Abstract

A unique perspective approach based on an analogy method is presented to solve the ray equation in a model of a continuous inhomogeneous medium, which has a spherically symmetric distribution. Basically, in the standard undergraduate physics teaching, the curved ray path caused by refraction in a medium with a continuously varying refractive index has always been a relatively difficult problem to solve. The equation is usually expressed in terms of partial differential equations (PDEs), which cannot be solved by analytical methods. Based on the analogy method, this work proposes the correspondence between ray refraction in an established medium model and the inverse-square central force system, succinctly obtaining their relation equations mathematically. We also verify the correctness of the method by qualitative and quantitative analysis. In terms of theoretical validation, we analyse the relation between Fermat's principle and Hamilton's principle, which lays a theoretical foundation for the analogy method. In addition, ray paths in the medium model were also simulated by numerical calculations based on COMSOL Multiphysics, and the results are in perfect agreement with the conclusions.

Keywords: optical refraction, analogy, conic curve, circularly symmetrical medium, Fermat's principle, Hamilton's principle

I. INTRODUCTION

Fermat's principle derives the conclusion that in homogeneous media the refractive index n is constant and light rays travel along straight lines.¹ However in graded index media in which n depends on the spatial coordinates, light rays propagate along curved paths. For example, in the field of laser ranging, due to the atmospheric effects, uneven refractive index causes the laser propagation path to bend, making the apparent distance, elevation angle, and velocity of the target measured by the lidar different from its true distance, elevation angle and velocity.² In the field of photoelectric detection, due to the influence of atmospheric refraction, the reconnaissance beam travels along a curve instead of a straight line.³ In the field of astronomical observation, atmospheric refraction is an important factor affecting the accuracy of astronomical measurement and celestial navigation.⁴ Mirage, a natural phenomenon, is a well-known illusion caused by the refraction of distant objects, resulting in a temperature gradient as the sun warms the ground. Consequently, light bends at the temperature gradient boundary due to different densities and refractive indices.^{5,6}

These problems are essentially the solution of the optical path equation in the continuous inhomogeneous media. We could presume such a medium exists, featuring a refractive index with the spherically symmetric distribution. In fact, there are no shortage of such models and spaces,⁷ for instance, partial regions of the refractive index of the earth atmosphere is symmetrically distributed in concentric circles⁸. RL White et al.⁹⁻¹¹ used the phenomenon of stellar light refraction through the atmosphere to navigate the satellite autonomously. Jennifer C. Ricklin et al.¹² studied the effects of the atmospheric channel on laser communication. Liu et al.¹³ studied the influence of atmospheric refraction on the laser timing deviation in dual-wavelength space. In fact, research about light ray paths in spherically symmetric continuous inhomogeneous media has always been a significant subject to discuss. In previous methods, this problem is generally solved by building mathematical models, which are usually expressed in terms of partial differential equations (PDEs)^{14,15}. In this paper, a novel method of analogy between optical theory and the mechanical theory is proposed. The aim is to avoid the complicated calculation process and provide a unique perspective approach for solving similar problems.

II. THEORETICAL BASIS

In continuous inhomogeneous media, light rays propagate along curved paths. For the sake of simplicity, we assume that the refractive index varies only along the y -direction (Fig.1). Such a medium can be thought of as a limiting case of a medium consisting of a continuous set of thin slices of media of different refractive indices. At each interface, the light ray satisfies Snell's law. In the spherically symmetrical medium model discussed in the following sections, this idea of discretization is applied.¹⁵

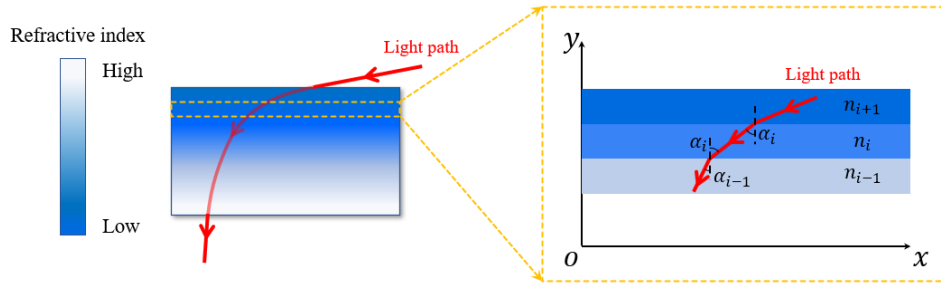

FIG. 1. Light path in the simplest continuously changing medium and the application of the infinitesimal method.

