# AUTOMORPHISMS AND TWISTED FORMS OF RINGS OF INVARIANTS 

JÁNOS KOLLÁR

#### Abstract

Let $G \subset \operatorname{GL}_{n}(k)$ be a finite subgroup and $k\left[x_{1}, \ldots, x_{n}\right]^{G} \subset$ $k\left[x_{1}, \ldots, x_{n}\right]$ its ring of invariants. We show that, in many cases, the automorphism group of $k\left[x_{1}, \ldots, x_{n}\right]^{G}$ is $k^{\times}$.

Let $k$ be a field and $G \subset \mathrm{GL}_{n}(k)$ a finite subgroup. Then $G$ also acts on the polynomial ring $k\left[x_{1}, \ldots, x_{n}\right]$ and on the power series ring $k\left[\left[x_{1}, \ldots, x_{n}\right]\right]$, which we abbreviate as $k[\mathbf{x}]$ (resp. $k[[\mathbf{x}]]$ ). The ring of invariants is denoted by $k[\mathbf{x}]^{G}$ (resp. $\left.k[[\mathbf{x}]]^{G}\right)$. Our aim is to describe the automorphism groups of these rings.

Let $N(G):=N\left(G, \mathrm{GL}_{n}(k)\right)$ denote the normalizer of $G$ in $\mathrm{GL}_{n}(k)$. Then the $N(G)$-action on $k[\mathbf{x}]$ descends to an $N(G) / G$-action on $k[\mathbf{x}]^{G}$. We prove that these automorphisms of $k[\mathbf{x}]^{G}$ and $k[[\mathbf{x}]]^{G}$ give the largest reductive quotient/subgroup of the automorphism group.

The normalizer always contains the scalars $k^{\times}$. They act on homogeneous polynomials as $p(\mathbf{x}) \mapsto \lambda^{\operatorname{deg} p} p(\mathbf{x})$, but we get a sometimes larger $k^{\times}$-action given as $p(\mathbf{x}) \mapsto \lambda^{(\operatorname{deg} p) / e} p(\mathbf{x})$, where $e$ is the gcd of the degrees of all homogeneous $G$ invariants.

Other automorphisms are not always easy to write down, and it turns out that, depending on $G, \operatorname{Aut}\left(k[\mathbf{x}]^{G}\right)$ is sometimes infinite dimensional, and sometimes 1 dimensional. We give criteria for both extremes, but a complete answer remains conjectural.

More generally, we consider rings of invariants by finite, geometrically reduced subgroup schemes $G \subset \mathrm{GL}_{n}$ over $k$.

If char $k$ does not divide $|G|$, then, by the Chevalley-Shephard-Todd theorem Che55, $k[\mathbf{x}]^{G} \cong k[\mathbf{y}]^{H}$ for a suitable $H$-action, where $H$ is the quotient of $G$ by the subgroup generated by all pseudo-reflections, that is, elements that fix a hyperplane pointwise. Thus we can harmlessly assume that $G$ does not contain any pseudo-reflections. The situation is less clear if char $k$ divides $|G|$.

Our first result computes $\operatorname{Aut}\left(k[\mathbf{x}]^{G}\right)$ in terms of $G \subset \operatorname{Aut}(k[\mathbf{x}])$.
Theorem 1. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced subgroup scheme without pseudo-reflections. Assume that
(1) either $R=k[[\mathbf{x}]]$,
(2) or $R=k[\mathbf{x}]$, char $k \nmid|G|$, and $0 \in k^{n}$ is the only $G$-invariant vector.

Then there is a split exact sequence

$$
\begin{equation*}
1 \rightarrow C\left(G, \operatorname{Aut}^{\mathrm{u}}(R)\right) \rightarrow \operatorname{Aut}\left(R^{G}\right) \rightarrow\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k) \rightarrow 1 \tag{11.3}
\end{equation*}
$$

Here $\operatorname{Aut}^{\mathrm{u}}(R) \subset \operatorname{Aut}(R)$ denotes the subgroup of those automorphisms that stabilize the maximal ideal $m=\left(x_{1}, \ldots, x_{n}\right)$ and act trivially on $m / m^{2}$. It is the
group of $k$-points of an infinite dimensional ind-group Sha66, Sha81, FK18, but the ind-group structure plays no role for us.
$C(G, *)$ denotes the centralizer, the subgroup of those elements of $*$ that commute with $G$. If the origin is the only $G$-fixed point, then the maximal ideal $m$ is also fixed by the normalizer $N(G, \operatorname{Aut}(R))$, so $N(G, \operatorname{Aut}(R))=N(G, \operatorname{Aut}(R, m))$. Since $\operatorname{Aut}^{\mathrm{u}}(R)$ is a normal subgroup of $\operatorname{Aut}(R, m)$, and its intersection with $\mathrm{GL}_{n}$ is the identity, the normalizer $N\left(G, \mathrm{Aut}^{\mathrm{u}}(R)\right)$ equals the centralizer $C\left(G, \mathrm{Aut}^{\mathrm{u}}(R)\right)$.

