Abstract

We explore a model of dark matter (DM) that can explain the reported discrepancy in the muon anomalous magnetic moment and predict a large electric dipole moment (EDM) of the muon. The model contains a DM fermion and new scalars whose exclusive interactions with the muon radiatively generate the observed muon mass. Constraints from DM direct and indirect detection experiments as well as collider searches are safely evaded. The model parameter space that gives the observed DM abundance and explains the muon $g - 2$ anomaly leads to the muon EDM of $d_\mu \simeq (4-5) \times 10^{-22} e \text{ cm}$ that can be probed by the projected PSI muEDM experiment. Another viable parameter space even achieves $d_\mu = \mathcal{O}(10^{-21}) e \text{ cm}$ reachable by the ongoing Fermilab Muon $g - 2$ experiment and the future J-PARC Muon $g - 2/\text{EDM}$ experiment.

1 Introduction

The near-future discovery of the muon electric dipole moment (EDM) is highly expected by the reported discrepancy in the muon anomalous magnetic moment $(g - 2)_\mu$, which may indicate the existence of physics beyond the Standard Model (SM) at or below the TeV scale [1–4] (for a review, see ref. [5]), because the same new physics contribution naturally has the imaginary part which is relevant to the EDM. The current upper limit on the muon EDM is $|d_\mu| < 1.8 \times 10^{-19} e \text{ cm}$ (95% C.L.) [6]. There is also a study on indirect bounds on the muon EDM by measuring EDMs of heavy atoms and molecules, which indicates $|d_\mu| < 2 \times 10^{-20} e \text{ cm}$ [7]. Moreover, the sensitivity to the muon EDM will be improved in the near future: the ongoing Fermilab Muon $g - 2$ experiments [8] and projected J-PARC Muon $g - 2$ /EDM experiment [9] will explore the muon EDM at the level of $10^{-21} e \text{ cm}$, while the Paul Scherrer Institute (PSI) muEDM experiment [10–12] will reach the sensitivity of $6 \times 10^{-23} e \text{ cm}$.

A fermion EDM d_f is described by a dimension-five operator $\mathcal{L} \supset -\frac{i}{2} d_f \bar{f} \sigma_{\mu\nu} \gamma^5 f F^{\mu\nu}$ where f is a Dirac fermion, $\sigma^{\mu\nu} \equiv \frac{i}{2} [\gamma^\mu, \gamma^\nu]$ and $F^{\mu\nu}$ is the photon field strength. Since this operator requires a chirality flip and left- and right-handed fermions carry different charges in the SM, we actually need a Higgs field insertion which makes the EDM operator effectively dimension-six. Therefore, a new physics contribution to a fermion EDM scales as v_H/M^2 where v_H and M denote the Higgs vacuum expectation value (VEV) and a new physics mass scale, respectively.

To estimate the expected size of the muon EDM, we can consider four classes of new physics that generate the muon EDM as well as the anomalous magnetic moment ¹:

- **Spurion approach.** The chirality flip required to generate the EDM operator is provided by the muon Yukawa coupling y_μ or some coupling proportional to y_μ . When the muon EDM d_μ is generated at the k -loop level, we expect

$$d_\mu \sim \delta_{\text{CPV}} \left(\frac{\lambda^2}{16\pi^2} \right)^k \frac{m_\mu}{M^2}. \quad (1.1)$$

Here, δ_{CPV} and λ represent the size of CP-violating phases and couplings involved in the loop, and m_μ is the muon mass. Models in this class have been discussed in refs. [15–21].

- **Flavor changing approach.** If the muon is converted to the tau lepton by a lepton flavor violating (LFV) interaction, the chirality flip can be provided by the

¹The similar classification has been presented for the case of the electron EDM in ref. [13] (see also ref. [14]).

tau Yukawa coupling y_τ . In this case, we find

$$d_\mu \sim \delta_{\text{CPV}} \frac{y_{\mu\tau}^2}{\lambda^2} \left(\frac{\lambda^2}{16\pi^2} \right)^k \frac{m_\tau}{M^2}, \quad (1.2)$$

with a LFV coupling $y_{\mu\tau}$ and the tau lepton mass m_τ . Refs. [22–25] have explored models in this class. Note that if the model has a scalar leptoquark with appropriate charge assignment, the chirality flip can be picked up from a quark Yukawa coupling, e.g., the top Yukawa coupling. Moreover, there is an enhancement due to the color factor $N_C = 3$. Refs. [26–32] have explored such a possibility in the context of the electron EDM and ref. [33] presented a general discussion for the case of the muon $g - 2$ and EDM. In addition, a model with extra vector-like leptons also has a possibility to predict a large muon EDM [34, 35] due to the chirality flip on a heavy lepton line.

- **Radiative stability approach.** New physics that produces the muon EDM also generates the muon mass by removing the attached photon. When we just assume that such a contribution to the muon mass does not exceed the correct value, the size of the muon EDM is expected to be

$$d_\mu \sim \delta_{\text{CPV}} \frac{m_\mu}{M^2}, \quad (1.3)$$

because the same loop factor and coupling λ are shared by the generated muon mass and EDM.

- **Tuning approach.** If the muon mass generated by new physics that produces the muon EDM exceeds the correct value, a fine-tuning is required. This (unlikely but logical) possibility allows us to obtain a very large muon EDM which is bounded by

$$d_\mu \sim \delta_{\text{CPV}} \lambda \left(\frac{\lambda^2}{16\pi^2} \right)^k \frac{v_H}{M^2} \lesssim \delta_{\text{CPV}} \frac{4\pi v_H}{M^2}, \quad (1.4)$$

for $\lambda \lesssim 4\pi$.

Table 1 shows mass scales of new physics that produce the muon EDM at the one/two-loop level probed by the projected PSI muEDM experiment [10–12] (the ongoing Fermilab Muon $g - 2$ experiment [8] and the future J-PARC Muon $g - 2$ /EDM experiment [9]). Aside from the tuning approach, the table indicates that the radiative stability approach generates the largest muon EDM and its near-future measurements can probe mass scales larger than the TeV scale. The present paper explores this fascinating possibility for

	1-loop	2-loop
Spurion	300 GeV (75 GeV)	16 GeV (4 GeV)
Flavor changing	580 GeV (140 GeV)	30 GeV (7 GeV)
Radiative stability	5900 GeV (1400 GeV)	
Tuning	1.0×10^6 GeV (2.5×10^5 GeV)	

Table 1: Mass scales of new physics that produce the muon EDM at the one/two-loop level probed by the projected PSI muEDM experiment [10–12] (the Fermilab Muon $g-2$ and J-PARC Muon $g-2$ /EDM experiments [8, 9]) for each approach presented in the main text. Here, we assume $\lambda \approx 0.65$ of around the weak coupling constant and $y_{\mu\tau} \approx 0.3$ which is roughly the maximum value allowed by the measurement of the branching ratio of $h \rightarrow \mu\tau$ (see, e.g., ref. [23]). For the leptoquark model, the mass scale is enhanced by $(y_{\mu t}/y_{\mu\tau})\sqrt{N_C m_t/m_\tau} \approx 57 y_{\mu t}$ where $y_{\mu t}$ is the leptoquark coupling to the muon and the top quark.

the first time through the study of a concrete model to realize the radiative stability approach ².

We consider a model of dark matter (DM) that can address the muon $g-2$ anomaly. A DM fermion and new scalars exclusively couple to the muon, which leads to the radiative generation of the muon mass. The model contains a new CP-violating phase and produces the muon EDM. We will find that the model parameter space to give the observed DM abundance and explain the muon $g-2$ anomaly leads to the muon EDM of $d_\mu \simeq (4-5) \times 10^{-22} e\text{cm}$ probed by the PSI muEDM experiment. Furthermore, it will be shown that another viable parameter space even achieves $d_\mu = \mathcal{O}(10^{-21}) e\text{cm}$ reached by the Fermilab Muon $g-2$ and J-PARC Muon $g-2$ /EDM experiments, which is consistent with the estimate of Table 1.

The rest of the paper is organized as follows. Section 2 starts with the description of our DM model and explores the mass spectrum. We then calculate the radiatively generated muon mass and coupling to the Higgs boson and the muon EDM as well as the anomalous magnetic moment. They are all induced at the one-loop level. We also discuss deviations of the muon couplings to the Higgs and Z bosons from those of the SM. In section 3, phenomenology of DM in our model is explored. Section 4 summarizes the independent parameters of the model, and then presents our results to identify the parameter space that gives the observed DM abundance and explains the muon $g-2$

²In ref. [36], the author commented on the possibility of a large muon EDM in the context of the radiative stability approach.

Table 2: Charge assignments for the relevant particles. L_L^μ and μ_R represent the second generation of the left- and right-handed leptons and H is the SM Higgs field. The hypercharge of $\psi_{L,R}$ is taken as $Y_\psi = 0$ in the present paper. L_μ and X are Z_2 symmetries associated with the muon number and the exotic particle number, while S_a is a softly broken Z_2 symmetry to forbid the tree-level muon Yukawa coupling.

anomaly and indicate the size of the muon EDM. In section 5, we give conclusions and discussions. Loop integrals and full one-loop expressions are summarized in appendices.

2 Model description

Our DM model is based on models proposed in ref. [37], which radiatively generate the muon mass and explain the muon $g - 2$ anomaly. The model contains a single Dirac fermion ψ and two scalar fields ϕ, η . Charge assignments for the relevant particles are shown in Table 2. The present paper focuses on the case with $Y_\psi = 0$ ³. We introduce two Z_2 symmetries L_μ, X associated with the muon number and the exotic particle number, respectively. The former symmetry⁴ makes it possible to avoid severe constraints from lepton flavor violating processes, while the latter one stabilizes the lightest exotic particle which is identified as DM. In addition, we assume a softly broken Z_2 symmetry S_a to forbid the tree-level muon Yukawa coupling. The charge assignments

³The model with $Y_\psi = -1$ has a singlet real scalar η , and a CP phase appears in the scalar sector. In this case, however, CP violating effects necessarily involve the SM Higgs VEV, and therefore, the muon EDM is suppressed when the exotic particle masses are set to be around TeV.

⁴The L_μ symmetry can be enhanced to a global $U(1)_{L_\mu}$ symmetry when $\lambda''_{H\phi}$ in Eq. (2.2) is set to be zero. This value is irrelevant to our current analysis. Note that even if we do not have $U(1)_{L_\mu}$ symmetry, $B - 3L_e$ number and $B - 3L_\tau$ number are conserved (for a review, see, e.g., Ref. [38]) and there is no washout of baryon asymmetry in the early universe.

lead to the following terms in the Lagrangian:

$$\mathcal{L} \supset \left(-y_\phi \bar{L}_L^\mu \phi^\dagger \psi_R - y_\eta \bar{\psi}_L \eta \mu_R - m_D \bar{\psi}_L \psi_R - \frac{m_{LL}}{2} \bar{\psi}_L \psi_L^c - \frac{m_{RR}}{2} \bar{\psi}_R^c \psi_R + \text{h.c.} \right) - V_{\text{scl}}, \quad (2.1)$$

$$V_{\text{scl}} = \sum_{s=H,\phi,\eta} \left[m_s^2 s^\dagger s + \frac{\lambda_s}{2} (s^\dagger s)^2 \right] + \lambda_{H\phi} (H^\dagger H) (\phi^\dagger \phi) + \lambda_{H\eta} (H^\dagger H) (\eta^\dagger \eta) + \lambda_{\phi\eta} (\phi^\dagger \phi) (\eta^\dagger \eta) \\ + \lambda'_{H\phi} (H^\dagger \phi) (\phi^\dagger H) + \left(a H \eta^\dagger \phi + \frac{\lambda''_{H\phi}}{2} (H^\dagger \phi)^2 + \text{h.c.} \right). \quad (2.2)$$