The other theoretical basis is the inverse-square central force system. The following kinematics and dynamics equations are crucial.

1. The trajectory of a particle in the inverse-square central force system is a conic curve,¹⁶ and the shape of the conic curve is determined by the energy of the particle (E),¹⁷ i.e.

- When $E = 0, e = 1$, the orbit is a parabola.
- When $E < 0, e < 1$, the orbit is an ellipse.
- When $E > 0, e > 1$, the orbit is a hyperbola.

2. The eccentricity of the conic curve is¹⁷

$$e = \sqrt{1 + \frac{2h^2E}{mk^2}} \quad (1)$$

where $h = |\vec{r}|^2 \dot{\theta}$,

\vec{r} : the position of the mass point relative to the center of force.

θ : the angular displacement of the particle relative to the initial position.

E, m : the energy and the mass of the particle respectively.

k : the proportional coefficient of the inverse-square central force $F(r) = -\frac{km}{r^2}$.

3. The equation of the conic section is¹⁷

$$r = \frac{\frac{h^2}{k}}{1 + \sqrt{1 + \frac{2h^2 E}{mk^2} \cos(\theta - \theta_0)}} \quad (2)$$

III. THEORETICAL MODEL

A. Geometry properties

Based on the method of **section 2**, the medium model can be discretized into a continuous set of thin slices with different refractive indices(Fig.2).

At each interface, the light ray satisfies Snell's law and the following equation is obtained

$$n_0 \sin i_0 = n_1 \sin i'_0, \quad n_1 \sin i_1 = n_2 \sin i'_1, \quad \dots \quad (3)$$

In $\triangle ABO$, by the law of sine

$$\frac{\sin i'_0}{r_1} = \frac{\sin i_1}{r_0} \quad (4)$$

Substituting Eq.(4) into Eq.(3) yields

$$r_0 n_0 \sin i_0 = r_1 n_1 \sin i_1, \dots \quad (5)$$

Similarly, we can state that the product

$$r_0 n_0 \sin i_0 = r_1 n_1 \sin i_1 = r_2 n_2 \sin i_2 = \dots \quad (6)$$

is an invariant of the ray path; we will denote this invariant by β . It may be determined from the fact that if the ray initially makes an angle i_0 at a point where the refractive index is n_0 , then the value of β is $n_0 \sin i_0$. Thus, in the limiting case of a continuous variation of the refractive index, the piecewise straight lines form a continuous curve(Fig.2), which is determined from the equation

$$r_i n_i \sin i = r_0 n_0 \sin i_0 = \beta \quad (7)$$

implying that as the refractive index of this medium model changes, the ray path bends in such a way that the product $r_i n_i \sin i_i$ remains constant. Eq.(7) can be used to derive the ray equation. In fact, *chapter 14, Springer Handbook of Lasers and Optics*¹⁵ has already provided a detailed method of obtaining the PDEs of the medium with a continuous inhomogeneous refractive index, which shows a high level of mathematical and physical complexity for undergraduate students.