On the right in (113), $\mathbf{N}\left(G, \mathrm{GL}_{n}\right)$ denotes the normalizer of $G$ in $\mathrm{GL}_{n}$, as an algebraic group over $k$. We take the quotient by $G$, as an algebraic group, and then the $k$-points of the quotient. It is usually larger than $N\left(G, \mathrm{GL}_{n}(k)\right) / G(k)$, but the two agree if either $k$ is separably closed, or if $G$ acts irreducibly, and its center is trivial; see Examples 6. 8 In any case, this part is quite well understood.

On the left in (1] 3$) C\left(G, \operatorname{Aut}^{\mathrm{u}}(k[[\mathbf{x}]])\right)$ is always infinite dimensional, see Example 11, By contrast, $C\left(G, \operatorname{Aut}^{\mathrm{u}}(k[\mathbf{x}])\right)$ is sometimes trivial. It is infinite dimensional, whenever $G$ is diagonalizable over $k$, see Example 9 The same holds for most reducible representations by Example 10. However, for irreducible representations, the following could be true.

Conjecture 2. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced subgroup scheme that acts irreducibly over $k$. Then $C\left(G, \operatorname{Aut}^{\mathrm{u}}(k[\mathbf{x}])\right)=\{1\}$.

We show this in dimension 2 for any $k$ in Theorem 42, and in dimension 3 for $k=\mathbb{C}$ in Proposition 43, In higher dimensions, we develop a notion of birationally irreducible representations (see Definition 31) and give a series of examples in (3540). (Very roughly speaking, $G$ is birationally irreducible if the induced action on $\mathbb{P}_{k}^{n-1}$ is not birational to an action on a product.) We prove the following special case of Conjecture 2,

Theorem 3. Let $G \subset \mathrm{GL}_{n}$ be a geometrically reduced and birationally irreducible subgroup scheme. Then the centralizer $C\left(G, \operatorname{Aut}^{\mathrm{u}}(k[\mathbf{x}])\right)$ is trivial.

Combining the two theorems gives the following.
Corollary 4. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, birationally irreducible subgroup scheme without pseudo-reflections. Assume that char $k \nmid|G|$. Then

$$
\operatorname{Aut}\left(k[\mathbf{x}]^{G}\right)=\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k)
$$

The sequence (1.3) also allows us to determine the twisted forms of quotient singularities, where a twisted form of a $k$-algebra $A$ is a $k$-algebra $A^{\prime}$, such that $\bar{k} \otimes_{k} A \cong \bar{k} \otimes_{k} A^{\prime}$. For illustrations see Examples 5152 .

Corollary 5. Let $k$ be a perfect field with algebraic closure $\bar{k} \supset k$ and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced $k$-subgroup scheme without pseudo-reflections. Let $N\left(G, \mathrm{GL}_{n}(\bar{k})\right) \subset \mathrm{GL}_{n}(\bar{k})$ be the normalizer of $G$. Then there are natural bijections between the sets
(1) twisted forms of $k[[\mathbf{x}]]^{G}$ (up to isomorphisms),
(2) grading preserving twisted forms of $k[\mathbf{x}]^{G}$ (up to isomorphisms), and
(3) $H^{1}\left(\operatorname{Gal}(\bar{k} / k), N\left(G, \operatorname{GL}_{n}(\bar{k})\right) / G(\bar{k})\right)$.

The proof of Theorem 1 builds on AZ13]. A key case is computed in AU22. The proof of Theorem 3 relies on the method of Jel94, as refined by Tot07. See BPVS23 for some related examples. Corollary 5 was inspired by BV22.

Acknowledgments. I thank G. Bresciani, Y. Tschinkel, U. Umirbaev, A. Vistoli and C. Xu for useful comments, and P. Tiep for giving the examples in (344). Partial financial support was provided by the NSF under grant number DMS-1901855.

## 1. Examples

We give a series of examples illustrating various possibilities for $\operatorname{Aut}\left(k[\mathbf{x}]^{G}\right)$.
Example 6. The automorphism groups of the $A_{n-1}$ singularities are quite interesting. Over a field $k$, write it as $\left(x^{2}-d y^{2}=z^{n}\right) \subset \mathbb{A}_{k}^{3}$ and assume that char $k \nmid 2 n$.