Note that all couplings in V_{scl} and $y_{\phi,\eta}$ can be real and positive by field redefinitions, while one phase of m_D , m_{LL} , and m_{RR} cannot be removed. In fact, a combination $m_{LL} m_{RR} / m_D^2$ is independent of phase rotations, and we define a physical phase in the model as

$$\theta_{\text{phys}} \equiv \frac{1}{2} \arg \left(\frac{m_{LL} m_{RR}}{m_D^2} \right) = \frac{1}{2} (\theta_L + \theta_R - 2\theta_D), \quad (2.3)$$

where $\theta_{D,L,R}$ denote phases of m_D , m_{LL} , and m_{RR} , respectively. Since ψ is singlet under the SM gauge symmetry, we can define the left- and right-handed Majorana fermions as $\psi_{L,R}^M \equiv \psi_{L,R} + (\psi_{L,R})^c$ with $\psi_{L,R} = P_{L,R} \psi$ and $(\psi_{L,R})^c \equiv i\gamma^2 (\psi_{L,R})^*$. We assume that the exotic scalars ϕ, η do not acquire nonzero VEVs. As a result, no mixing between H and ϕ/η is induced, and hence we can parameterize the SM Higgs field H as

$$H = \begin{pmatrix} G^+ \\ \frac{1}{\sqrt{2}} (v_H + h^0 + iG^0) \end{pmatrix}, \quad (2.4)$$

where $v_H = 246.22$ GeV is the SM Higgs VEV, G^+ and G^0 are Nambu-Goldstone modes, and h^0 is the SM Higgs boson. Note that a minimization condition leads to

$$m_H^2 = -\frac{1}{2} \lambda_H v_H^2. \quad (2.5)$$

Below, we will present the mass spectrum of exotic particles and calculate the radiatively generated muon mass and coupling to the Higgs boson and the muon EDM as well as the anomalous magnetic moment. Deviations of the muon couplings to the Higgs and Z bosons from those of the SM will be also discussed. Note that for the neutrino sector, we need a further extension to reproduce the correct neutrino mixing angles, due to the muon number symmetry. We discuss some possibilities of the extension in [appendix A](#). We emphasize that such an extension does not affect our numerical results.

2.1 Mass spectrum of exotic particles

From the Lagrangian (2.1), the mass matrix for ψ_L and ψ_R is

$$-\frac{1}{2} \begin{pmatrix} \bar{\psi}_L & \bar{\psi}_R^c \end{pmatrix} \begin{pmatrix} m_{LL} & m_D \\ m_D & m_{RR} \end{pmatrix} \begin{pmatrix} \psi_L^c \\ \psi_R \end{pmatrix} + \text{h.c.} = -\frac{1}{2} \begin{pmatrix} \bar{\psi}_L & \bar{\psi}_R^c \end{pmatrix} \mathcal{M}_\psi \begin{pmatrix} \psi_L^c \\ \psi_R \end{pmatrix} + \text{h.c.}, \quad (2.6)$$

where \mathcal{M}_ψ is a complex symmetric matrix and diagonalized by a unitary matrix U_ψ :

$$\mathcal{M}_{\psi,\text{diag}} = U_\psi^\dagger \mathcal{M}_\psi U_\psi^*, \quad U_\psi = \begin{pmatrix} c_\alpha & s_\alpha e^{-i\tau} \\ -s_\alpha e^{i\tau} & c_\alpha \end{pmatrix}. \quad (2.7)$$

Here, $c_\alpha \equiv \cos \alpha$ with mixing angle α and τ is real. In our analysis, we take m_{LL} and m_{RR} to be real and positive, while m_D has a physical phase as $m_D = |m_D|e^{-i\theta_{\text{phys}}}$. We then obtain mass-squared eigenvalues of $\mathcal{M}_\psi^\dagger \mathcal{M}_\psi$ as

$$m_{\psi_1}^2 = \frac{1}{2} \left(m_{LL}^2 + m_{RR}^2 + 2|m_D|^2 - \Delta m_\psi^2 \right), \quad (2.8)$$

$$m_{\psi_2}^2 = \frac{1}{2} \left(m_{LL}^2 + m_{RR}^2 + 2|m_D|^2 + \Delta m_\psi^2 \right), \quad (2.9)$$

where $\Delta m_\psi^2 \equiv m_{\psi_2}^2 - m_{\psi_1}^2$ is given by

$$\Delta m_\psi^2 = \sqrt{(m_{LL}^2 - m_{RR}^2)^2 + 4|m_D|^2 \left| m_{LL}e^{-i\theta_{\text{phys}}} + m_{RR}e^{i\theta_{\text{phys}}} \right|^2}, \quad (2.10)$$

with θ_{phys} defined in Eq. (2.3). The mixing angle α and phase τ in U_ψ are obtained as

$$\sin 2\alpha = \frac{2|m_D|}{\Delta m_\psi^2} \left| m_{LL}e^{-i\theta_{\text{phys}}} + m_{RR}e^{i\theta_{\text{phys}}} \right|, \quad (2.11)$$

$$\tan \tau = -\frac{m_{LL} - m_{RR}}{m_{LL} + m_{RR}} \tan \theta_{\text{phys}}. \quad (2.12)$$

Due to the mass hierarchy, $m_{\psi_2}^2 > m_{\psi_1}^2$, we can focus on $0 \leq \alpha \leq \pi/2$. Note that physical predictions are unchanged for $\theta_{\text{phys}} \rightarrow \theta_{\text{phys}} + \pi$, and we focus on the range of $-\pi/2 < \theta_{\text{phys}} \leq \pi/2$ in our analysis. $\psi_{L,R}$ can be described in terms of mass eigenstates $\psi_{1,2}$ as

$$\psi_L = \psi_1^c c_\alpha + \psi_2^c s_\alpha e^{-i\tau}, \quad \psi_R = -\psi_1 s_\alpha e^{-i\tau} + \psi_2 c_\alpha, \quad (2.13)$$

and the mass terms in Eq. (2.6) become

$$-\frac{1}{2} \left[m_{\psi_1} \bar{\psi}_1^M \psi_1^M + m_{\psi_2} \bar{\psi}_2^M \psi_2^M \right], \quad (2.14)$$

where $\psi_{1,2}^M \equiv \psi_{1,2} + \psi_{1,2}^c$ are Majorana fermions.

In order to analyze the mass spectrum for exotic scalar fields, we parameterize them as

$$\phi = \begin{pmatrix} \phi^+ \\ \frac{1}{\sqrt{2}}(\sigma_\phi + ia_\phi) \end{pmatrix}, \quad \eta = \eta^+. \quad (2.15)$$

From Eq. (2.2), the mass-squared matrices for charged and neutral scalars (in the basis of (ϕ^+, η^+) and (σ_ϕ, a_ϕ) , respectively) are given by

$$\mathcal{M}_\pm^2 = \begin{pmatrix} M_\phi^2 & \frac{av_H}{\sqrt{2}} \\ \frac{av_H}{\sqrt{2}} & M_\eta^2 \end{pmatrix}, \quad (2.16)$$

$$\mathcal{M}_0^2 = \begin{pmatrix} M_\phi^2 + \frac{\lambda_{H\phi}^+}{2}v_H^2 & 0 \\ 0 & M_\phi^2 + \frac{\lambda_{H\phi}^-}{2}v_H^2 \end{pmatrix} \equiv \begin{pmatrix} m_{\sigma_\phi}^2 & 0 \\ 0 & m_{a_\phi}^2 \end{pmatrix}, \quad (2.17)$$

where $M_{\phi,\eta}^2 \equiv m_{\phi,\eta}^2 + \frac{\lambda_{H\phi,H\eta}}{2}v_H^2$ and $\lambda_{H\phi}^\pm \equiv \lambda'_{H\phi} \pm \lambda''_{H\phi}$. Note that since all quartic couplings are positive, $m_{a_\phi}^2$ is always smaller than $m_{\sigma_\phi}^2$. Diagonalization of \mathcal{M}_\pm^2 can be done by an orthogonal matrix as

$$\mathcal{M}_{\pm,\text{diag}}^2 = U_s^T \mathcal{M}_\pm^2 U_s, \quad U_s \equiv \begin{pmatrix} c_\theta & s_\theta \\ -s_\theta & c_\theta \end{pmatrix}. \quad (2.18)$$

The mass-squared eigenvalues and the mixing angle θ are

$$m_{\varphi_1^\pm}^2 = \frac{1}{2} \left[M_\phi^2 + M_\eta^2 - \sqrt{(M_\phi^2 - M_\eta^2)^2 + 2a^2v_H^2} \right], \quad (2.19)$$

$$m_{\varphi_2^\pm}^2 = \frac{1}{2} \left[M_\phi^2 + M_\eta^2 + \sqrt{(M_\phi^2 - M_\eta^2)^2 + 2a^2v_H^2} \right], \quad (2.20)$$

$$\sin 2\theta = \frac{\sqrt{2}av_H}{m_{\varphi_2^\pm}^2 - m_{\varphi_1^\pm}^2}. \quad (2.21)$$

Then, ϕ^\pm and η^\pm can be described in terms of mass eigenstates $\varphi_{1,2}^\pm$ as

$$\phi^\pm = \varphi_1^\pm c_\theta + \varphi_2^\pm s_\theta, \quad \eta^\pm = -\varphi_1^\pm s_\theta + \varphi_2^\pm c_\theta. \quad (2.22)$$

Since the mass parameter a can be set to be real and positive and $m_{\varphi_2^\pm}^2 - m_{\varphi_1^\pm}^2 > 0$, we can focus on $0 \leq \theta \leq \pi/2$.

2.2 Radiative mass and coupling of the muon

The mass and Yukawa coupling of the muon are induced by one-loop corrections. When we move to the mass basis for exotic particles according to Eqs. (2.13) and (2.22), the relevant terms are written as

$$\mathcal{L} \supset \left(-y_L^{ia} \bar{\mu}_L \varphi_i^- \psi_a - y_R^{ia} \bar{\psi}_a^c \varphi_i^+ \mu_R + \text{h.c.} \right) - \frac{A_{ij}}{\sqrt{2}} h^0 \varphi_i^- \varphi_j^+, \quad (2.23)$$

where the explicit forms of $y_{L,R}^{ia}$ and A_{ij} are summarized in Table 3. These couplings

(i, a)	y_L^{ia}	y_R^{ia}	(i, j)	A_{ij}
(1, 1)	$-y_\phi c_\theta s_\alpha e^{-i\tau}$	$-y_\eta s_\theta c_\alpha$	(1, 1)	$-a s_{2\theta} + \sqrt{2} v_H (\lambda_{H\phi} c_\theta^2 + \lambda_{H\eta} s_\theta^2)$
(1, 2)	$y_\phi c_\theta c_\alpha$	$-y_\eta s_\theta s_\alpha e^{i\tau}$	(1, 2)	$a c_{2\theta} + \sqrt{2} v_H (\lambda_{H\phi} - \lambda_{H\eta}) s_\theta c_\theta$
(2, 1)	$-y_\phi s_\theta s_\alpha e^{-i\tau}$	$y_\eta c_\theta c_\alpha$	(2, 1)	$a c_{2\theta} + \sqrt{2} v_H (\lambda_{H\phi} - \lambda_{H\eta}) s_\theta c_\theta$
(2, 2)	$y_\phi s_\theta c_\alpha$	$y_\eta c_\theta s_\alpha e^{i\tau}$	(2, 2)	$a s_{2\theta} + \sqrt{2} v_H (\lambda_{H\phi} s_\theta^2 + \lambda_{H\eta} c_\theta^2)$

Table 3: Yukawa couplings for the muon and exotic particles and scalar trilinear couplings in Eq. (2.23).