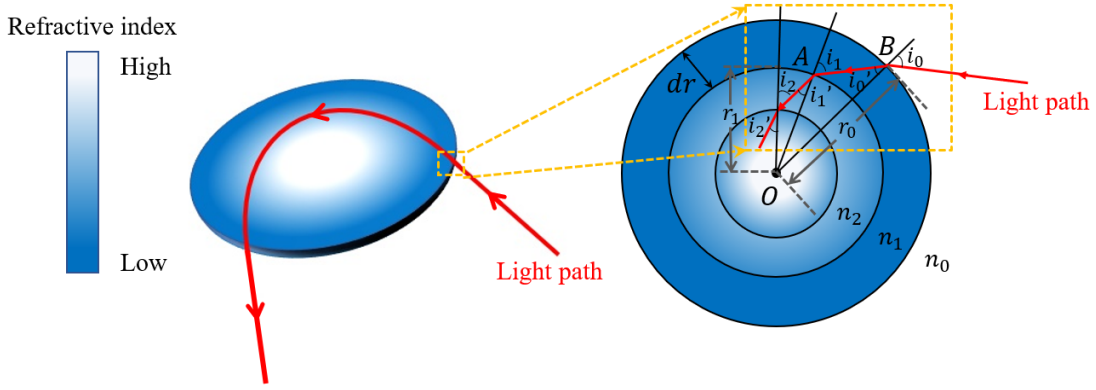

FIG. 2. Light path in a layered structure of the medium model

B. Analogy relation equation

Considering Eq.(7) and the law of the angular momentum conservation, we find that there is a high similarity in forms of mathematical equations. In fact, we can presume the propagation of light paths as the motion of a particle. The refractive index n can be analogized to the momentum p of the particle m . Similarly, the origin of the medium model should be the center of the inverse-square central force system. Therefore, the original optical problem can be transformed into a mechanical problem. The theory mentioned in **section 2** has proved that the motion trajectory of the particle m is a conic curve in the inverse-square central force system. Hence, when the optical path presents a conic refraction in the medium with a spherically symmetric refractive index, the method of the inverse-square central force system can be used to study the relevant problems of the optical path quickly and concisely.

Fig.3 shows the analogy of the physical quantities in this optical and mechanical model.

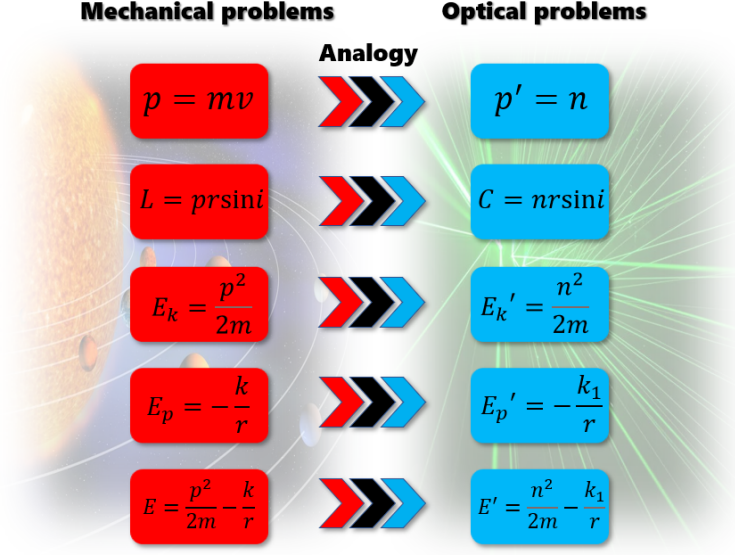

FIG. 3. Analogue diagram of physical quantities.

C. Qualitative analysis

For ease of understanding, we define a virtual concept of “feature point” in our medium model, i.e. there is a feature point J in the model if it satisfies the following three properties:

- The ray is perpendicular to the x axis of our coordinate system.
- The distance from the ray path to the origin of the coordinate is $|OJ| = r^*$.
- The refractive index of the feature point J is n^* .

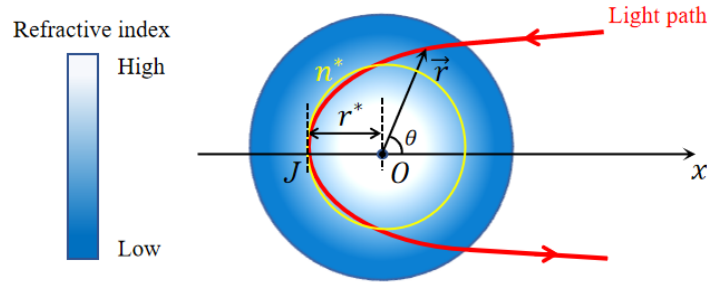

FIG. 4. Light path diagram and the meaning of each physical quantity.