If $d$ is a square, it is equivalent to $\left(x y=z^{n}\right)$. This is the invariant ring of the $\mu_{n}$-action given by $(u, v) \mapsto\left(\epsilon u, \epsilon^{-1} v\right)$, where $\mu_{n} \subset \mathbb{G}_{m}$ is the group of $n$th roots of unity. For any polynomial $p(x)$ we get an automorphism

$$
\begin{equation*}
(x, y, z) \mapsto\left(x, y+\frac{(z+x p(x))^{n}-z^{n}}{x}, z+x p(x)\right) \tag{6,1}
\end{equation*}
$$

hence $\operatorname{Aut}\left(x y=z^{n}\right)$ is infinite dimensional.
If $d$ is not a square, then $\left(x^{2}-d y^{2}=z^{n}\right)$ is the invariant ring $k[u, v]^{G}$, where $G$ is the $n$-torsion subgroup of $\mathrm{SO}\left(u^{2}-d v^{2}\right)$. This is not diagonalizable over $k$. The connected component of its normalizer is

$$
\mathrm{GO}\left(u^{2}-d v^{2}\right)=\left\{\left(\begin{array}{cc}
c & s  \tag{16}\\
d s & c
\end{array}\right): c^{2}-d s^{2} \neq 0\right\} \subset \mathrm{GL}_{2}
$$

Adding the reflection $(u, v) \mapsto(-u, v)$ gives the whole normalizer.
Using Corollary 4 and Theorem 42, we need to compute $\mathrm{GO}\left(u^{2}-d v^{2}\right) / G$. We have 2 cases.

Case 6. 3. If $n=2 r+1$, then the reflection descends to $(x, y) \mapsto(-x, y)$, and

$$
\operatorname{Aut}^{\circ}\left(x^{2}-d y^{2}=z^{n}\right) \cong \mathrm{GO}\left(u^{2}-d v^{2}\right) / G \cong \mathrm{GO}\left(x^{2}-d y^{2}\right)
$$

where the quotient map is given by $N \mapsto \operatorname{det}^{-r} N \cdot N^{2 r+1}$, with $M \in \mathrm{GO}\left(x^{2}-d y^{2}\right)$ acting as

$$
\left(\begin{array}{l}
x \\
y \\
z
\end{array}\right) \mapsto\binom{\operatorname{det}^{r} M \cdot M \cdot\binom{x}{y}}{\operatorname{det} M \cdot z}
$$

Case 6.4. If $n=2 r$, then the reflection descends to $(x, y) \mapsto(x,-y)$, and

$$
\operatorname{Aut}^{\circ}\left(x^{2}-d y^{2}=z^{n+1}\right) \cong \mathrm{GO}\left(u^{2}-d v^{2}\right) / G \cong \mathbb{G}_{m} \times \mathrm{O}\left(x^{2}-d y^{2}\right)
$$

where the quotient map is given by $N \mapsto\left(\operatorname{det} N, \operatorname{det}^{-r} N \cdot N^{2 r}\right)$, with $(\lambda, M) \in$ $\mathbb{G}_{m} \times \mathrm{O}\left(x^{2}-d y^{2}\right)$ acting as

$$
\left(\begin{array}{l}
x \\
y \\
z
\end{array}\right) \mapsto\binom{\lambda^{r} \cdot M \cdot\binom{x}{y}}{\lambda \cdot z}
$$

In particular, the ind-group $\operatorname{Aut}_{\mathbb{C}}\left(x^{2}+y^{2}=z^{n}\right)$ is infinite dimensional, but its real form $\operatorname{Aut}_{\mathbb{R}}\left(x^{2}+y^{2}=z^{n}\right)$ is 2-dimensional. Similar examples are in Tot07. (Note that for a finite dimensional group, the dimension is the same over $\mathbb{R}$ and $\mathbb{C}$.)
Example 7. Let $2 \mathrm{I} \subset \mathrm{SL}_{2}(\mathrm{k})$ be the binary icosahedral group. Assume that char $k \nmid|2 \mathrm{I}|=120$. The ring of invariants is $k[x, y, z] /\left(x^{2}+y^{3}+z^{5}\right)$, where the degrees of $x, y, z$ are $30,20,12$.