lead to the radiative mass and effective Yukawa coupling of the muon at the one-loop level, through diagrams in Fig. 1:

$$\mathcal{L}_{\text{eff}} \supset -m_\mu^{\text{rad}} \bar{\mu}_L \mu_R - \frac{y_\mu^{\text{eff}}}{\sqrt{2}} \bar{\mu}_L \mu_R h^0 + \text{h.c.}, \quad (2.24)$$

$$\begin{aligned} m_\mu^{\text{rad}} &= \sum_{i,a} \frac{y_L^{ia} y_R^{ia}}{16\pi^2} m_{\psi_a} \left(\frac{m_{\psi_a}^2 B_0(0, m_{\psi_a}^2, m_{\psi_a}^2) - m_{\varphi_i^+}^2 B_0(0, m_{\varphi_i^+}^2, m_{\varphi_i^+}^2)}{m_{\varphi_i^+}^2 - m_{\psi_a}^2} - 1 \right) \\ &= \frac{y_\phi y_\eta}{16\pi^2} \frac{s_{2\theta} s_{2\alpha}}{4} \mathcal{F}(x_{1,1}, x_{1,2}, x_{2,1}, x_{2,2}), \end{aligned} \quad (2.25)$$

$$y_\mu^{\text{eff}}(p_{h^0}^2) = - \sum_{i,j,a} \frac{y_L^{ia} y_R^{ja} A_{ij}}{16\pi^2} m_{\psi_a} C_0(m_\mu^2, m_\mu^2, p_{h^0}^2, m_{\varphi_i^+}^2, m_{\psi_a}^2, m_{\varphi_j^+}^2), \quad (2.26)$$

where p_{h^0} is the four-momentum of the SM Higgs boson, $m_{\psi_a} \equiv \sqrt{m_{\psi_a}^2}$, and $B_0(0, m^2, m^2)$ and $C_0(m_\mu^2, m_\mu^2, p_{h^0}^2, m_{\varphi_i^+}^2, m_{\psi_a}^2, m_{\varphi_j^+}^2)$ denote loop integrals for the self-energy and triangle type diagrams, respectively, whose explicit forms are summarized in Appendix B, and $\mathcal{F}(x_{1,1}, x_{1,2}, x_{2,1}, x_{2,2})$ is defined as

$$\mathcal{F}(x_{1,1}, x_{1,2}, x_{2,1}, x_{2,2}) \equiv -m_{\psi_1} e^{-i\tau} \left(\frac{x_{1,1}}{1 - x_{1,1}} \ln x_{1,1} - \frac{x_{2,1}}{1 - x_{2,1}} \ln x_{2,1} \right)$$

Figure 1: Feynman diagrams for (a) the effective Yukawa coupling of the muon and (b) dipole operators. The diagram for the radiative mass of the muon is obtained by eliminating the external photon line from the diagram (b).

$$+ m_{\psi_2} e^{i\tau} \left(\frac{x_{1,2}}{1-x_{1,2}} \ln x_{1,2} - \frac{x_{2,2}}{1-x_{2,2}} \ln x_{2,2} \right), \quad (2.27)$$

with $x_{i,a} \equiv m_{\varphi_i^+}^2/m_{\psi_a}^2$. Eq. (2.26) neglects sub-dominant contributions with a chirality flip on the muon line. We show the full form for y_μ^{eff} at the one-loop order in Appendix C. To numerically evaluate the loop functions with a non-zero $p_{h^0}^2$, we use `LoopTools` [39]. Note that due to the radiatively generated muon mass, there is no standard relation between m_μ^{rad} and y_μ^{eff} , namely, $m_\mu^{\text{rad}} \neq y_\mu^{\text{eff}} v_H/\sqrt{2}$. Hence, we need to check if the model satisfies a constraint from the measurement of $h \rightarrow \mu^+ \mu^-$. We discuss this constraint in Sec. 2.3.

Since m_μ^{rad} in Eq. (2.25) generally has a phase due to complex couplings $y_{L,R}^{ia}$, we need to remove it by a chiral rotation of the muon field as

$$\mu \rightarrow e^{-i\theta_\mu \gamma_5/2} \mu, \quad (2.28)$$

where θ_μ is defined as $m_\mu^{\text{rad}} = m_\mu e^{i\theta_\mu}$. Here, m_μ is understood as the observed muon mass and a real value, and θ_μ can be obtained as $\theta_\mu = \arg[\mathcal{F}(x_{1,1}, x_{1,2}, x_{2,1}, x_{2,2})]$. This rotation affects dipole operators,

$$\mathcal{L}_{\text{dipole}} = -\frac{e}{2} C_T(q^2) (\bar{\mu} \sigma^{\alpha\beta} \mu) F_{\alpha\beta} - \frac{e}{2} C_{T'}(q^2) (\bar{\mu} i \sigma^{\alpha\beta} \gamma_5 \mu) F_{\alpha\beta}, \quad (2.29)$$

where q is the four-momentum for the photon. If there was no chiral rotation, $C_T(0)$ and $C_{T'}(0)$ would be the muon $g-2$ a_μ and the muon EDM d_μ , respectively. After performing the chiral rotation of Eq. (2.28), we can obtain the correct forms of a_μ and d_μ in our model as

$$\mathcal{L}_{\text{dipole}} = -\frac{e}{4m_\mu} a_\mu (\bar{\mu} \sigma^{\alpha\beta} \mu) F_{\alpha\beta} - \frac{i}{2} d_\mu (\bar{\mu} \sigma^{\alpha\beta} \gamma_5 \mu) F_{\alpha\beta}, \quad (2.30)$$

$$a_\mu = 2m_\mu (C_T(0) \cos \theta_\mu + C_{T'}(0) \sin \theta_\mu) , \quad (2.31)$$

$$d_\mu = e (C_{T'}(0) \cos \theta_\mu - C_T(0) \sin \theta_\mu) . \quad (2.32)$$

The leading contributions to $C_T(0)$ and $C_{T'}(0)$ can be estimated from the diagram (b) in Fig. 1 as

$$C_T(0) = \sum_{i,a} \frac{\text{Re}[y_L^{ia} y_R^{ia}]}{16\pi^2} m_{\psi_a} \left[C_0(m_{\psi_a}^2, m_{\varphi_i^+}^2) + 2C_1(m_{\psi_a}^2, m_{\varphi_i^+}^2) \right] , \quad (2.33)$$

$$C_{T'}(0) = \sum_{i,a} \frac{\text{Im}[y_L^{ia} y_R^{ia}]}{16\pi^2} m_{\psi_a} \left[C_0(m_{\psi_a}^2, m_{\varphi_i^+}^2) + 2C_1(m_{\psi_a}^2, m_{\varphi_i^+}^2) \right] , \quad (2.34)$$

where

$$C_0(m_{\psi_a}^2, m_{\varphi_i^+}^2) \equiv C_0(m_\mu^2, m_\mu^2, 0, m_{\varphi_i^+}^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) \approx C_0(0, 0, 0, m_{\varphi_i^+}^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) , \quad (2.35)$$

$$C_1(m_{\psi_a}^2, m_{\varphi_i^+}^2) \equiv C_1(m_\mu^2, 0, m_\mu^2, m_{\psi_a}^2, m_{\varphi_i^+}^2, m_{\varphi_i^+}^2) \approx C_1(0, 0, 0, m_{\psi_a}^2, m_{\varphi_i^+}^2, m_{\varphi_i^+}^2) , \quad (2.36)$$

are loop integrals for the triangle type diagram, and approximations in the right hand sides are valid when $m_\mu^2 \ll m_{\varphi_i^+}^2, m_{\psi_a}^2$. In this case, we can obtain the following analytical forms of C_0 and C_1 :

$$C_0(0, 0, 0, m_{\varphi_i^+}^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) = \frac{1}{m_{\psi_a}^2} \left[\frac{1}{1 - x_{i,a}} + \frac{1}{(1 - x_{i,a})^2} \ln x_{i,a} \right] , \quad (2.37)$$

$$C_1(0, 0, 0, m_{\varphi_i^+}^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) = -\frac{1}{m_{\psi_a}^2} \left[\frac{3 - x_{i,a}}{4(1 - x_{i,a})^2} + \frac{1}{2(1 - x_{i,a})^3} \ln x_{i,a} \right] . \quad (2.38)$$

Here, $x_{i,a}$ is defined below Eq. (2.27). Since the leading contributions to $C_T(0)$ and $C_{T'}(0)$ are the same except for the overall couplings, $\text{Re}[y_L^{ia} y_R^{ia}]$ and $\text{Im}[y_L^{ia} y_R^{ia}]$, we can expect a sufficiently large d_μ to be probed in near-future experiments when the muon $g - 2$ is predicted to be $\mathcal{O}(10^{-9})$. That is, when $C_T(0) \cos \theta_\mu + C_{T'}(0) \sin \theta_\mu \sim C_{T'}(0) \cos \theta_\mu - C_T(0) \sin \theta_\mu$ is satisfied, we find

$$d_\mu \sim \frac{e}{2m_\mu} \times a_\mu \simeq 2.34 \times 10^{-22} e \text{ cm} , \quad (2.39)$$

with $a_\mu \simeq 2.51 \times 10^{-9}$. By using couplings in Table. 3 and Eqs. (2.25), (2.37) and (2.38), $C_T(0)$ and $C_{T'}(0)$ can be rewritten as

$$C_T(0) = \frac{m_\mu \cos \tau}{|\mathcal{F}(x_{1,1}, x_{1,2}, x_{2,1}, x_{2,2})|} \sum_{i,a=1}^2 \frac{(-1)^{i+a}}{m_{\psi_a}} \frac{x_{i,a}^2 - 1 - 2x_{i,a} \ln x_{i,a}}{2(1 - x_{i,a})^3} , \quad (2.40)$$

$$C_{T'}(0) = \frac{m_\mu \sin \tau}{|\mathcal{F}(x_{1,1}, x_{1,2}, x_{2,1}, x_{2,2})|} \sum_{i,a=1}^2 \frac{(-1)^i}{m_{\psi_a}} \frac{x_{i,a}^2 - 1 - 2x_{i,a} \ln x_{i,a}}{2(1 - x_{i,a})^3} . \quad (2.41)$$

As $|\mathcal{F}|$ is proportional to $m_{\psi_{1,2}}$, their scalings are consistent with the rough estimation given in Eq. (1.3). It is notable that when we change $\theta_{\text{phys}} \rightarrow -\theta_{\text{phys}}$, signs of $\sin \tau$ and $\sin \theta_\mu$ are flipped, the former of which leads to $C_{T'}(0) \rightarrow -C_{T'}(0)$ through Eq. (2.41), and hence, this change results in $d_\mu \rightarrow -d_\mu$ with a_μ unchanged. This fact tells us that it is enough to focus on the range $0 < \theta_{\text{phys}} < \pi/2$, because we are only interested in the prediction of $|d_\mu|$ here. Furthermore, $\theta_{\text{phys}} = 0$ corresponds to a CP conserving limit which gives $|d_\mu| = 0$, while $\theta_{\text{phys}} = \pi/2$ leads to $\tau \approx \pi/2$ unless $m_{LL} = m_{RR}$ (see Eq. (2.12)), predicting $\cos \theta_\mu \approx 0$, and hence, $|d_\mu| \propto C_{T'}(0) \cos \theta_\mu - C_T(0) \sin \theta_\mu \approx 0$. Hereafter, we denote d_μ as its absolute value $|d_\mu|$ in our analysis.