Based on **section 3.2**, the inverse-square central force system could be introduced since

the light is refracted in a conical shape in the medium model. Thus we assume the origin O as the center of the system.(Fig.3)

Considering the particle's kinetic energy $E'_k = \frac{n^2}{2m}$, potential energy $E'_p = -\frac{k_1}{r}$, we have the energy as a constant, $E' = \frac{n^2}{2m} - \frac{k_1}{r}$. We denote this invariant by λ , thus, $n^2 = 2m\lambda + \frac{2mk_1}{r}$. Obviously, the value of λ can be determined by the feature point J of the medium, i.e. $\lambda = \frac{n^{*2}}{2m} - \frac{k_1}{r^*}$. Then, the refractive index equation is

$$n = n(r) = n^* \sqrt{1 + A(\frac{1}{r} - \frac{1}{r^*})} \quad (8)$$

where $A = \frac{2mk_1}{n^{*2}}$.

According to the analogy of potential energy that in equation $E'_p = -\frac{k_1}{r}$, we have $k_1 = GMm$. Therefore, the energy equation is

$$E' = \frac{n^{*2}}{2m} - \frac{An^{*2}}{2mr^*} \quad (9)$$

i.e.

- When $E' = 0$, the orbit is a parabola.
- When $E' < 0$, the orbit is an ellipse.
- When $E' > 0$, the orbit is a hyperbola.

D. Quantitative analysis

From Eq.(9), the value of A determines the shape of the light path. Now we quantitatively discuss the relation between A and the light path equation.

By setting the polar coordinate equation of the conic curve to be $r = \frac{\tilde{p}}{1 - e \cos \theta}$ and according to Eq.(1) and the principle of analogy, we have

$$e = \sqrt{1 + \frac{2E'L^2}{G^2M^2m^3}} \quad (10)$$

$$= \sqrt{1 + \frac{4r^*}{A^2}(r^* - A)} \quad (11)$$

where $L = n^*r^*$ (Fig.3), $E' = \frac{n^{*2}}{2m} - \frac{An^{*2}}{2mr^*}$, $GM = \frac{An^{*2}}{2m}$ (Eq.(9)).

Because $\tilde{p} = r^*(1 - e \cos \pi) = r^*(1 + |\frac{2r^*}{A} - 1|)$, the curve equation is

$$r = \frac{\tilde{p}}{1 - e \cos \theta} = \frac{(1 + |\frac{2r^*}{A} - 1|)r^*}{1 - |\frac{2r^*}{A} - 1| \cos \theta} \quad (12)$$

Eq. (12) shows the light path is a conic whose equation is determined by medium parameters r^* and A . Eq.(12) demonstrates the results are consistent with **section 3.3**, since the orbit is a parabola when

$$|\frac{2r^*}{A} - 1| = 1 \quad (13)$$

the orbit is an ellipse when

$$|\frac{2r^*}{A} - 1| < 1 \quad (14)$$

the orbit is a hyperbola when

$$|\frac{2r^*}{A} - 1| > 1 \quad (15)$$

IV. THEORETICAL VALIDATION

A. The mathematical connection between mechanics and optics

We consider an equivalent mechanical problem of the inverse-square central force system (Fig.5), where a particle m passes through an interface in the medium with velocity \vec{v}_1 and \vec{v}_2 .

