbf{p}' with respect to the pole \mathbf{k} , and will hence vanish under their integration. Therefore one has

$$|\Delta\mathcal{X}|^2 = X'(p_f)^2 \left[2\delta^2 p_f^2 \left(1 + \frac{K^2}{2p_f^2} - 2\frac{P}{p_f} \cos\theta_{Pk} - \frac{P^2}{p_f^2} + \frac{2bK}{2p_f^2} \cos\theta_{bK} \right) + \omega^2(4p_f^2 - K^2) \right], \quad (\text{F80})$$

where we have taken $\delta_p^2 = \delta_k^2 = \delta^2$, as once the integration of p and k is carried out, they will provide the same result. Hence, analogously to (F59), we find that

$$\begin{aligned} &\int_0^\infty dp \int_0^\infty dk \int_{-\infty}^\infty d\omega (\beta\omega)^2 b_0(\omega) [1 + b_0(\omega)] f_0(p) [1 - f_0(p)] f_0(k) [1 - f_0(k)] \delta(p' - p - \omega) \delta(k - k' - \omega) |\Delta\mathcal{X}|^2 \\ &\approx \beta^{-5} X'(p_f)^2 \left[4c_2^2 p_f^2 \left(1 + \frac{K^2}{2p_f^2} - 2\frac{P}{p_f} \cos\theta_{Pk} - \frac{P^2}{p_f^2} + \frac{2bK}{2p_f^2} \cos\theta_{bK} \right) + b_4(4p_f^2 - K^2) \right] \\ &= \beta^{-5} X'(p_f)^2 \left(2p_f^2 - \frac{K^2}{2} \right) [4c_2^2 + 2b_4] + \beta^{-5} X'(p_f)^2 \frac{2bK}{2} \cos\theta_{bK} 4c_2^2. \end{aligned} \quad (\text{F81})$$

Of course, elsewhere in the collision integral we just set $p = k = p' = k' = p_f$. We need to consider the value

$$\begin{aligned} (2b)K \cos\theta_{bK} &= (2b)^2 + (2b)p_f(\cos\theta_{bp} + \cos\theta_{bk}) \\ &= (2b)^2 + (2b)p_f(\cos\theta_{bp} + \cos\theta_{Pk} \cos\theta_{Pb} + \sin\theta_{Pk} \sin\theta_{Pb} \cos\varphi_{P,kb}). \end{aligned} \quad (\text{F82})$$

The term proportional to $\cos \varphi_{P,kb}$ implies that, in addition to (F71) and (F72), we also need to consider the following azimuthal integrals

$$\begin{aligned} & \sin \theta_{Pk} \sin \theta_{Pb} \int_0^{2\pi} d\varphi_{P,kb} \cos \varphi_{P,kb} (1 - \cos \theta_{pk})(1 - \cos \theta_{p'k'}) = \\ & \pi \left(1 - \frac{K^2 - 2p_f^2}{2p_f^2} \right) \left[1 - \left(\frac{K^2 - P^2 - p_f^2}{2Pp_f} \right)^2 \right] \left[1 - \left(\frac{(2b)^2 + P^2 - p_f^2}{2P(2b)} \right)^2 \right], \end{aligned} \quad (\text{F83})$$

$$\begin{aligned} & 2 \sin \theta_{Pk} \sin \theta_{Pb} \int_0^{2\pi} d\varphi_{P,kb} \cos \varphi_{P,kb} (\hat{\mathbf{p}} \cdot \hat{\mathbf{b}})(\hat{\mathbf{k}} \cdot \hat{\mathbf{b}})(1 - \cos \theta_{p'k'}) \\ & = 2\pi \left(1 - \frac{K^2 - 2p_f^2}{2p_f^2} \right) \left(\frac{P^2 - p_f^2 - (2b)^2}{2p_f(2b)} \right) \left[1 - \left(\frac{K^2 - P^2 - p_f^2}{2Pp_f} \right)^2 \right] \left[1 - \left(\frac{(2b)^2 + P^2 - p_f^2}{2P(2b)} \right)^2 \right]. \end{aligned} \quad (\text{F84})$$

Combining (F81) with the azimuthal integrals (F71), (F72), (F83) and (F84) one can calculate the result of (F 4 a) for the thermal conductivity:

- if $2b > 4p_f$, then $(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t., } \kappa}^{LR,LL} = 0$.
- if $4p_f \geq 2b > 2p_f$, then

$$\begin{aligned} & (\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t., } \kappa}^{LR,LL} = \frac{C^2}{4c^4} \frac{p_f^4}{2b} \frac{1}{(2\pi)^6} X'(p_f)^2 \frac{\beta^{-3}}{2} \\ & \pi(4p_f - 2b)^4 \frac{9(2b)^6 + 144(2b)^5 p_f + 1580(2b)^4 p_f^2 + 5120(2b)^3 p_f^3 + 9600(2b)^2 p_f^4 + 1024(2b) p_f^5 + 1024 p_f^6}{50400(2b)^2 p_f^4} [4c_2^2 + 2b_4] \\ & + \pi(4p_f - 2b) \frac{37(2b)^9 + 153(2b)^8 p_f + 1552(2b)^7 p_f^2 - 25242(2b)^5 p_f^4 + 108262(2b)^4 p_f^5 - 4172(2b)^3 p_f^4 - 68748(2b)^2 p_f^7 + 21928(2b) p_f^8 - 196608 p_f^9}{120 \cdot 840(2b)^2 p_f^4} [4c_2^2] \\ & - \pi \frac{105(2b)(2b-p_f)^3 (2b+p_f)^2 p_f^4 \log \left[\frac{3p_f}{2b-p_f} \right]}{840(2b)^2 p_f^4} [4c_2^2]. \end{aligned} \quad (\text{F85})$$

- if $2p_f \geq 2b > 0$, then

$$\begin{aligned} & (\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t., } \kappa}^{LR,LL} = \frac{C^2}{4c^4} \frac{p_f^4}{2b} \frac{1}{(2\pi)^6} X'(p_f)^2 \frac{\beta^{-3}}{2} \\ & \pi(2b) \frac{-27(2b)^7 - 420(2b)^5 p_f^2 + 8640(2b)^4 p_f^3 - 33600(2b)^3 p_f^4 + 28672(2b)^2 p_f - 403200(2b) p_f^6 + 1064960 p_f^7}{50400 p_f^4} [4c_2^2 + 2b_4] \\ & \pi(2b) \frac{111(2b)^9 + 126(2b)^8 p_f + 2835(2b)^7 p_f^2 - 26240(2b)^6 p_f^3 + 32250(2b)^5 p_f^4 + 49224(2b)^4 p_f^5 + 81774(2b)^3 p_f^6 + 48320(2b)^2 p_f^7 + 18900(2b) p_f^8 + 12600 p_f^9}{100800(2b)(2b+p_f) p_f^4} [4c_2^2] \\ & + \pi \frac{25200 p_f^4 [(2b)^2 - p_f^2]^3 \log \left[\frac{p_f}{|p_f - 2b|} \right] + 12600 p_f^4 [(2b)^2 - p_f^2]^3 \log \left[\frac{p_f}{p_f + 2b} \right]}{100800(2b)(2b+p_f) p_f^4} [4c_2^2]. \end{aligned} \quad (\text{F86})$$

For $LL \rightarrow RR$, one can proceed analogously and obtain

- if $2b > 4p_f$, then $(\mathcal{X}, \mathcal{C}_{e-e}\mathcal{X})_{\text{l.t., } \kappa}^{LL,RR} = 0$.
- if $4p_f \geq 2b > 2p_f$, then

\end{aligned}$$

Appendix G: Boltzmann Equation in 2-dimensional Basis

Here we solve the vectorized 2D Boltzmann equation (22)

$$\mathbf{S}_{E,T} = \mathbf{C} \mathbf{x}_{E,T}, \tag{G1}$$

in the basis (28) to obtain the electric and thermal conductivities, σ and κ . However, instead of solving a two-dimensional vector equation, we will make use of the results used in the main text (25) and (27), whereby the electric conductivity is accurately described by the momentum mode $F^0(p)$ due to the Sommerfeld expansion, whereas the thermal conductivity lives in the subspace perpendicular to this mode:

$$\sigma = \frac{2e^2\beta}{3} C^{-1,00} (S_E^0)^2, \quad \kappa = \frac{2}{3} \left(\frac{P^0}{S_E^0} \right)^2 \bar{S}_E^\dagger \bar{C}^{-1} \bar{S}_E. \tag{G2}$$