2.3 Muon coupling constraints

In our model, the muon Yukawa coupling to the Higgs boson is generated at the one-loop level and does not follow the standard relation, $m_\mu^{\text{rad}} \neq y_\mu^{\text{eff}} v_H / \sqrt{2}$. The ATLAS [40] and CMS [41] experiments have searched for the Higgs boson decay $h \rightarrow \mu^+ \mu^-$, which lead to constraints on the h - μ - μ coupling as

$$|\kappa_\mu| < 1.47 \quad (\text{ATLAS}), \quad (2.42)$$

$$0.61 < |\kappa_\mu| < 1.44 \quad (\text{CMS}), \quad (2.43)$$

where we use $\text{BR}(h \rightarrow \mu^+ \mu^-)_{\text{SM}} \simeq 2.16 \times 10^{-4}$ for $m_h = 125.25$ GeV [42], and κ_μ is defined by comparing the decay width of $h \rightarrow \mu^+ \mu^-$ to that of the SM,

$$\Gamma_{h \rightarrow \mu^+ \mu^-}^{\text{SM}} = \frac{m_h}{8\pi} \left(\frac{m_\mu}{v_H} \right)^2 \left(1 - \frac{4m_\mu^2}{m_h^2} \right)^{3/2}. \quad (2.44)$$

In our model, the width of $h \rightarrow \mu^+ \mu^-$ is estimated as

$$\Gamma_{h \rightarrow \mu^+ \mu^-} = \frac{m_h}{16\pi} \sqrt{1 - \frac{4m_\mu^2}{m_h^2}} \left[\left(1 - \frac{4m_\mu^2}{m_h^2} \right) (\text{Re } y_\mu^{\text{eff}})^2 + (\text{Im } y_\mu^{\text{eff}})^2 \right]. \quad (2.45)$$

Then, we find

$$|\kappa_\mu| = \frac{1}{\sqrt{2}} \frac{v_H}{m_\mu} \sqrt{(\text{Re } y_\mu^{\text{eff}})^2 + \left(1 - \frac{4m_\mu^2}{m_h^2} \right)^{-1} (\text{Im } y_\mu^{\text{eff}})^2} \approx \frac{1}{\sqrt{2}} \frac{v_H}{m_\mu} |y_\mu^{\text{eff}}|. \quad (2.46)$$

Here, we have used $4m_\mu^2 \ll m_h^2$.

Since exotic particles exclusively couple to the muon, the ratio between the $Z \rightarrow e^+ e^-$ and $Z \rightarrow \mu^+ \mu^-$ decay widths may constrain our parameter space. The current

experimental status for this ratio is [43]

$$\frac{\Gamma(Z \rightarrow \mu^+ \mu^-)}{\Gamma(Z \rightarrow e^+ e^-)} = 1.0009 \pm 0.0028. \quad (2.47)$$

The muon couplings to the Z boson can be parameterized as

$$\mathcal{L}_Z \supset \frac{g}{\cos \theta_W} \bar{\mu} \gamma^\alpha \left[(g_L^\mu + \delta g_L^\mu) P_L + (g_R^\mu + \delta g_R^\mu) P_R \right] \mu Z_\alpha, \quad (2.48)$$

where g denotes the $SU(2)_L$ gauge coupling, θ_W is the weak mixing angle, and $g_L^\mu = -\frac{1}{2} + \sin^2 \theta_W$, and $g_R^\mu = \sin^2 \theta_W$ are the muon couplings to the Z boson in the SM. In our model, new physics contributions $\delta g_{L,R}$ are induced by the diagram (b) in Fig. 1 with replacing the photon to the Z boson, and their expressions are found in ref. [44]. The ratio in Eq. (2.47) is then estimated as

$$\frac{\Gamma(Z \rightarrow \mu^+ \mu^-)}{\Gamma(Z \rightarrow e^+ e^-)} \simeq 1 + \frac{2g_L^e \text{Re}(\delta g_L^\mu) + 2g_R^e \text{Re}(\delta g_R^\mu)}{(g_L^e)^2 + (g_R^e)^2} \equiv 1 + \delta_{\mu\mu}, \quad (2.49)$$

where $g_{L,R}^e = g_{L,R}^\mu$ are the electron couplings to the Z boson in the SM, and we assume that new physics contributions are smaller than those of the SM, $\delta g_{L,R}^\mu \ll g_{L,R}^\mu$. Then, Eq. (2.47) indicates that $|\delta_{\mu\mu}|$ must be less than $\mathcal{O}(10^{-3})$.

3 Dark matter

The candidate of DM in our model is the lightest Majorana fermion ψ_1^M or the lightest neutral scalar a_ϕ , depending on their masses. In the present paper, we focus on the case that ψ_1^M is the lightest exotic particle, and hence, gives the DM candidate. Hereafter, we denote ψ_1^M as ψ_1 for simplicity. For the case that a_ϕ is the DM candidate, there is no direct correlation with the muon EDM, because the mass m_{a_ϕ} does not contribute to the muon EDM at the one-loop level.

The main annihilation mode of the DM fermion is $\psi_1 \psi_1 \rightarrow \mu \bar{\mu}$ through the t -channel exchange of φ_i^\pm , as shown in the left of Fig. 2. In the expansion of the thermally averaged cross section by the DM velocity v , $\langle \sigma v \rangle_{\mu\bar{\mu}} = a_{\mu\bar{\mu}} + b_{\mu\bar{\mu}} v^2 + \mathcal{O}(v^4)$, s -wave and p -wave contributions are given by

$$a_{\mu\bar{\mu}} = \frac{1}{16\pi m_{\psi_1}^2} \left[\left| \sum_{i=1,2} \frac{y_L^{i1} y_R^{i1}}{1 + x_{i,1}} \right|^2 + \mathcal{O} \left(\frac{m_\mu^2}{m_{\psi_1}^2} \right) \right], \quad (3.1)$$

$$b_{\mu\bar{\mu}} = \frac{1}{48\pi m_{\psi_1}^2} \left(\sum_{i=1,2} \frac{|y_L^{i1}|^2}{(1 + x_{i,1})^2} \sqrt{1 + x_{i,1}^2} \right)^2 + (L \rightarrow R), \quad (3.2)$$

Figure 2: Feynman diagrams for DM self-annihilation (left), DM-charged scalar coannihilation (center) and charged scalar self-annihilation (right). V denotes the γ/Z boson. Other diagrams can be obtained by changing final states with an appropriate mediator.

where the second term in Eq. (3.1) is suppressed by m_μ/m_{ψ_1} . Thus, the s -wave contribution dominates the total DM annihilation cross section in our focused parameter space. Note that for the annihilation mode $\psi_1\bar{\psi}_1 \rightarrow \nu_\mu\bar{\nu}_\mu$, the s -wave contribution is suppressed by a tiny neutrino mass, because there is no right-handed coupling y_R^{i1} for the neutrino. The other annihilation cross sections, such as $\psi_1\bar{\psi}_1 \rightarrow \gamma\gamma$ and $\psi_1\bar{\psi}_1 \rightarrow \mu\bar{\mu}\gamma$, are several orders of magnitude smaller than that of $\psi_1\bar{\psi}_1 \rightarrow \mu\bar{\mu}$.

In the thermal freeze-out scenario, the number density of DM is calculated by the Boltzmann equation,

$$\frac{dn_{\psi_1}(t)}{dt} + 3H(t)n_{\psi_1}(t) = -\langle\sigma v\rangle_{\text{eff}} \left[n_{\psi_1}(t)^2 - n_{\psi_1}^{\text{eq}}(t)^2 \right]. \quad (3.3)$$

Here, $H(t)$ denotes the Hubble rate, and n_{ψ_1} is the number density of ψ_1 , while $n_{\psi_1}^{\text{eq}}$ is that in equilibrium. The effective annihilation cross section $\langle\sigma v\rangle_{\text{eff}}$ is estimated by summing all possible annihilation modes, i.e., $\psi_1\bar{\psi}_1 \rightarrow \ell\bar{\ell}, VV', \ell\bar{\ell}V$ ($\ell = \mu, \nu$; $V, V' = \gamma, Z, W$). However, when the DM and charged scalar masses are almost degenerate, coannihilation processes should be taken into account for solving the Boltzmann equation. In this case, we have [45]

$$(\sigma v)_{\text{eff}} = \frac{1}{(g_{\psi_1} + \bar{g}_{\varphi_1^+})^2} \left[g_{\psi_1}^2 (\sigma v)_{\psi_1\bar{\psi}_1} + g_{\psi_1} \bar{g}_{\varphi_1^+} (\sigma v)_{\psi_1\varphi_1^+} + \bar{g}_{\varphi_1^+}^2 (\sigma v)_{\varphi_1^+\varphi_1^-} \right], \quad (3.4)$$

$$\text{with } \bar{g}_{\varphi_1^+} = g_{\varphi_1^+} \left(\frac{m_{\varphi_1^+}}{m_{\psi_1}} \right)^{3/2} e^{-(m_{\varphi_1^+} - m_{\psi_1})/T}, \quad (3.5)$$

where $g_{\psi_1} = 2$ and $g_{\varphi_1^+} = 2$ are internal degrees of freedom for ψ_1 and φ_1^+ , respectively, T is the temperature, and $(\sigma v)_{XY}$ denotes the (co)annihilation cross section whose initial state is XY . The corresponding diagrams are shown in Fig. 2. The second term in Eq. (3.4) is suppressed by the exponential factor in Eq. (3.5) and the third term is more suppressed due to the squared exponential factor when $m_{\varphi_1^+} \gg m_{\psi_1}$. As $m_{\varphi_1^+}$ decreases and is close to m_{ψ_1} , the second term gives a non-negligible contribution to $(\sigma v)_{\text{eff}}$ [46, 47].

The resultant DM relic density is given by

$$\Omega h^2 = \frac{m_{\psi_1} n_{\psi_1}(t_0)}{\rho_c} h^2, \quad (3.6)$$

where ρ_c is the critical density of the Universe and $n_{\psi_1}(t_0)$ is the today's number density of ψ_1 obtained by solving the Boltzmann equation (3.3). To calculate the DM relic density Ωh^2 including appropriate coannihilation processes, we use `micrOMEGAs_5.2.13` [48, 49].

Although our DM particle ψ_1 does not couple to the SM quarks and gluons, the DM-nucleon scattering is induced by contact and non-contact type interactions. In our model, relevant interactions for the scattering are

$$\mathcal{L}_{\text{eff}} \supset a_{\psi_1} \bar{\psi}_1 \gamma^\mu \gamma^5 \psi_1 \partial^\nu F_{\mu\nu} + C_{S,p} \bar{\psi}_1 \psi_1 \bar{p} p + C_{S,n} \bar{\psi}_1 \psi_1 \bar{n} n. \quad (3.7)$$

Here, p and n represent the proton and the neutron, and the effective coefficients are estimated as

$$a_{\psi_1} = -\frac{e}{16\pi^2 m_{\psi_1}^2} \sum_{i=1,2} \left(|y_L^{i1}|^2 + |y_R^{i1}|^2 \right) \hat{a}_{\psi_1}(x_{i,1}, \epsilon_\mu), \quad (3.8)$$

$$C_{S,N} = -m_N \sum_q C_{S,q} \frac{f_{Tq}^{(N)}}{m_q} = -\frac{y_{\psi_1}^{\text{eff}} m_N}{\sqrt{2} m_h^2 v_H} \sum_q f_{Tq}^{(N)} \quad (N = p, n), \quad (3.9)$$

where $x_{i,1}$ is defined below Eq. (2.27), $\epsilon_\mu \equiv m_\mu^2/m_{\psi_1}^2$, $\hat{a}_{\psi_1}(x, y)$ is the loop function for the anapole operator, which is given by

$$\hat{a}_{\psi_1}(x, y) = \frac{1}{12} \left[\frac{3}{2} \ln \left(\frac{y}{x} \right) + \frac{3x - 3y + 1}{\Delta(x, y)^{1/2}} \tanh^{-1} \left(\frac{\Delta(x, y)^{1/2}}{x + y - 1} \right) \right], \quad (3.10)$$

with $\Delta(x, y) = x^2 + (y-1)^2 - 2x(y+1)$, $C_{S,q}$ denotes the effective coupling of an operator $\bar{\psi}_1 \psi_1 \bar{q} q$ with the SM quark q , and $f_{Tq}^{(N)}$ is related to the quark mass contribution to the nucleon mass, whose value can be found in refs. [50–59]. $y_{\psi_1}^{\text{eff}}$ is the effective Yukawa coupling of ψ_1 , and it can be obtained by the replacement of $m_{\psi_1} \leftrightarrow m_\mu$ and $y_L \leftrightarrow y_R$ in the expression of y_μ^{eff} given in Eq. (C.1). This effective Yukawa coupling increases when m_{ψ_1} becomes large, because it is proportional to m_{ψ_1} like y_μ^{eff} (see Eq. (2.26)). The function $\hat{a}_{\psi_1}(x, y)$ is enhanced when $x \rightarrow 1$ with $y \neq 0$. Therefore, the limit of $m_{\psi_1} \simeq m_{\varphi_1^+}$ leads to a large contribution to the cross section from a_{ψ_1} . Note that for the Majorana DM model, there are other contributions through the Z -penguin which lead to effective interactions such as $(\bar{\psi}_1 \gamma^\mu \gamma^5 \psi_1)(\bar{q} \gamma_\mu q)$ and $(\bar{\psi}_1 \gamma^\mu \gamma^5 \psi_1)(\bar{q} \gamma_\mu \gamma^5 q)$. However, these contributions are suppressed by the lepton mass (and the DM velocity for the former