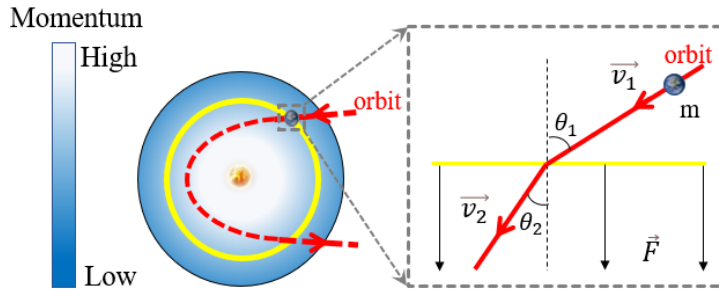

FIG. 5. Particle in the inverse-square central force system.

By the conservation of horizontal momentum (p_x) and the energy (E), we have

$$mv_1 \sin \theta_1 = mv_2 \sin \theta_2 \quad (16)$$

$$\frac{1}{2}mv_1^2 + E_{p1} = \frac{1}{2}mv_2^2 + E_{p2} = \gamma \quad (17)$$

Similarly, when it comes to an equivalent optical problem (Fig.6) where light passes through an interface with refractive index being n_1 , n_2 respectively, we have Snell's Law $n_1 \sin \theta_1 = n_2 \sin \theta_2$. Combined with Eq.(16) and Eq.(17), we could obtain Eq.(18) in the same form of Eq.(17), i.e.

$$\frac{n_1^2}{2m} + \alpha^2 E_{p1} = \frac{n_2^2}{2m} + \alpha^2 E_{p2} = \alpha^2 \gamma \quad (18)$$

where $\frac{n_1}{mv_1} = \frac{n_2}{mv_2} = \alpha$.

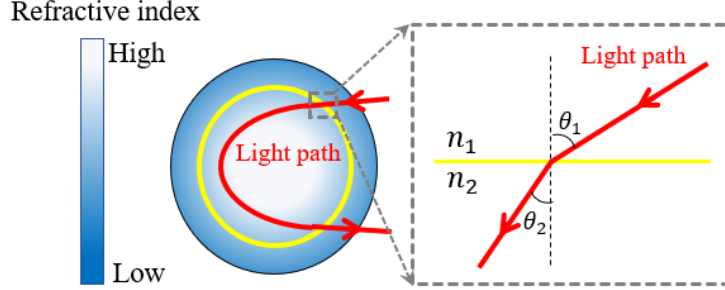

FIG. 6. Light path in the medium with a concentric symmetric index.

Eq.(18) shows that when using the analogy relationship of the physical quantities in Fig.3 to study optical problems, the physical meanings assigned are all based on strict mathematical derivations. The construction of analogy thinking is self-consistent in mathematics and physical logic.

B. The theoretical nature of the optical-mechanical analogy

Pierre de Fermat (1601-1665) postulated that

the path between two points taken by a ray of light leaves the optical length stationary under variations in a family of nearby paths.

Mathematically, Fermat's principle can be written as

$$T = \int_{r_1}^{r_2} dt = \text{stationary} \quad (19)$$

The points $r_1(x_1, y_1, z_1)$ and $r_2(x_2, y_2, z_2)$ are two fixed points in space. If we represent a general path s from r_1 to r_2 in the form $x = x(z), y = y(z)$, with the velocity as v , and define the refractive index n to be $n(x, y, z) = \frac{1}{v}$, Eq.(19) becomes¹⁸

$$\int_{z_1}^{z_2} n(x, y, z) \sqrt{\dot{x}^2 + \dot{y}^2 + 1} dz = \text{stationary} \quad (20)$$

In 1744, Maupertuis proposed that “Nature, in the production of its effects, does so always by the simplest means.”¹⁹ Noether’s theorem tells us that in a world without symmetry, the laws of physics change.²⁰ In fact, the minimization of time revealed by Fermat’s principle can remind us of the minimization of action stated by Hamilton’s principle, which is also based on the optical-mechanical analogy.²¹

Hamilton’s principle (1834) or principle of least action can be written as:²²

the motion of the system from fixed time t_1 to fixed time t_2 is such that the line integral (called the action or the action integral).

$$S = \int_{t_1}^{t_2} \mathcal{L}[x(t), \dot{x}(t), t] dt \quad (21)$$

where S is a functional of the function or path $x(t)$, \mathcal{L} is a Lagrangian system and $\dot{x}(t) = dx/dt$. S has a stationary value for the actual path of the motion. $\delta S = 0$ is the condition to have a minimum value.