Since $\mathrm{I} \subset \mathrm{PGL}_{2}$ is a maximal finite subgroup, its normalizer is itself. So $\mathbf{N}\left(2 \mathrm{I}, \mathrm{GL}_{2}\right)$ is the product of 2 I and of $\mathbf{C}\left(2 \mathrm{I}, \mathrm{GL}_{2}\right)$; the latter is the group of scalars $\mathbb{G}_{m}$. The diagonal matrix $\operatorname{diag}(c, c)$ acts on the invariants as

$$
\tau_{c}:(x, y, z) \mapsto\left(c^{30} x, c^{20} y, c^{12} z\right)
$$

However $\operatorname{diag}(-1,-1) \in 2 \mathrm{I}$, so the automorphism group is the $k$-points of $\mathbb{G}_{m} /\{ \pm 1\}$. As in AZ13] we get that

$$
\operatorname{Aut}\left(k[x, y, z] /\left(x^{2}+y^{3}+z^{5}\right)\right)=\left\{\tau_{c}^{\prime}:(x, y, z) \mapsto\left(c^{15} x, c^{10} y, c^{6} z\right)\right\} \cong k^{\times}
$$

Example 8. More generally, let $G \subset \mathrm{GL}_{n}$ be a finite, geometrically irreducible subgroup whose image in $\mathrm{PGL}_{n}$ is maximal among finite subgroups. Then $\mathbf{C}\left(G, \mathrm{GL}_{n}\right) \cong$ $\mathbb{G}_{m}$ surjects onto $\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G$, and so $\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G \cong \mathbb{G}_{m} /($ center of $G) \cong \mathbb{G}_{m}$.

If the assumptions of Corollary 4 also hold, then $\operatorname{Aut}\left(k[\mathbf{x}]^{G}\right) \cong k^{\times}$.
Example 9. Let $A$ be a commutative group scheme with a faithful representation on $k^{n}$ given by characters $\chi_{i}: A \rightarrow \mathbb{G}_{m}$. If $\chi_{1}, \ldots, \chi_{n-1}$ generate the whole character group of $A$, then there are infinitely many $\left(m_{1}, \ldots, m_{n}\right) \in \mathbb{N}^{n}$ such that $\chi_{1}^{m_{1}} \cdots \chi_{n-1}^{m_{n-1}}=\chi_{n}$. Then

$$
\left(x_{1}, \ldots, x_{n}\right) \mapsto\left(x_{1}, \ldots, x_{n-1}, x_{n}+c x_{1}^{m_{1}} \cdots x_{n-1}^{m_{n-1}}\right)
$$

commutes with $A$, and descends to an automorphism of $k[\mathbf{x}]^{A}$. Thus $\operatorname{Aut}\left(k[\mathbf{x}]^{A}\right)$ is infinite dimensional.

If $\chi_{1}, \ldots, \chi_{n-1}$ do not generate the whole character group, then there is an $a \in A$ such that $\left(\chi_{1}(a), \ldots, \chi_{n}(a)\right)$ is a pseudo-reflection.
Example 10. Consider 2 representations $G \rightarrow \mathrm{GL}(U)$ and $G \rightarrow \mathrm{GL}(V)$. Assume that there is a $G$-equivariant linear map $\phi: \operatorname{Sym}^{m}(U) \rightarrow V$. Let $p$ be a polynomial of degree $m$ on $U$. Then $(u, v) \mapsto(u, v+\phi(p(u)))$ is an automorphism of $U+V$ that commutes with the diagonal $G$-action.

If $G \hookrightarrow \mathrm{GL}(U)$, then there are nonzero $\phi: \operatorname{Sym}^{m}(U) \rightarrow V$ by KT23.
Example 11. Consider a finite subgroup $G \subset \mathrm{GL}_{n}$. Assume that there is a $G$ equivariant linear map $\phi: \operatorname{Sym}^{m}(V) \rightarrow V$ for some $m \geq 2$. Let $p$ be a polynomial of degree $m$ on $V$. Then $v \mapsto v+\phi(p(v))$ is an automorphism of $k[[\mathbf{x}]]$ that commutes with the $G$-action. (It is usually not an automorphism of $k[\mathbf{x}]$.)

For any $V$ there are infinitely many $\phi: \operatorname{Sym}^{m}(V) \rightarrow V$ by KT23.
Example 12. Let $k$ be a field of characteristic 2 and consider the $\mathbb{Z} / 2$-action

$$
\left(x_{1}, y_{1}, x_{2}, y_{2}\right) \mapsto\left(x_{1}, y_{1}+x_{1}, x_{2}, y_{2}+x_{2}\right)
$$

The invariants are

$$
u_{i}:=x_{i}, \quad v_{i}:=y_{i}\left(y_{i}+x_{i}\right), \quad \text { and } \quad w:=x_{1} y_{2}+x_{2} y_{1}
$$