Again, due to the Sommerfeld expansion, only one function in the subspace perpendicular to $F^0(p)$ is needed to determine κ , simplifying calculations. Such function, in terms of our chosen basis (28), is obtained simply by projecting $F^1(p)$ into this subspace,

$$\bar{F}^1(p) \equiv (F^0 \hat{\mathbf{p}}, F^0 \hat{\mathbf{p}}) F^1 - (F^0 \hat{\mathbf{p}}, F^1 \hat{\mathbf{p}}) F^0 = \frac{2}{(2\pi)^2} \beta^{-2} [r^3 \beta (p_f - p) + 3c_2 r \beta (2p_f - p)]. \tag{G3}$$

All quantities appearing in (G2) are multiplicative, so there is no danger of generating misleading cancellations if they are calculated to leading order in the Sommerfeld expansion. The quantities dependent on the source terms are

$$S_E^0 = \frac{2}{(2\pi)^2} \beta^{-2} r^3, \quad P^0 = \frac{2}{(2\pi)^2} \beta^{-2} r^4, \quad \bar{S}_E^1 = \left[\frac{2}{(2\pi)^2} \right]^2 c_2 \beta^{-4} r^4. \tag{G4}$$

It is now useful to calculate the collision matrix elements individually. We define the relaxation times for

$$C_x^{00} = \frac{2}{(2\pi)^2} \beta^{-1} r^4 \tau_{\sigma,x}^{-1}, \quad \bar{C}^{11} = \left[\frac{2}{(2\pi)^2} \right]^3 c_2 \beta^{-5} r^8 \tau_{\kappa,x}^{-1}. \tag{G5}$$

Combining (G2), (G4) and (G5) one can see that the conductivities and the Lorenz ratio are given by

$$\sigma = \frac{4e^2 p_f^2}{3(2\pi)^2} \left[\sum_x \tau_{\sigma,x}^{-1} \right]^{-1}, \quad \kappa = \frac{4c_2 \beta^{-1} p_f^2}{3(2\pi)^2} \left[\sum_x \tau_{\kappa,x}^{-1} \right]^{-1}, \quad L \equiv \frac{\beta \kappa}{\sigma} = L_0 \left[\frac{\sum_x \tau_{\sigma,x}^{-1}}{\sum_x \tau_{\kappa,x}^{-1}} \right]. \tag{G6}$$

where $L_0 \equiv \frac{c_2}{e^2}$. For impurities (29), it is simple to find $\tau_{\text{imp}} = \tau_{\sigma,\text{imp}} = \tau_{\kappa,\text{imp}}$, as expected. For the other collision processes, these quantities depend on the temperature regime.

1. High Temperatures

For temperatures above the Bloch-Grüneisen temperature $T \gg T_{\text{BG}}$, it is simple to show using (E13) and (E28)

$$\tau_{\sigma,e\text{-ph}}^{-1}(T \gg T_{\text{BG}}) = \tau_{\kappa,e\text{-ph}}^{-1}(T \gg T_{\text{BG}}) = \beta^{-1} \frac{2(Cp_f^2)}{3(2\pi)c^2} \cdot \begin{cases} \frac{5}{2} & \text{if } T \gg T_{\text{BG,w}}, \\ 1 & \text{if } T \ll T_{\text{BG,w}}. \end{cases} \tag{G7}$$

The relaxation time for the electric conductivity is extracted simply enough from the sum of the collision integrals (E13), (E28) and (E30) for the $F^0(p)$ mode. The thermal relaxation time can be extracted from these same integrals and the collision integral matrix element for the mode orthogonal mode to $F^0(p)$,

$$\bar{C}_{\text{e-ph, h.t.}}^{11} = A^2(\boldsymbol{\mathcal{X}}_0, \mathcal{C}_{\text{e-ph}}\boldsymbol{\mathcal{X}}_0)_{\text{h.t.}} + B^2(\boldsymbol{\mathcal{X}}_1, \mathcal{C}_{\text{e-ph}}\boldsymbol{\mathcal{X}}_1)_{\text{h.t.}} - 2AB(\boldsymbol{\mathcal{X}}_0, \mathcal{C}_{\text{e-ph}}\boldsymbol{\mathcal{X}}_1)_{\text{h.t.}}, \quad (\text{G8})$$