For Eq.(20), in fact, we can identify the function

$$\mathcal{L}(x, y, \dot{x}, \dot{y}, z) = n(x, y, z) \sqrt{\dot{x}^2 + \dot{y}^2 + 1}$$

as the equivalent of a Lagrangian system.¹⁸

TABLE I. Mathematical form of Fermat’s principle and Hamilton’s principle

Fermat’s principle	Hamilton’s principle
$\int_{r_1}^{r_2} dt = \int_{r_1}^{r_2} n(x, y, z) ds = \text{stationary}$	$\int_{t_1}^{t_2} \mathcal{L}[x(t), y(t), \dot{x}(t), \dot{y}(t), t] dt = \text{stationary}$
$\int_{z_1}^{z_2} \mathcal{L}[x(z), y(z), \dot{x}(z), \dot{y}(z), z] dz = \text{stationary}$	

We see from Table.I that Fermat’s principle takes a stationary value for a function of a length coordinate and Hamilton’s principle takes a stationary value for functions of time. Or, Fermat’s principle takes a minimum value for the transit time with the endpoints, r_1, r_2 , fixed in space, whereas Hamilton’s principle takes a minimum value for the action with the endpoints, $(r_l, t_l), (r_2, t_2)$ fixed in both space and time.¹⁸

Therefore, Fermat’s principle is equivalent to Hamilton’s principle mathematically, which essentially reveals the correctness of the analogy method.

Moreover, this paper²³ also demonstrates the two different interpretations of Hamilton’s characteristic function in optics and mechanics, which could also further verify the underlying principles.

V. COMPUTER SIMULATION

The description of the laws of physics for space- and time-dependent problems are usually expressed in terms of partial differential equations (PDEs), which cannot be solved with analytical methods. Instead, an approximation of the equations can be constructed, typically based upon different types of discretizations, which can be computed numerically through the finite element method (FEM). And this can also be applied to the curved ray equation in the aforementioned medium model.

COMSOL Multiphysics is based on the FEM. It solves PDEs to achieve the simulation of real physical phenomena and uses mathematical methods to solve the physical phenomena in the real world. The propagation of light is modelled in the geometrical optics approximation. Thus, the method of choice is ray tracing. Non-sequential tracing is used, in which no predefined paths are assumed for rays. COMSOL Multiphysics Ray Tracing module is based on Hamiltonian optics and the FEM. The ray tracer is time-dependent and employs a Monte-Carlo approach.²⁴

Here we modeled the concentric symmetric continuous inhomogeneous medium and established the rectangular coordinate system with the origin as the center of the medium. Now the goal is to verify Eq.(13) - Eq.(15) obtained through analogy method, which defines the relation between conic shapes and medium parameters. The input-output parameters are shown as Table II.

From Eq.(13) - Eq.(15), the following conclusions hold:

- The light path is a parabola if: $|\frac{2r^*}{A} - 1| = 1 \implies r^* = A, (r^* < r_0)$
- The light path is an ellipse if: $|\frac{2r^*}{A} - 1| < 1 \implies 0 < r^* < A, (r^* < r_0)$
- The light path is a hyperbola if: $|\frac{2r^*}{A} - 1| > 1 \implies r^* > A, (r^* < r_0)$

In fact, we can take any value of the input that satisfies the corresponding restrictions. Here

TABLE II. The input-output parameters in COMSOL Multiphysics

Input	Intermediate variable	Output
$n(r), n(x, y)$		
r_0		
n_0	n^*	light path and its coordinates
T_s		
Exit point of light (x_0, y_0)		
$\{(r_i^*, A_i) f(r_i^*, A_i) = 0, i = 1, 2, 3, \dots\}$		

¹ $n(r)/n(x, y)$ (polar/rectangular coordinate system) is the equation of the refractive index distribution.