They satisfy the equation

$$
w^{2}+u_{1} u_{2} w+u_{1}^{2} v_{2}+u_{2}^{2} v_{1}=0
$$

Consider the automorphism $\phi_{m}$ that fixes $u_{1}, u_{2}, w$ and sends

$$
\left(v_{1}, v_{2}\right) \mapsto\left(v_{1}+u_{1}^{m}, v_{2}+u_{2}^{2} u_{1}^{m-2}\right)
$$

Thus $\phi_{m}\left(y_{1}\left(y_{1}+x_{1}\right)\right)=y_{1}^{2}+y_{1} x_{1}+x_{1}^{m}$, and the right had side is irreducible for $m \geq 3$. So there is no automorphism of $k\left[x_{1}, y_{2}, x_{2}, y_{2}\right]$ that sends $y_{1}\left(y_{1}+x_{1}\right)$ to $y_{1}^{2}+y_{1} x_{1}+x_{1}^{m}$.

Thus the assumption char $k \nmid|G|$ is necessary in Theorems 1 and 25. It is not clear what happens for irreducible or birationally irreducible actions.

Commuting with pseudo-reflections is a strong restriction.
Example 13 (Actions with many pseudo-reflections). Any automorphism $\phi \in$ $\operatorname{Aut}\left(\mathbb{A}^{n}\right)$ that commutes with a pseudo-reflection fixes the invariant hyperplane. If there are $n$ such linearly independent hyperplanes $\left(x_{i}=0\right)$, then $\phi$ is an automorphism of $\mathbb{G}_{m}^{n} \cong \mathbb{A}^{n} \backslash\left(x_{1} \cdots x_{n}=0\right)$. Note that the units on $\mathbb{G}_{m}^{n}$ are the monomials in the $x_{i}$, so $\operatorname{Aut}\left(\mathbb{G}_{m}^{n}\right)$ maps monomials to monomials. The only ones that extend to $\operatorname{Aut}\left(\mathbb{A}^{n}\right)$ are $\left(x_{1}, \ldots, x_{n}\right) \mapsto\left(c_{1} x_{1}, \ldots, c_{n} x_{n}\right)$, where $c_{i} \in k^{\times}$.

If there are $n-1$ linearly independent hyperplanes $\left(x_{i}=0\right)$ for $i=1, \ldots, n-1$, then $\phi$ is an automorphism of $\mathbb{G}_{m}^{n-1} \times \mathbb{A}^{1} \cong \mathbb{A}^{n} \backslash\left(x_{1} \cdots x_{n-1}=0\right)$. Since any polynomial map $\mathbb{A}^{1} \rightarrow \mathbb{G}_{m}$ is constant, we see that $\phi$ is of the form

$$
\left(x_{1}, \ldots, x_{n}\right) \mapsto\left(c_{1} x_{1}, \ldots, c_{n-1} x_{n-1}, c_{n} x_{n}+p\left(x_{1}, \ldots, x_{n-1}\right)\right)
$$

where $c_{i} \in k^{\times}$and $p \in k\left[x_{1}, \ldots, x_{n-1}\right]$.
By contrast, many automorphisms are the identity on a codimension $\geq 2$ subset.
Example 14. Let $Z \subset \mathbb{A}^{n}$ be a closed subset of dimension $\leq n-2$. Let

$$
\pi:\left(x_{1}, \ldots, x_{n}\right) \mapsto\left(x_{1}, \ldots, x_{n-1}\right)
$$

be the projection and $W \subset \mathbb{A}^{n-1}\left(x_{1}, \ldots, x_{n-1}\right)$ the closure of the image of $Z$. Let $p\left(x_{1}, \ldots, x_{n-1}\right)$ be a polynomial that vanishes on $W$. Then

$$
\pi:\left(x_{1}, \ldots, x_{n}\right) \mapsto\left(x_{1}, \ldots, x_{n-1}, x_{n}+p\left(x_{1}, \ldots, x_{n-1}\right)\right)
$$

is an automorphism of $\mathbb{A}^{n}$ that is the identity on $Z$. They generate an infinite dimensional subgroup of $\mathbb{A}^{n}$ that is transitive on $\mathbb{A}^{n} \backslash Z$.

## 2. Lifting of Automorphisms

For the proof of Theorem 1, it is better to use geometric language. Thus let $\pi: Y \rightarrow X$ be morphism of $k$-schemes. We aim to understand which automorphisms of $X$ lift to automorphisms of $Y$.
15 (Basic set-up). Let $\pi: Y \rightarrow X$ be a finite, dominant morphism of geometrically irreducible and geometrically normal $k$-schemes. Let $Y^{\circ} \subset Y, X^{\circ} \subset X$ be nonsingular, dense, open subsets such that the restriction $\pi^{\circ}: Y^{\circ} \rightarrow X^{\circ}$ is a finite and étale morphism.