interaction), and we neglect their effects in our analysis. Using the effective couplings in Eq. (3.7), the differential cross section with respect to the recoil energy E_R is estimated as

$$\begin{aligned} \frac{d\sigma}{dE_R} = & \left\{ \frac{2m_N f_A^2}{\pi v^2} + \frac{4\alpha Z^2}{v^2} a_{\psi_1}^2 \left[2m_N v^2 - \frac{(m_N + m_{\psi_1})^2}{m_{\psi_1}^2} E_R \right] \right\} |F_{\text{Helm}}(E_R)|^2 \\ & + \frac{8m_N^2 \mu_A^2}{\pi v^2} E_R a_{\psi_1}^2 \frac{J_A + 1}{3J_A} |F_{\text{spin}}(E_R)|^2, \end{aligned} \quad (3.11)$$

where v is the DM velocity, α is the fine structure constant, $f_A = ZC_{S,p} + (A-Z)C_{S,n}$ with an atomic number Z and a mass number A , and m_N , μ_A and J_A are the mass, magnetic moment and spin of the nucleus, respectively. $F_{\text{Helm}}(E_R)$ and $F_{\text{spin}}(E_R)$ denote form factors found in refs. [60, 61]. It can be seen from Eq. (3.11) that the anapole contribution is suppressed by the DM velocity v or the recoil energy E_R . On the other hand, there is no suppression for contributions from the contact-type interactions. It is notable that in our model, $C_{S,N}$ in f_A is enhanced by $y_{\psi_1}^{\text{eff}}$ due to the absence of the tree-level muon Yukawa coupling. Recently, the LUX-ZEPLIN (LZ) experiment has reported their first results for spin-independent (SI) and spin-dependent (SD) DM-nucleon scattering cross sections [62]. The upper limit on the SI cross section has been improved, compared with previous results from the XENON1T [63, 64] and PandaX-4T [65, 66] experiments. The corresponding cross sections in our model are given by [50, 67, 68]

$$\sigma_{\text{SI}}^{\text{scalar}} = \frac{4\mu_N^2 |y_{\psi_1}^{\text{eff}}|^2 m_N^2}{\pi 2m_h^4 v_H^2} \left(\sum_q f_{Tq}^{(N)} \right)^2, \quad (3.12)$$

$$\sigma_{\text{SI}}^{\text{anapole}} = 8\alpha |a_{\psi_1}|^2 \mu_N^2 v^2. \quad (3.13)$$

Here, μ_N is the reduced mass for m_{ψ_1} and the nucleon mass $\simeq 0.939$ GeV.

4 Numerical analysis

In this section, we first summarize the independent parameters in our model. Then, the parameter space that gives the correct DM relic density and explains the muon $g - 2$ anomaly is identified and the size of the muon EDM is indicated in that region as well as more general parameter regions. We take account of muon coupling constraints presented in section 2.3 and also discuss constraints from DM direct and indirect detection experiments as well as collider searches.

4.1 Independent parameters

The Lagrangian of our model contains 18 parameters,

$$\begin{aligned} & y_\phi, y_\eta, |m_D|, |m_{LL}|, |m_{RR}|, \theta_{\text{phys}}, \\ & m_H^2, m_\phi^2, m_\eta^2, a, \lambda_H, \lambda_\phi, \lambda_\eta, \lambda_{H\phi}, \lambda_{H\eta}, \lambda_{\phi\eta}, \lambda'_{H\phi}, \lambda''_{H\phi}. \end{aligned} \quad (4.1)$$

Note that some of them are irrelevant to our analysis on the calculation of the muon $g - 2$, the muon EDM, the radiative mass, and the effective Yukawa coupling of the muon. The Higgs mass-squared parameter m_H^2 is fixed by the minimization condition in Eq. (2.5), and λ_H should be determined so that the SM Higgs mass, $m_h = 125.25$ GeV, is correctly reproduced. The quartic couplings λ_ϕ , λ_η and $\lambda_{\phi\eta}$ are irrelevant to the mass spectrum of exotic particles, although these values should be consistent with perturbative unitarity bounds (commented below) and also chosen to avoid an unstable minimum of the scalar potential. Moreover, $y_\phi y_\eta$ can be fixed by using Eq. (2.25), but we need to check that values of the couplings do not exceed $\sqrt{4\pi}$. As a result, the relevant (and independent) input parameters for the analysis can be read as

$$y_\phi, |m_D|, |m_{LL}|, |m_{RR}|, \theta_{\text{phys}}, m_\phi^2, m_\eta^2, a, \lambda_{H\phi}, \lambda'_{H\phi}, \lambda''_{H\phi}, \lambda_{H\eta}. \quad (4.2)$$

Note that $\lambda'_{H\phi}$ and $\lambda''_{H\phi}$ are relevant only to the masses of heavy neutral scalars, $m_{\sigma_\phi}^2$ and $m_{a_\phi}^2$ (see Eq. (2.17)), and irrelevant to our following analysis as long as the DM candidate of the model is ψ_1 . Furthermore, we discuss our results by using M_ϕ^2 and M_η^2 instead of $m_\phi^2, m_\eta^2, \lambda_{H\phi}$ and $\lambda_{H\eta}$ (see below Eq. (2.17)).

We here comment on perturbative unitarity bounds [69, 70], which are related to $2 \rightarrow 2$ scattering processes of scalar particles. At the tree level, it is clear that quartic couplings are related to their amplitudes. In addition, trilinear couplings also contribute to them through s -, t - and u -channel processes if scalar particles are not so heavy. There are studies on the bounds, e.g., for models extended by singlet scalars [71–73] and doublet scalars [74–80]. Since our model is a hybrid extension with one singlet and one doublet scalars, there are lots of scattering processes like $hh \rightarrow \sigma_\phi \sigma_\phi$, $h\sigma_\phi \rightarrow \varphi_i^+ \varphi_j^-$ and $\varphi_i^+ \varphi_j^- \rightarrow a_\phi a_\phi$. To obtain perturbative unitarity bounds in our model, we use the SARAH/SPheno framework [81–87]. The details of the calculation for general scalar couplings can be found in ref. [88].

Figure 3: The predictions of $(g-2)_\mu$ and the muon EDM d_μ in terms of m_{ψ_1} and $m_{\phi_1^+}$. We fix the model parameters as follows: $y_\phi = 1.2$, $m_D = 700$ GeV, $m_{RR} = 1000$ GeV, $\theta_{\text{phys}} = 1.0$, $M_\phi^2 = (1000 \text{ GeV})^2$, $a = 900$ GeV. m_{LL} and M_η^2 are changed as $320 \text{ GeV} \leq m_{LL} \leq 1200 \text{ GeV}$ and $(540 \text{ GeV})^2 \leq M_\eta^2 \leq (1000 \text{ GeV})^2$, respectively. Green and yellow shaded regions denote 1σ and 2σ bands for $(g-2)_\mu$, and black lines correspond to contours for d_μ in $10^{-23} e \text{ cm}$ unit. The future prospects of the Fermilab Muon $g-2$ [8] and J-PARC Muon $g-2$ /EDM [9] experiments are shown as the orange shaded region. The red band is the correct DM relic density, $\Omega h^2 = 0.120 \pm 0.001$, and contours for $\Omega h^2 = 0.5$ and 1.0 are shown in blue and turquoise lines, respectively. The dot-dashed magenta lines correspond to $\kappa_\mu = 0.996$ and 1.004 . The dashed gray line gives $m_{\psi_1} = m_{\phi_1^+}$.

4.2 Results

Fig. 3 shows the predictions of $(g-2)_\mu$ and the muon EDM d_μ in our model. Here, we fix the relevant parameters as ⁵

$$\begin{aligned} y_\phi &= 1.2, \quad M_\phi^2 = (1000 \text{ GeV})^2, \quad a = 900 \text{ GeV}, \\ m_D &= 700 \text{ GeV}, \quad m_{RR} = 1000 \text{ GeV}, \quad \theta_{\text{phys}} = 1.0, \end{aligned} \quad (4.3)$$

⁵If we change m_{RR} instead of m_{LL} and set $m_{LL} = 1000$ GeV, the prediction for d_μ is totally the same as that of Fig. 3, because the mass eigenvalues of $\psi_{1,2}$ and the mixing angle α are symmetric under $m_{LL} \leftrightarrow m_{RR}$. Although $\tan \tau$ changes its sign, it is irrelevant to the absolute value of d_μ .

and change m_{LL} and M_η^2 as $320 \text{ GeV} \leq m_{LL} \leq 1200 \text{ GeV}$ and $(540 \text{ GeV})^2 \leq M_\eta^2 \leq (1000 \text{ GeV})^2$, respectively. For this parameter choice, the lightest particle among X -odd particles is either ψ_1 or φ_1^+ . The other parameters which are not shown in Eq. (4.2), i.e. scalar quartic couplings, does not affect the analysis here and are taken to be moderate values to satisfy perturbative unitarity bounds. Note that when the scalar trilinear coupling a becomes large, some of the quartic couplings should be $\mathcal{O}(1)$ to avoid the instability of the vacuum to give the correct electroweak symmetry breaking. We numerically check that the SM vacuum is stable when all of quartic couplings are within the range of 0.2-0.5 with the parameter choice shown above. These values of quartic couplings also satisfy perturbative unitarity bounds, which is checked by the SARAH/SPheno framework. In addition, since we have an additional $SU(2)_L$ doublet scalar, there is a new contribution to the T -parameter [89, 90]. We have calculated the contribution by following refs. [91, 92] and found that our parameter choice leads to $\Delta T \sim 0.002$, which satisfies the current constraint [93].

The current discrepancy of $(g-2)_\mu$ is [1–4]

$$\Delta a_\mu = (2.51 \pm 0.59) \times 10^{-9}, \quad (4.4)$$

whose 1σ and 2σ bands are shown as green and yellow shaded regions in Fig. 3. Note that a lighter m_{ψ_1} predicts a larger Δa_μ due to its dependence, $\Delta a_\mu \sim 1/m_{\psi_1}^2$. In the figure, black lines correspond to contours for d_μ in 10^{-23} e cm unit. The future prospect of the muon EDM, which is reported as $\mathcal{O}(10^{-21}) \text{ e cm}$ at the Fermilab Muon $g-2$ experiment [8] and the J-PARC Muon $g-2/\text{EDM}$ experiment [9], is shown as the orange shaded region. The red band shows the parameter space where the correct DM relic density, $\Omega h^2 = 0.120 \pm 0.001$ [94], is obtained. Outside of this band, the relic density changes rapidly, as one can see from the blue and turquoise contours which correspond to $\Omega h^2 = 0.5$ and 1.0 , respectively. Note that in the whole parameter space of Fig. 3, a new physics contribution to the ratio between the decay widths of $Z \rightarrow e^+e^-$ and $Z \rightarrow \mu^+\mu^-$ in Eq. (2.49) is sufficiently small, and we obtain $|\delta_{\mu\mu}| \lesssim 4 \times 10^{-4}$ which is consistent with the current data (2.47).

For the case of $m_{\psi_1} > m_{\varphi_1^+}$ (the region below the dashed gray line), the $\psi_1 \rightarrow \varphi_1^\pm + \mu^\mp$ decay occurs at the tree level, and therefore, ψ_1 cannot be a DM candidate⁶. Without any interaction to break the exotic number symmetry X , φ_1^+ is a stable exotic particle, which may be cosmologically dangerous. However, we can consider, for example, an interaction with the right-handed electron, $\overline{L}_L^\mu \phi^\dagger e_R$, to make φ_1^+ decay into $\nu_\mu + e^+$ ⁷.