² r_0 is the maximum radius of the concentric symmetric medium.

³ n_0 is the refractive index of the periphery of the medium.

⁴ T_s is the simulation time.

⁵ (x_0, y_0) : For the sake of simplicity, we set the feature point $J(-r^*, 0)$ of the medium as the exit point of the light ray.

⁶ $\{(r_i^*, A_i) | i = 1, 2, 3, \dots\}$ is series of different parameters combinations.

⁷ n^* is the refractive index value at the feature point J .

we define a set of the input {'parabola', 'ellipse', 'hyperbola'} as

$$r_0 = \{2, 2, 2\}(\text{meters})$$

$$n_0 = \{1, 1, 1\}(\text{meters})$$

$$T_s = \{17, 20, 12\}(ns)$$

$$\text{Exit point}(x, y) : \{(-0.5, 0), (-0.5, 0), (-0.5, 0)\}(\text{meters})$$

$$\{(r^*, A) | f(r^*, A) = 0\} = \{(0.5, 0.5), (0.5, \frac{7}{12}), (0.5, \frac{2}{5})\}$$

$$\begin{cases} n(r)_{\text{parabola}} = n^* \sqrt{1 + A(\frac{1}{r} - \frac{1}{r^*})} = \sqrt{\frac{2}{r}} \implies n(x, y) = \sqrt{2}(x^2 + y^2)^{-\frac{1}{4}} \\ n(r)_{\text{ellipse}} = n^* \sqrt{1 + A(\frac{1}{r} - \frac{1}{r^*})} = \sqrt{\frac{14}{3} \cdot \frac{1}{r} - \frac{4}{3}} \implies n(x, y) = \sqrt{\frac{14}{3\sqrt{x^2+y^2}} - \frac{4}{3}} \\ n(r)_{\text{hyperbola}} = n^* \sqrt{1 + A(\frac{1}{r} - \frac{1}{r^*})} = \sqrt{\frac{1}{r} + \frac{1}{2}} \implies n(x, y) = \sqrt{\frac{1}{\sqrt{x^2+y^2}} + \frac{1}{2}} \end{cases}$$

where

$$\begin{cases} (n_0 = 1, r_0 = 2)_{\text{parabola}} \in \{(n, r) | n - n^* \sqrt{1 + A(\frac{1}{r} - \frac{1}{r^*})} = 0, r^* = A\} \implies n^* = 2 \\ (n_0 = 1, r_0 = 2)_{\text{ellipse}} \in \{(n, r) | n - n^* \sqrt{1 + A(\frac{1}{r} - \frac{1}{r^*})} = 0, 0 < r^* < A\} \implies n^* = 2\sqrt{2} \\ (n_0 = 1, r_0 = 2)_{\text{hyperbola}} \in \{(n, r) | n - n^* \sqrt{1 + A(\frac{1}{r} - \frac{1}{r^*})} = 0, A < r^* < r_0\} \implies n^* = \frac{\sqrt{10}}{2} \end{cases}$$

Filting out the secondary reflections, the outputs (the light path) are shown in Fig.7.

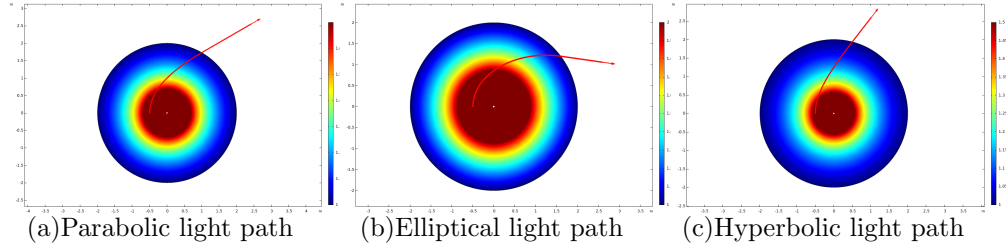

FIG. 7. Comparison between simulation results and theory.