We study situations when one of the following assumptions holds.
(1) $Y_{\bar{k}}^{\circ}$ is simply connected.
(2) Every étale cover of $Y_{\bar{k}}^{\circ}$ of degree $\leq \operatorname{deg} \pi$ is trivial.
(3) Every Galois étale cover of $Y_{\bar{k}}^{\circ}$ of degree dividing $\operatorname{deg} \pi$ is trivial, and $\pi$ is Galois.
Our main interest is in $Y=\mathbb{A}_{k}^{n}:=\operatorname{Spec}_{k} k[\mathbf{x}]$ or $Y=\hat{\mathbb{A}}_{k}^{n}:=\operatorname{Spec}_{k} k[[\mathbf{x}]]$, and (1-3) are dictated by what holds for $Y^{\circ}:=Y \backslash Z$, where $Z$ is a closed subset of dimension $\leq n-2$. Then $Y^{\circ}$ satisfies one of $(1-3)$ in the following cases.
(4) If $Y=\mathbb{A}_{k}^{n}$ and char $k=0$, then (1) holds.
(5) If $Y=\hat{\mathbb{A}}_{k}^{n}$ and char $k$ arbitrary, then (1) holds.
(6) If char $k=p>0$ and $\operatorname{deg} \pi<p$, then (2) holds.
(7) char $k=p>0, \pi$ is Galois and $p \nmid \operatorname{deg} \pi$, then (3) holds.

To see this, note that if $Y$ is regular and $\operatorname{dim} Z \leq \operatorname{dim} Y-2$, then $\pi_{1}(Y \backslash Z)=\pi_{1}(Y)$ by Nagata's purity theorem (cf. Sta22, Tag 0BMB).

Next $\pi_{1}\left(\hat{\mathbb{A}}_{k}^{n}\right)=\{1\}$ over any separably closed field (see, for example, Sta22, Tag 04GE $]$ ). The Hurwitz formula shows that $\mathbb{A} \frac{1}{k}$ has no étale covers that are tamely ramified at infinity. Restricting a cover of $\mathbb{A} \frac{n}{k}$ to a general line through the origin gives the rest our claims.

The following obvious lifting result applies only to separably closed base fields.
Lemma 16. Using the notation of (15), assume that $Y^{\circ}$ is simply connected. Then every automorphisms of $X$ lifts to an automorphism of $Y$.

Proof. For $\phi \in \operatorname{Aut}(X)$, let $\tilde{Y}$ denote the normalization of the fiber product of $\pi: Y \rightarrow X$ and $\phi \circ \pi: Y \rightarrow X$. The first projection $\sigma: \tilde{Y} \rightarrow Y$ is étale over $Y^{\circ}$, hence $\tilde{Y}$ is a disjoint union of copies of $Y$ since $Y^{\circ}$ is simply connected. Each of these irreducible components gives a lifting.

17 (Multiplicity filtration). Let $(A, m)$ be a complete local $k$-algebra. The kernel of $\operatorname{Aut}_{k}(A) \rightarrow \mathrm{GL}\left(m / m^{2}\right)$ is unipotent. Thus any reducive subgroup of $\operatorname{Aut}_{k}(A)$ is also a subgroup of $\mathrm{GL}\left(\mathrm{m} / \mathrm{m}^{2}\right)$.

The problem is that in most cases the image of $\operatorname{Aut}_{k}(A) \rightarrow \mathrm{GL}\left(m / m^{2}\right)$ is much smaller than $\mathrm{GL}\left(m / m^{2}\right)$, and is hard to determine. For $A=k[[\mathbf{x}]]^{G}$, the generators of the maximal ideal are the minimal generators of the ring of invariants. In most cases these are not known, we do not even have good bounds on the dimension of $m / m^{2}$. We need to find a representation of $\operatorname{Aut}\left(k[[\mathbf{x}]]^{G}\right)$ that relates more directly to $G \subset \mathrm{GL}_{n}$.

We understand much better the multiplicity filtration of $k[[\mathbf{x}]]^{G}$. This is given as

$$
\begin{equation*}
I_{r}:=k\left[\left[x_{1}, \ldots, x_{n}\right]\right]^{G} \cap\left(x_{1}, \ldots, x_{n}\right)^{r} . \tag{17,1}
\end{equation*}
$$

That is, $I_{r}:=\left\{f:\right.$ mult $\left._{0} f \geq r\right\}$, where mult $_{0} f$ is the multiplicity at the orgin, when we view $f$ as an element of $k\left[\left[x_{1}, \ldots, x_{n}\right]\right]$.