⁶Since $m_{\psi_1} < m_{\sigma_\phi, a_\phi}$ in the current input parameters (see Eqs. (2.17) and (4.3)), the DM cannot decay into $\nu_\mu + \sigma_\phi$, $\nu_\mu + a_\phi$ in the plotted region of Fig. 3.

⁷This lepton flavor violating (LFV) interaction does not induce LFV processes such as $\mu \rightarrow e\gamma$

Interestingly, the parameter region predicts a large d_μ due to a small value of $m_{\varphi_1^+}$ and may be also explored by Higgs coupling measurements at future collider experiments. Ref. [100] summarizes future sensitivities for the measurements of the SM Higgs couplings. In particular, the Future Circular Collider (FCC) may be able to measure κ_μ with relative precision of $\sim 0.4\%$ whose contours are shown as dot-dashed magenta lines in Fig. 3⁸.

In the whole parameter region shown in the figure, the muon EDM is predicted to be larger than the future sensitivity of the PSI muEDM experiment, $6 \times 10^{-23} e \text{ cm}$ [10–12]. The 2σ discrepancy of $(g-2)_\mu$ can be explained for $560 \text{ GeV} < m_{\psi_1} < 780 \text{ GeV}$, while only the region of $m_{\psi_1} \simeq m_{\varphi_1^+}$ is favored for the correct DM relic density. With the current parameter choice, the coannihilation process plays an important role in obtaining the correct relic density.

For $m_{\psi_1} \simeq 850\text{--}860 \text{ GeV}$, the DM sector contribution to the muon EDM accidentally disappears. This behavior can be understood as follows. In this region, $m_{LL} \simeq 1000 \text{ GeV}$ which means $m_{LL} \simeq m_{RR}$ for our current setup. Eq. (2.12) tells us that $\theta_{\text{phys}} = 0$ or $|m_{LL}| = |m_{RR}|$ can lead to $\tan \tau = 0$, which makes y_L^{ia} and y_R^{ia} real. Therefore, there is no contribution to the muon EDM for $|m_{LL}| = |m_{RR}|$, even when the physical phase has a non-zero value, $\theta_{\text{phys}} \neq 0$.

We now comment on constraints from DM searches at colliders and DM direct and indirect detection experiments.

1. Collider searches

At the Large Hadron Collider (LHC), we expect a pair production of exotic charged scalars φ_1 decaying into muons and DM fermions:

$$pp \rightarrow \varphi_1 \varphi_1 \rightarrow \mu\mu + \psi_1 \psi_1, \quad (4.5)$$

whose signal is two muons plus a large missing energy. The signal is similar to that of a pair production of sleptons decaying into leptons and a missing energy. Then, the ATLAS [101, 102] and CMS [103] experiments put a lower bound on the DM mass. However, it is less than 500 GeV [101], which is outside the plot range of Fig. 3. Ref. [104] has performed the numerical analysis to obtain a bound on the DM mass for the similar model, and it was found to be $200\text{--}300 \text{ GeV}$, depending on the size of the mixing angle s_θ in Eq. (2.18) and the mass of φ_1^+ . Ref. [102] has

because of the muon number symmetry L_μ . However, the interaction with a sizable coupling may be constrained by the muonium-antimuonium oscillation [95–99] although we do not need a large coupling for our purpose.

⁸Here, we just assume that the central value of κ_μ is 1 at future collider experiments.

investigated the case with $m_{\psi_1} \sim m_{\varphi_1^+}$ and put a lower bound on $m_{\varphi_1^+}$ less than 250 GeV for $m_{\varphi_1^+} - m_{\psi_1} = \mathcal{O}(10)$ GeV.

2. Indirect detection

As mentioned in Sec. 3, the annihilation cross section of our DM ψ_1 is dominated by $\psi_1\psi_1 \rightarrow \mu\bar{\mu}$. For the parameter region in Fig. 3, we obtain the prediction of $\langle\sigma v\rangle_{\mu\bar{\mu}} \simeq \mathcal{O}(10^{-27})\text{--}\mathcal{O}(10^{-28})\text{ cm}^3/\text{s}$. Ref. [105] has studied a constraint on the annihilation cross section of a Majorana DM, whose annihilation modes are $\psi_1\psi_1 \rightarrow \ell\bar{\ell}\gamma$ and $\psi_1\psi_1 \rightarrow \gamma\gamma$. The combination of the thermally averaged cross sections, $\langle\sigma v\rangle_{\mu\bar{\mu}\gamma} + 2\langle\sigma v\rangle_{\gamma\gamma}$, is constrained to be less than $10^{-26}\text{--}10^{-27}\text{ cm}^3/\text{s}$, depending on the DM mass. The cross sections of these annihilation processes, however, are several orders of magnitude smaller than that of $\langle\sigma v\rangle_{\mu\bar{\mu}}$ in our model, and therefore, ref. [105] does not put a constraint on the parameter region shown in Fig. 3. It is notable that due to the gauge invariance, we should consider the $\psi_1\psi_1 \rightarrow \ell\bar{\ell}\gamma$ process together with the $\psi_1\psi_1 \rightarrow \ell\bar{\ell}Z$ process. Such processes may be able to be explored by the PAMELA anti-proton search [106], and there are studies for Majorana DM models [107, 108], although they indicate that it is difficult to observe a Majorana DM at current and future telescopes.

3. Direct detection

Our Majorana DM scattering with the nucleon is induced by interactions presented in Eq. (3.7). For the current parameter set, we obtain the SI DM-nucleon scattering cross section of $\mathcal{O}(10^{-47}\text{--}10^{-50})\text{ cm}^2$. This is smaller than the current limit from the LZ experiment [62], which is $(1.5\text{--}2.4) \times 10^{-46}\text{ cm}^2$ for the DM mass range in Fig. 3. The LZ experiment [62] also put constraints on the SD DM-proton and DM-neutron scattering cross sections, but both are weaker than that of the SI cross section, and therefore, no region of the parameter space is excluded by direct detection experiments. With the future sensitivity of the LZ experiment, the upper limit on the SI cross section will be improved by one order of magnitude [109, 110], which is still not sufficient to explore our parameter space. By the future sensitivity of PandaX-4T with 5.6 tonne-year exposure [111], we may be able to explore the parameter space in Fig. 3. Their current limit on the SI DM-nucleon scattering cross section [65] can be read as $(2.6\text{--}4.2) \times 10^{-46}\text{ cm}^2$ for the DM mass range of $550\text{ GeV} \leq m_{\psi_1} \leq 860\text{ GeV}$, and hence, if the future limit is improved by a few orders of magnitude, a heavy DM mass region with $m_{\psi_1} \simeq m_{\varphi_1^+}$ will be explored at the PandaX-4T experiment.

Finally, let us discuss how our new physics contributions to Δa_μ and d_μ depend

on input parameter choices. First of all, a different choice of θ_{phys} can change our predictions for Δa_μ and d_μ shown in Fig. 3. It is expected that d_μ is maximized by choosing $\theta_{\text{phys}} \sim \pi/4$, because $\theta_{\text{phys}} \rightarrow 0$ or $\theta_{\text{phys}} \rightarrow \pi/2$ leads to $d_\mu \approx 0$. On the other hand, the contribution to Δa_μ does not have such a clear dependence on θ_{phys} . Actually, both observables strongly depend on the input parameter set of $(m_D, m_{LL}, m_{RR}, \theta_{\text{phys}})$. For example, if $(m_D, m_{LL}, m_{RR}) = (700 \text{ GeV}, 200 \text{ GeV}, 1000 \text{ GeV})$ are chosen, $\Delta a_\mu < 0$ for $0 < \theta_{\text{phys}} \lesssim 0.42$ and the 2σ deviation can be explained for $\pi/6 < \theta_{\text{phys}} < \pi/4$, and d_μ is maximized around $\theta_{\text{phys}} \simeq \pi/6$. Instead, if we choose $(m_D, m_{LL}, m_{RR}) = (500 \text{ GeV}, 990 \text{ GeV}, 1000 \text{ GeV})$, $\Delta a_\mu < 0$ is predicted in almost all range of θ_{phys} and the 2σ deviation can be explained only around $\theta_{\text{phys}} \simeq 1.45$, and the peak of d_μ appears at $\theta_{\text{phys}} \simeq 1.35$. In any case, our prediction of the muon EDM is $d_\mu > \mathcal{O}(10^{-22}) e \text{ cm}$. These observables also depend on the values of M_ϕ^2, M_η^2 . As one can see in Fig. 3, the predictions of Δa_μ and d_μ become small as $m_{\varphi_1^+}$ increases. In contrast, a large a enhances the contributions by a few %. This is because a is related to the difference between $m_{\varphi_1^+}^2$ and $m_{\varphi_2^+}^2$ (see Eqs. (2.19) and (2.20)), and hence, a larger a leads to a slightly smaller $m_{\varphi_1^+}^2$.

5 Conclusion

In the present paper, we have investigated a prediction for the muon EDM obtained in a model of DM. As shown in Table 1, the radiative stability approach has a clear advantage to enhance the muon EDM, and we focused on a model in which the muon mass is generated radiatively. With appropriate discrete symmetries, exotic particles, ψ , ϕ and η , have couplings to the muon (and also to the SM Higgs doublet). In this model, one of the complex phases in the couplings cannot be removed by any field redefinition and provides a physical CP phase, which leads to a new contribution to the muon EDM. $\psi_{L,R}$ are singlet under the SM gauge groups and the lightest mode gives a candidate of the Majorana fermion DM.

We found that even when the DM mass is heavier than the current collider bound, $m_{\psi_1} > 500 \text{ GeV}$, the model predicts a muon EDM larger than $10^{-22} e \text{ cm}$ which can be tested at the PSI muEDM experiment. In the parameter space where the discrepancy of the muon $g - 2$ and the correct DM relic density are explained at the same time, the model predicts $d_\mu \simeq (4\text{-}5) \times 10^{-22} e \text{ cm}$. For the case of $m_{\psi_1} > m_{\varphi_1^+}$, the muon EDM can be even larger, $d_\mu \simeq (7\text{-}8) \times 10^{-22} e \text{ cm}$, due to a small value of $m_{\varphi_1^+}$, although ψ_1 does not give a DM candidate. Furthermore, once we forget a new physics explanation for the muon $g - 2$ discrepancy as well as the DM relic density, the muon EDM can be

larger than the future sensitivities of the ongoing Fermilab Muon $g - 2$ and projected J-PARC Muon $g - 2$ /EDM experiments.

One of the most promising approaches to probe our DM model is a future muon collider (see e.g. ref. [112] and references therein) because a muon collider is expected to have a new particle mass reach higher than that of the LHC and also our DM fermion directly couples to the muon. It would be interesting to explore the phenomenology of our DM model to generate the radiative muon mass, the muon $g - 2$ and the muon EDM at a muon collider, which is left for future study.