Now we analyse the quantitative outputs (coordinates of simulation results) and perform data visualization on it. The theoretical trajectory equation can be obtained from Eq.(12), i.e.

$$\begin{aligned} \text{parabola: } r &= \frac{1}{1 - \cos\theta} \implies \sqrt{x^2 + y^2} - x - 1 = 0 \\ \text{ellipse: } r &= \frac{\frac{6}{7}}{1 - \frac{5}{7}\cos\theta} \implies \sqrt{x^2 + y^2} - \frac{5}{7}x - \frac{6}{7} = 0 \\ \text{hyperbola: } r &= \frac{5}{4 - 6\cos\theta} \implies 2\sqrt{x^2 + y^2} - 6x - 5 = 0 \end{aligned}$$

Thus, Fig.8 shows that the error is 0 when the light ray is inside the medium model, i.e., the simulation results of three different light paths are consistent with the theory.

VI. CONCLUSION

Consider that in daily life, the problem of the curve propagation of the light path such as the laser ranging, photoelectric detection, astronomical observation and other fields referred to in the introduction are often encountered. In fact, in the earth's atmosphere, spherical solutions are possible for certain ideal conditions with specific lapse rates. This proves the possibly of real situations that fulfill the requirements for the conic path trajectories as discussed. Moreover, based on the equations in this paper, artificial media causing a conic

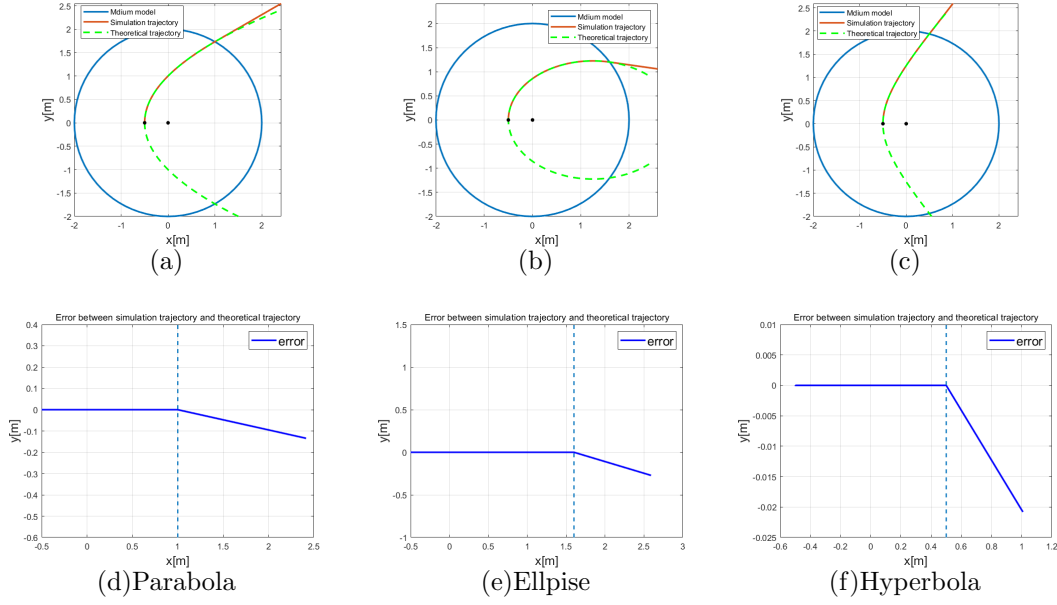

FIG. 8. Trajectory contrast (a)(b)(c) and their corresponding error graphs (d)(e)(f) between simulation and theoretical results of three cases.

light path can also be easily designed theoretically. In all, when the optical path is needed to be made a conic curve, the inverse-square central force system can be used for analogy study. When the optical path is needed to be made a special curve, the inverse-cubic or even the n^{th} inverse central force system can also be used to solve the problem similarly. Thus we can extend the application of such methods to more general applications, which is an important application example of the mechanical analogy of optical principles.