Corollary 18. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced subgroup scheme without pseudo-reflections. Then $\operatorname{Aut}\left(k[[\mathbf{x}]]^{G}\right)$ preserves the multiplicity filtration.

Proof. It is enough to prove this over $\bar{k}$. Then every automorphisms of $k[[\mathbf{x}]]^{G}$ lifts to automorphisms of $k[[\mathbf{x}]]$ by Lemma 16 .

On $k\left[\left[x_{1}, \ldots, x_{n}\right]\right]$ the multiplicity filtration is the same as the filtration by the powers of the maximal ideal, so preserved by all automorphisms. Thus the same holds for $k[[\mathbf{x}]]^{G}$.

We can now prove parts of Theorem 1 .
Corollary 19. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced subgroup scheme without pseudo-reflections. Then

$$
\begin{equation*}
\text { Aut }^{\text {graded }}\left(k[\mathbf{x}]^{G}\right) \cong\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k) \tag{19,1}
\end{equation*}
$$

Proof. Let $k^{s} \supset k$ be a separable closure. Since $k[[\mathbf{x}]]^{G}$ is the completion of $k[\mathbf{x}]^{G}$, every graded automorphism $\phi$ of $k[\mathbf{x}]^{G}$ has a natural extension to an automorphism of $k[[\mathbf{x}]]^{G}$, hence lifts to an automorphism $\bar{\phi}$ of $k^{s}[[\mathbf{x}]]$ by Lemma 16 and (15, 4). Since $\bar{\phi}$ preserves the powers of the maximal ideal, it induces an automorphism of
the corresponding graded ring. Thus we get $\tilde{\phi} \in \mathrm{Aut}^{\text {graded }} k^{s}[\mathbf{x}] \cong \mathrm{GL}_{n}\left(k^{s}\right)$. This shows that

$$
\text { Aut }^{\text {graded }}\left(k^{s}[\mathbf{x}]^{G}\right) \cong\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\left(k^{s}\right)\right) / G\left(k^{s}\right)\right.
$$

(19, 2)
All this is $\operatorname{Gal}\left(k^{s} / k\right)$-equivariant, and, by definition., $\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k)$ is the $\operatorname{group}$ of $\operatorname{Gal}\left(k^{s} / k\right)$-fixed points of $\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\left(k^{s}\right)\right) / G\left(k^{s}\right)\right.$.
Corollary 20. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced subgroup scheme without pseudo-reflections. Then there is a split exact sequence

$$
\begin{equation*}
1 \rightarrow \operatorname{Aut}^{\mathrm{u}}\left(k[[\mathbf{x}]]^{G}\right) \rightarrow \operatorname{Aut}\left(k[[\mathbf{x}]]^{G}\right) \rightarrow\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k) \rightarrow 1 \tag{20,1}
\end{equation*}
$$

Here $\operatorname{Aut}^{\mathrm{u}}\left(k[[\mathbf{x}]]^{G}\right)$ denotes the subgroup of those automorphisms that stabilize the multiplicity filtration $\left\{I_{r}\right\}$ of (17, 1) and act trivially on the graded pieces $I_{r} / I_{r+1}$. On the right hand side, $\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k)$ is as in (113).

Proof. By Corollary [18, $\operatorname{Aut}\left(k[[\mathbf{x}]]^{G}\right)$ preserves the multiplicity filtration. Thus we get an exact sequence

$$
\begin{equation*}
1 \rightarrow \operatorname{Aut}^{\mathrm{u}}\left(k[[\mathbf{x}]]^{G}\right) \rightarrow \operatorname{Aut}\left(k[[\mathbf{x}]]^{G}\right) \rightarrow \operatorname{Aut}^{\operatorname{graded}}\left(\oplus_{r \geq 0} I_{r} / I_{r+1}\right) \tag{20,2}
\end{equation*}
$$

Next observe that $\oplus_{r \geq 0} I_{r} / I_{r+1} \cong k[\mathbf{x}]^{G}$ and

$$
\text { Aut }^{\text {graded }}\left(k[\mathbf{x}]^{G}\right) \cong\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k)
$$

by Corollary 19. Finally $k[[\mathbf{x}]]^{G}$ is the completion of $k[\mathbf{x}]^{G}$, thus every graded automorphism of $k[\mathbf{x}]^{G}$ has a natural extension to an automorphism of $k[[\mathbf{x}]]^{G}$. This gives the splitting of $\operatorname{Aut}\left(k[[\mathbf{x}]]^{G}\right) \rightarrow\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k)$.
Remark 21. Let $(X, x)$ be a klt singularity over a field of characteristic 0 . By XZ21] there is a unique valuation centered at $x$ that minimizes the normalized volume. The corresponding filtration on $\mathcal{O}_{X}$ is thus invariant under $\operatorname{Aut}(X, x)$. This is interesting when this filtration is not equivalent to the 'powers of the maximal ideal' filtration. This happens for most quotient singularities.