A Neutrino sector

A.1 A scalar triplet extension

In our model, due to the muon number symmetry, we need a further extension for obtaining the correct neutrino mixing angles. One of the simplest way to reproduce them is to introduce a scalar triplet, as discussed in appendix A of ref. [113]. At first, we can write down dimension-five operators which are related to lepton doublets as

$$-\frac{c_{HH}^{ab}}{M_{HH}} \left(\overline{L}_L^a \tilde{H} \right) \left(\tilde{H}^T (L_L^c)^b \right) + \text{h.c.}, \quad (\text{A.1})$$

where $\tilde{H} = i\sigma_2 H^*$, and $a, b = e, \mu, \tau$ are indices for lepton species. Note that the exotic number symmetry forbids terms of $\left(\overline{L}_L^a \tilde{H} \right) \left(\tilde{\phi}^T (L_L^c)^b \right)$ and $\left(\overline{L}_L^a \tilde{\phi} \right) \left(\tilde{H}^T (L_L^c)^b \right)$, and the term of $\left(\overline{L}_L^a \tilde{\phi} \right) \left(\tilde{\phi}^T (L_L^c)^b \right)$ is irrelevant to the discussion on the neutrino mixing angles, because ϕ does not acquire a nonzero VEV. The coefficient c_{HH} is a 3×3 matrix, but symmetries of the model makes it have the form,

$$c_{HH} = \begin{pmatrix} c_{HH}^{ee} & 0 & c_{HH}^{e\tau} \\ 0 & c_{HH}^{\mu\mu} & 0 \\ c_{HH}^{\tau e} & 0 & c_{HH}^{\tau\tau} \end{pmatrix}. \quad (\text{A.2})$$

Therefore, the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) matrix obtained from our model cannot be consistent with the experimental result at this stage. However, once

we introduce a $SU(2)_L$ triplet scalar Δ to the model, which has the $U(1)_Y$ charge of -1 and odd muon number, we can write additional terms of

$$-c_{\Delta}^{ab}\overline{L}_L^a\Delta(L_L^c)^b, \quad c_{\Delta} = \begin{pmatrix} 0 & c_{\Delta}^{e\mu} & 0 \\ c_{\Delta}^{\mu e} & 0 & c_{\Delta}^{\mu\tau} \\ 0 & c_{\Delta}^{\tau\mu} & 0 \end{pmatrix}. \quad (\text{A.3})$$

When Δ acquires a nonzero VEV, $v_{\Delta} \neq 0$, we can reproduce all elements for the neutrino mass matrix as

$$m_{\nu} = \begin{pmatrix} (m_{\nu})^{ee} & (m_{\nu})^{e\mu} & (m_{\nu})^{e\tau} \\ (m_{\nu})^{\mu e} & (m_{\nu})^{\mu\mu} & (m_{\nu})^{\mu\tau} \\ (m_{\nu})^{\tau e} & (m_{\nu})^{\tau\mu} & (m_{\nu})^{\tau\tau} \end{pmatrix}. \quad (\text{A.4})$$

Here, each $(m_{\nu})^{ab}$ is estimated by

$$(m_{\nu})^{ab} = \begin{cases} \frac{c_{HH}^{ab}}{2} \frac{v_H^2}{M_{HH}} & \text{for } (a, b) = (e, e), (e, \tau), (\mu, \mu), (\tau, e), (\tau, \tau) \\ c_{\Delta}^{ab} v_{\Delta} & \text{for } (a, b) = (e, \mu), (\mu, e), (\mu, \tau), (\tau, \mu) \end{cases}. \quad (\text{A.5})$$

Then, if v_{Δ} is $\mathcal{O}(v_H^2/M_{HH})$ with $c_{HH}^{ab} \sim c_{\Delta}^{ab}$, all elements of Eq. (A.4) have the similar order, and hence, the large mixing angles for the PMNS matrix can be obtained. For the neutrino masses of $\mathcal{O}(\text{eV})$, the mass scale for M_{HH} is required to be $\mathcal{O}(10^{13-14})$ GeV.

A.2 Right-handed neutrinos

Another possibility to reproduce the correct PMNS matrix is to introduce three generations of the right-handed neutrinos (RHNs), denoted as $N_R^{e,\mu,\tau}$. Similar to the charged lepton sector, only N_R^{μ} is odd under the muon number L_{μ} , and we have additional Dirac Yukawa couplings and Majorana mass terms for neutrinos as ($\ell^{(\prime)} = e, \tau$)

$$\mathcal{L}_N = -y_{\nu}^{\ell\ell'}\overline{L}_L^{\ell}\widetilde{H}N_R^{\ell'} - y_{\nu}^{\mu\mu}\overline{L}_L^{\mu}\widetilde{H}N_R^{\mu} - m_N^{\ell\ell'}\overline{N}_R^{\ell c}N_R^{\ell'} - m_N^{\mu\mu}\overline{N}_R^{\mu c}N_R^{\mu} - m_N^{\ell\mu}\overline{N}_R^{\ell c}N_R^{\mu} + \text{h.c.}, \quad (\text{A.6})$$

where the last term breaks the L_{μ} symmetry softly, which is required for the correct neutrino mixing angles. This can be understood diagrammatically, as shown in Fig. 4. In addition to this diagram, the mixing between ν_L^e and ν_L^{τ} is also induced by the same

Figure 4: A Feynman diagram for the neutrino mixing between ν_L^μ and $\nu_L^{e,\tau}$ where “ \times ” indicates the soft breaking mixing between N_R^μ and $N_R^{e,\tau}$.

Figure 5: One-loop contributions to off-diagonal elements of Yukawa couplings of charged leptons. Here, ν_R^α is the mass eigenstate of RHNs.

diagram with changing $\mu \rightarrow e$ or τ . The mass matrix of $\nu_L^{e,\mu,\tau}$ can be obtained as

$$m_{\nu_L} = -\frac{v_H^2}{2} \begin{pmatrix} y_\nu^{ee} & 0 & y_\nu^{e\tau} \\ 0 & y_\nu^{\mu\mu} & 0 \\ y_\nu^{\tau e} & 0 & y_\nu^{\tau\tau} \end{pmatrix} \begin{pmatrix} m_N^{ee} & m_N^{e\mu} & m_N^{e\tau} \\ m_N^{\mu e} & m_N^{\mu\mu} & m_N^{\mu\tau} \\ m_N^{\tau e} & m_N^{\tau\mu} & m_N^{\tau\tau} \end{pmatrix}^{-1} \begin{pmatrix} y_\nu^{ee} & 0 & y_\nu^{e\tau} \\ 0 & y_\nu^{\mu\mu} & 0 \\ y_\nu^{e\tau} & 0 & y_\nu^{\tau\tau} \end{pmatrix}. \quad (\text{A.7})$$

Therefore, if the mass scales of $m_N^{\ell\ell'}$ are similar with each other, we can obtain a full 3×3 matrix for light neutrino states, which can be consistent with experimental results on the PMNS matrix. Similar to the previous method, the mass scale of $m_N^{\ell\ell'}$ is required to be $\mathcal{O}(10^{13-14})$ GeV for the neutrino masses of $\mathcal{O}(\text{eV})$ if $y_\nu^{\ell\ell'} \sim \mathcal{O}(1)$.

A.3 Comment on LFV

For the second example, however, we have LFV processes due to the soft L_μ breaking terms. To see this, we focus on the first two generations of leptons, namely, the electron-muon system. From Eq. (A.6) and the SM Yukawa interactions for the electron, we have one-loop contributions to off-diagonal elements of Yukawa couplings of charged leptons, as shown in Fig. 5. Due to the soft L_μ breaking, the mass eigenstate ν_R^α can be written

by one mixing angle θ_N as

$$\begin{pmatrix} \nu_R^1 \\ \nu_R^2 \end{pmatrix} = \begin{pmatrix} \cos \theta_N & \sin \theta_N \\ -\sin \theta_N & \cos \theta_N \end{pmatrix} \begin{pmatrix} N_R^e \\ N_R^\mu \end{pmatrix}. \quad (\text{A.8})$$

After integrating out the RHNs, we obtain the off-diagonal element,

$$\mathcal{L}_{\text{eff}} \supset -\delta y_{\mu e} \overline{L}_L^\mu H e_R + \text{h.c.}, \quad (\text{A.9})$$

where $\delta y_{\mu e}$ is obtained by Fig. 5 and roughly estimated as

$$\delta y_{\mu e} \simeq \frac{y_e}{16\pi^2} y_\nu^{ee} y_\nu^{\mu\mu} \sin \theta_N \cos \theta_N \ln \frac{M_{\nu_R^1}^2}{M_{\nu_R^2}^2}, \quad (\text{A.10})$$

with y_e being the SM Yukawa coupling of the term $\overline{L}_L^e H e_R$. This off-diagonal element can be removed by field redefinition of left-handed lepton doublets,

$$\ell_L^e = L_L^e \cos \theta_{e\mu} + L_L^\mu \sin \theta_{e\mu}, \quad \ell_L^\mu = -L_L^e \sin \theta_{e\mu} + L_L^\mu \cos \theta_{e\mu}, \quad (\text{A.11})$$

which lead to an electron coupling with exotic particles,

$$y_\phi \overline{L}_L^\mu \phi^\dagger \psi_R \rightarrow y_\phi^e \overline{\ell}_L^e \phi^\dagger \psi_R + y_\phi^\mu \overline{\ell}_L^\mu \phi^\dagger \psi_R, \quad (\text{A.12})$$

where we define $y_\phi^e \equiv y_\phi \sin \theta_{e\mu}$ and $y_\phi^\mu \equiv y_\phi \cos \theta_{e\mu}$. Then, we have a one-loop contribution to $\mu \rightarrow e\gamma$ by replacing $\mu_L \rightarrow e_L$ in the diagram (b) of Fig. 1. Its branching ratio can be calculated as [114]

$$\text{BR}(\mu \rightarrow e\gamma) = \frac{3(4\pi)^3 \alpha}{2G_F^2 m_\mu^2} \left(|C_T^{e\mu}|^2 + |C_{T'}^{e\mu}|^2 \right) \text{BR}(\mu \rightarrow e\nu_\mu \bar{\nu}_e), \quad (\text{A.13})$$

where G_F is the Fermi constant, $\text{BR}(\mu \rightarrow e\nu_\mu \bar{\nu}_e) \approx 1$, and $C_T^{e\mu}$ and $C_{T'}^{e\mu}$ are coefficients of dipole operators, whose definitions are

$$\mathcal{L}_{\text{LFV}} \supset -\frac{e}{2} C_T^{e\mu} (\bar{e} \sigma^{\alpha\beta} \mu) F_{\alpha\beta} - \frac{e}{2} C_{T'}^{e\mu} (\bar{e} i \sigma^{\alpha\beta} \gamma_5 \mu) F_{\alpha\beta}. \quad (\text{A.14})$$

From Eqs. (2.28), (2.33) and (2.34), leading contributions to $C_T^{e\mu}$ and $C_{T'}^{e\mu}$ can be easily estimated by replacing $y_L^{ia} \rightarrow y_L^{ia} \sin \theta_{e\mu}$. Similar to this replacement, our predictions of a_μ and d_μ in Eqs. (2.31) and (2.32) are changed as

$$a_\mu = 2m_\mu (C_T(0) \cos \theta_\mu + C_{T'}(0) \sin \theta_\mu) \cos \theta_{e\mu}, \quad (\text{A.15})$$

$$d_\mu = e (C_{T'}(0) \cos \theta_\mu - C_T(0) \sin \theta_\mu) \cos \theta_{e\mu}. \quad (\text{A.16})$$

From these facts, we have the following relation between $C_T^{e\mu}$, $C_{T'}^{e\mu}$ and a_μ , d_μ as

$$\begin{aligned} |C_T^{e\mu}|^2 + |C_{T'}^{e\mu}|^2 &= \left(|C_T(0)c_{\theta_\mu/2} + C_{T'}(0)s_{\theta_\mu/2}|^2 + |C_{T'}(0)c_{\theta_\mu/2} - C_T(0)s_{\theta_\mu/2}|^2 \right) \sin^2 \theta_{e\mu} \\ &= (|C_T(0)|^2 + |C_{T'}(0)|^2) \sin^2 \theta_{e\mu} \\ &= \left(\left| \frac{a_\mu}{2m_\mu} \right|^2 + \left| \frac{d_\mu}{e} \right|^2 \right) \tan^2 \theta_{e\mu}, \end{aligned} \quad (\text{A.17})$$

and hence, the branching ratio in Eq. (A.13) can be expressed by a_μ and d_μ as

$$\text{BR}(\mu \rightarrow e\gamma) = \frac{3(4\pi)^3 \alpha}{2G_F^2 m_\mu^2} \left(\left| \frac{a_\mu}{2m_\mu} \right|^2 + \left| \frac{d_\mu}{e} \right|^2 \right) \tan^2 \theta_{e\mu}. \quad (\text{A.18})$$

By assuming $a_\mu = 2.51 \times 10^{-9}$ and $d_\mu = 4.5 \times 10^{-22} e \text{ cm}$ as we found in our model, the upper limit on $\tan \theta_{e\mu}$ can be obtained as

$$\tan \theta_{e\mu} \lesssim 6.7 \times 10^{-6}, \quad (\text{A.19})$$

where we have used the current upper bound on the branching ratio, $\text{BR}(\mu \rightarrow e\gamma) < 4.2 \times 10^{-13}$ [115]. Then, the mixing angle in Eq. (A.11) should be tiny, which means a small off-diagonal element compared to y_e , $\delta y_{\mu e} \ll y_e$. To realize the constraint in Eq. (A.19), we roughly need $\delta y_{\mu e}/y_e \sim 6 \times 10^{-6}$. Assuming $\ln(M_{\nu_R^1}^2/M_{\nu_R^2}^2) \sim \mathcal{O}(1)$ and $\sin \theta_N \sim \cos \theta_N \sim 1/\sqrt{2}$ due to the similar order for all $m_N^{\ell\ell'}$ to obtain large mixing angles for neutrinos, we obtain $y_\nu^{ee} y_\nu^{\mu\mu} \sim 2 \times 10^{-3}$, and the scale of RHNs will be $\mathcal{O}(10^{10})$ GeV for the light neutrino masses of $\mathcal{O}(\text{eV})$.