where A and B are simply coefficients defined by through the Gram-Schmidt calculation of the orthogonal mode $\bar{F}^1 = -AF^0(p) + BF^1(p)$, i.e. $A = (F^0\hat{p}, F^1\hat{p})$ and $B = (F^0\hat{p}, F^0\hat{p})$. For electron-electron collisions, we showed that at high temperatures these are equivalent to a process of real phonon being emitted by a fermion and absorbed by another for the case of the thermal relaxation time, hence it is given by the expression in (G7). In the case of relaxation time associated to the electric conductivity, only processes that violate chirality effectively have non-vanishing relaxation times, and the contribution is given by an expression proportional to (F45)

$$\tau_{\sigma, \text{e-e}}^{-1}(T \gg T_{\text{BG}}) = \begin{cases} \beta^{-1} \frac{C(4b)^2}{6(2\pi)c^2} & \text{if } T \gg 2T_{\text{BG,W}}, \\ 0 & \text{if } T_{\text{BG,W}} \gg T. \end{cases} \quad (\text{G9})$$

Note that we have inserted an extra factor of $1/2$ to take into account that we are only considering the relaxation time provided by a single node, whereas the calculation in (F45) is done considering both nodes.

For temperatures below $T_{\text{BG,W}}$, virtual phonons that break chirality are no longer on-shell, i.e. with energies equal to ω_q , so the collision integral takes the low temperature form $\propto T^2$ that we discuss in the next section. However, this contribution is suppressed in comparison with the $\tau_{\sigma, \text{e-ph}}^{-1}(T \gg T_{\text{BG}})$, so we can effectively take it to be 0.

2. Low Temperatures

At low temperatures $T \ll T_{\text{BG}}$, the electric and thermal relaxation times no longer coincide for phonon emission and absorption processes. The electric relaxation time is again extracted from the 00 matrix component given in (E15). The thermal relaxation time is extracted from the low-temperature version of (G8). Note that now only intraband processes contribute to phonon absorption and emission for large internodal separations $2b > 2p_f$, as internode processes are suppressed because phonons do not have enough energy to connect nodes (E29). For small separations $2p_f < 2b$, this is no longer the case and they do provide a nonvanishing contribution (E31), but it is suppressed by an extra factor of c with respect to the intranode contribution. The relaxation times are thus

$$\tau_{\sigma, \text{e-ph}}^{-1}(T \ll T_{\text{BG}}) = \beta^{-5} \frac{12g_5C}{(2\pi)c^6p_f^2}, \quad (\text{G10})$$

$$\tau_{\kappa, \text{e-ph}}^{-1}(T \ll T_{\text{BG}}) = \beta^{-3} \frac{12g_5C}{c_2(2\pi)c^4}. \quad (\text{G11})$$

As for high temperatures, for electron-electron collisions only chirality-violating processes affect electric conduction, whereas both chirality-conserving and violating processes affect thermal conduction. Using (), this means that

$$\tau_{\sigma, \text{e-e}}^{-1}(T \ll T_{\text{BG}}) = \tau_{\sigma, \text{e-e}, \chi.v.}^{-1}(T \ll T_{\text{BG}}), \quad (\text{G12})$$

$$\tau_{\kappa, \text{e-e}}^{-1}(T \ll T_{\text{BG}}) = \frac{C^2p_f^3\beta^{-2}}{c_2(2\pi)^3c^4} \frac{1}{35} \left[8 + \frac{11 \cdot 19}{9 \cdot 5} \right] [4c_2^2 + 2b_4] + \tau_{\kappa, \text{e-e}, \chi.v.}^{-1}(T \ll T_{\text{BG}}), \quad (\text{G13})$$

where $\tau_{\sigma, \text{e-e}, \chi.v.}^{-1}(T \ll T_{\text{BG}})$ and $\tau_{\kappa, \text{e-e}, \chi.v.}^{-1}(T \ll T_{\text{BG}})$ are the chirality-breaking processes $LR \rightarrow LL$ and $LL \rightarrow RR$ to the electric and thermal conductivities, respectively, extracted from the collision integrals (F73) and (F75) for the former, and (F85), (F88), (F87), and (F88).