B Loop integrals

In the appendix, we summarize loop integrals relevant to our analysis. Note that we use dimensional regularization, and $\Delta_\epsilon \equiv \frac{2}{\epsilon} - \gamma_E + \ln 4\pi$ with the Euler constant γ_E and $\epsilon = 4 - D$ diverges when $D \rightarrow 4$.

– Self-energy integral –

$$B_0(p^2, m_0^2, m_1^2) = \Delta_\epsilon - \int_0^1 dx \ln \left[\frac{-x(1-x)p^2 + xm_1^2 + (1-x)m_0^2}{\mu^2} \right]. \quad (\text{B.1})$$

When $p^2 = 0$ and $m_0^2 = m_1^2 \equiv m^2$, we can obtain the following simple form:

$$B_0(0, m^2, m^2) = \Delta_\epsilon - \ln \frac{m^2}{\mu^2}. \quad (\text{B.2})$$

Note that B_0 has a divergent part which should be cancelled for physical predictions.

– Triangle integrals –

$$C_0(p_1^2, p_{12}^2, p_2^2, m_0^2, m_1^2, m_2^2) = - \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \frac{1}{C_3}, \quad (\text{B.3})$$

$$C_1(p_1^2, p_{12}^2, p_2^2, m_0^2, m_1^2, m_2^2) = \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \frac{x_1}{C_3}, \quad (\text{B.4})$$

$$C_{ij}(p_1^2, p_{12}^2, p_2^2, m_0^2, m_1^2, m_2^2) = - \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \frac{x_i x_j}{C_3}, \quad (\text{B.5})$$

where $C_3 = x_1(x_1 - 1)p_1^2 + x_2(x_2 - 1)p_2^2 + x_1x_2(p_1^2 + p_2^2 - p_{12}^2) + x_1m_1^2 + x_2m_2^2 + (1 - x_1 - x_2)m_0^2$ with $p_{12}^2 = (p_1 - p_2)^2$. When all of p_1^2 , p_2^2 and p_{12}^2 are 0, these integrals are simplified as follows. First, the C_0 function is (here we use $r_i \equiv m_i^2/m_0^2$):

$$C_0(0, 0, 0, m_0^2, m_1^2, m_2^2) = \frac{1}{m_0^2} \frac{r_1 \ln r_1 - r_1 r_2 \ln r_1 - r_2 \ln r_2 + r_1 r_2 \ln r_2}{(1 - r_1)(1 - r_2)(r_1 - r_2)}, \quad (\text{B.6})$$

$$C_0(0, 0, 0, m_0^2, m_1^2, m_1^2) = \frac{1}{m_0^2} \frac{1 - r_1 + \ln r_1}{(1 - r_1)^2}, \quad (\text{B.7})$$

$$C_0(0, 0, 0, m_0^2, m_0^2, m_0^2) = -\frac{1}{2m_0^2}. \quad (\text{B.8})$$

Note that $C_0(0, 0, 0, m_0^2, m_1^2, m_2^2)$ is symmetric under exchanging two of m_i^2 , e.g., $C_0(0, 0, 0, m_0^2, m_1^2, m_2^2) = C_0(0, 0, 0, m_0^2, m_2^2, m_1^2) = C_0(0, 0, 0, m_0^2, m_2^2, m_1^2)$.

Second, the C_1 function is simplified as

$$C_1(0, 0, 0, m_0^2, m_1^2, m_2^2) = -\frac{1}{2m_0^2} \left[\frac{r_1}{(1 - r_1)(r_1 - r_2)} + \frac{r_1(r_1 - 2r_2 + r_1 r_2)}{(1 - r_1)^2(r_1 - r_2)^2} \ln r_1 \right. \\ \left. + \frac{r_2^2}{(1 - r_2)(r_1 - r_2)^2} \ln r_2 \right], \quad (\text{B.9})$$

$$C_1(0, 0, 0, m_0^2, m_1^2, m_1^2) = -\frac{1}{4m_0^2} \frac{r_1^2 - 4r_1 + 3 + 2 \ln r_1}{(1 - r_1)^3}, \quad (\text{B.10})$$

$$C_1(0, 0, 0, m_0^2, m_0^2, m_0^2) = \frac{1}{6m_0^2}. \quad (\text{B.11})$$

Note that there is a symmetric property only for $m_0^2 \leftrightarrow m_2^2$, $C_1(0, 0, 0, m_0^2, m_1^2, m_2^2) = C_1(0, 0, 0, m_2^2, m_1^2, m_0^2)$.

Third, the C_{11} function is

$$C_{11}(0, 0, 0, m_0^2, m_1^2, m_2^2) = -\frac{1}{3m_0^2} \left[\frac{r_1(r_1^2 - 3r_1 + 5r_2 - 3r_1 r_2)}{2(1 - r_1)^2(r_1 - r_2)^2} \right. \\ \left. - \frac{r_1(r_1^2 r_2^2 + r_1^2 r_2 + r_1^2 - 3r_1 r_2^2 - 3r_1 r_2 + 3r_2^2)}{(1 - r_1)^3(r_1 - r_2)^3} \ln r_1 \right]$$

$$+\frac{r_2^3}{(1-r_2)(r_1-r_2)^3}\ln r_2\Big], \quad (\text{B.12})$$

$$C_{11}(0,0,0,m_0^2,m_1^2,m_1^2)=-\frac{1}{18m_0^2}\frac{2r_1^3-9r_1^2+18r_1-11-6\ln r_1}{(1-r_1)^4}, \quad (\text{B.13})$$

$$C_{11}(0,0,0,m_0^2,m_0^2,m_0^2)=-\frac{1}{12m_0^2}. \quad (\text{B.14})$$

Finally, the C_{12} function is

$$C_{12}(0,0,0,m_0^2,m_1^2,m_2^2)=-\frac{1}{6m_0^2}\left[\frac{r_1^2r_2-r_1^2+r_1r_2^2-r_2^2}{(1-r_1)(1-r_2)(r_1-r_2)^2}-\frac{r_1^2(2r_1r_2+r_1-3r_2)}{(1-r_1)^2(r_1-r_2)^3}\ln r_1+\frac{r_2^2(2r_1r_2-3r_1+r_2)}{(1-r_2)^2(r_1-r_2)^3}\ln r_2\right], \quad (\text{B.15})$$

$$C_{12}(0,0,0,m_0^2,m_1^2,m_1^2)=-\frac{1}{36m_0^2}\frac{2r_1^3-9r_1^2+18r_1-11-6\ln r_1}{(1-r_1)^4}, \quad (\text{B.16})$$

$$C_{12}(0,0,0,m_0^2,m_0^2,m_0^2)=-\frac{1}{24m_0^2}. \quad (\text{B.17})$$

C Full forms for y_μ^{eff} , C_T and $C_{T'}$

We here present full expressions for y_μ^{eff} , C_T and $C_{T'}$ at the one-loop order. In their calculations, `FeynCalc` [116–118] is used, and to deal with γ_5 in dimensional regularization, we adopt the 't Hooft-Veltman-Breitenlohner-Maison (BMHV) prescription [119, 120]. The results are

$$y_\mu^{\text{eff}}(p_{h^0}^2)=\sum_{i,j,a}\left\{-\frac{y_L^{ia}y_R^{ja}A_{ij}}{16\pi^2}m_{\psi_a}C_0(m_\mu^2,m_\mu^2,p_{h^0}^2,m_{\varphi_i^+}^2,m_{\psi_a}^2,m_{\varphi_j^+}^2)+\frac{A_{ij}}{16\pi^2}m_\mu^{\text{rad}}\left[y_R^{ia*}y_R^{ja}C_1(m_\mu^2,p_{h^0}^2,m_\mu^2,m_{\psi_a}^2,m_{\varphi_i^+}^2,m_{\varphi_j^+}^2)+y_L^{ia}y_L^{ja*}C_2(m_\mu^2,p_{h^0}^2,m_\mu^2,m_{\psi_a}^2,m_{\varphi_i^+}^2,m_{\varphi_j^+}^2)\right]\right\}, \quad (\text{C.1})$$

$$C_T(q^2)=\sum_{i,a}\left\{\frac{\text{Re}[y_L^{ia}y_R^{ia}]}{16\pi^2}m_{\psi_a}\left[Q_S\left(C_0(q^2,m_{\psi_a}^2,m_{\varphi_i^+}^2)+2C_1(q^2,m_{\psi_a}^2,m_{\varphi_i^+}^2)\right)-2Y_\psi C_1(q^2,m_{\varphi_i^+}^2,m_{\psi_a}^2)\right]-\frac{|y_L^{ia}|^2+|y_R^{ia}|^2}{16\pi^2}\text{Re}[m_\mu^{\text{rad}}]\left[Q_S C_{\text{sub}}(q^2,m_{\psi_a}^2,m_{\varphi_i^+}^2)\right]\right\}$$

$$+ Y_\psi C_{\text{sub}}(q^2, m_{\varphi_i^+}^2, m_{\psi_a}^2) \Big] \Big\}, \quad (\text{C.2})$$

$$C_{T'}(q^2) = \sum_{i,a} \left\{ \frac{\text{Im}[y_L^{ia} y_R^{ia}]}{16\pi^2} m_{\psi_a} \left[Q_S \left(C_0(q^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) + 2C_1(q^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) \right) \right. \right. \\ \left. \left. - 2Y_\psi C_1(q^2, m_{\varphi_i^+}^2, m_{\psi_a}^2) \right] \right. \\ \left. - \frac{|y_L^{ia}|^2 + |y_R^{ia}|^2}{16\pi^2} \text{Im}[m_\mu^{\text{rad}}] \left[Q_S C_{\text{sub}}(q^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) \right. \right. \\ \left. \left. + Y_\psi C_{\text{sub}}(q^2, m_{\varphi_i^+}^2, m_{\psi_a}^2) \right] \right\}, \quad (\text{C.3})$$

where $Q_S = 1 + Y_\psi$, and we have defined

$$C_0(q^2, m_{\psi_a}^2, m_{\varphi_i^+}^2) \equiv C_0(m_\mu^2, m_\mu^2, q^2, m_{\varphi_i^+}^2, m_{\psi_a}^2, m_{\varphi_i^+}^2), \quad (\text{C.4})$$

$$C_N(q^2, m_A^2, m_B^2) \equiv C_N(m_\mu^2, q^2, m_\mu^2, m_A^2, m_B^2, m_B^2) \quad (N = 1, 11, 12), \quad (\text{C.5})$$

and for sub-leading contributions, we have also defined

$$C_{\text{sub}}(q^2, m_A^2, m_B^2) \equiv C_1(q^2, m_A^2, m_B^2) + C_{11}(q^2, m_A^2, m_B^2) + C_{12}(q^2, m_A^2, m_B^2). \quad (\text{C.6})$$