In our case $G$ acts on $\mathbb{A}^{n}$ and on the blow-up $B_{0} \mathbb{A}^{n}$. Let the quotients be $\pi: Y_{G} \rightarrow X_{G}$ with exceptional divisor $E \cong \mathbb{P}^{n-1} / G$. This $E$ gives the normalized volume minimizer by [LX20, 7.1.1], giving the multiplicity filtration.

As a side remark, note that going from $X_{G}$ to $Y_{G}$ might be a step in a resolution algorithm for quotient singularities. However, as noted in Kol07, 2.29], repeating it need not give a resolution. For example, starting with the $\mathbb{Z}_{5}$-quotient with resolution dual graph

$$
2-3
$$

the $E \subset Y_{G}$ is the $(-1)$-curve in

$$
3-2-1-5
$$

so we see the same singularity on $Y_{G}$ that we started with.

## 3. Lifting unipotent automorphisms

The previous lifting results work well for separably close fields. Over general fields not all automorphisms lift, but we aim to show that all unipotent automorphisms lift.
Proposition 22. Using the notation and assumptions of (15.1-3), assume that $Y^{\circ}(k)$ is nonempty, and set $L:=\pi\left(Y^{\circ}(k)\right)$. For $\phi \in \operatorname{Aut}\left(X^{\circ}\right)$ the following are equivalent.
(1) $\phi$ lifts to $\phi_{Y} \in \operatorname{Aut}\left(Y^{\circ}\right)$.
(2) $\phi(L)=L$.
(3) $\phi(L) \cap L \neq \emptyset$.

Proof. (1) $\Rightarrow(2) \Rightarrow(3)$ are clear.
Next let $\tilde{Y}$ denote the normalization of the fiber product of $\pi: Y \rightarrow X$ and $\phi \circ \pi: Y \rightarrow X$. The first projection $\sigma: \tilde{Y} \rightarrow Y$ is étale over $Y^{\circ}$. Liftings of $\phi$ are in one-to-one correspondence with sections of $\sigma: \tilde{Y} \rightarrow Y$.

Note that (3) holds iff there are $y_{1}, y_{2} \in Y^{\circ}(k)$ such that $\pi\left(y_{1}\right)=\phi \circ \pi\left(y_{2}\right)$. Then $\left(y_{1}, y_{2}\right) \in \tilde{Y}(k)$. Let $W \subset \tilde{Y}$ be the unique irreducible component containing $\left(y_{1}, y_{2}\right)$. It has a smooth $k$-point, namely $\left(y_{1}, y_{2}\right)$, so it is geometrically irreducible. The assumptions (15, 1-3) all guarantee that $\sigma^{\circ}: W^{\circ} \rightarrow Y^{\circ}$ is an isomorphism over $\bar{k}$, hence an isomorphism.

For finitely generated fields, $Y^{\circ}(k) \rightarrow\left(Y^{\circ} / G\right)(k)$ is rarely surjective. The following version of Proposition 22 gives many more cases.

Proposition 23. We use the notation and assumptions of (15.1-3), and fix $\phi \in$ $\operatorname{Aut}(X) \cap \operatorname{Aut}\left(X^{\circ}\right)$. Let $D \subset X \backslash X^{\circ}$ be a geometrically irreducible divisor, and $E \subset$ $\pi^{-1}(D)$ a geometrically irreducible component. Assume that $\pi$ is tamely ramified along $E$, and $\phi$ is the identity on $\mathcal{O}_{X} / \mathcal{O}_{X}(-2 D)$.

Then there is a unique lifting of $\phi$ to $\phi_{Y} \in \operatorname{Aut}(Y)$ such that $\phi_{Y}$ is the identity on $\mathcal{O}_{Y} / \mathcal{O}_{Y}(-2 E)$.

Proof. As in the proof of Proposition 22, let $\tilde{Y}$ denote the normalization of the fiber product of $\pi: Y \rightarrow X$ and $\phi \circ \pi: Y \rightarrow X$. Set $L:=k(D)$ and $K:=k(E)$. We claim that $e: \operatorname{Spec} K \hookrightarrow Y$ lifts to $\tilde{e}: \operatorname{Spec} K \hookrightarrow \tilde{Y}$.

To see this, let $R_{X}$ (resp. $R_{Y}$ ) be the completion of the local ring at the generic point of $D$ (resp. $E$ ). Then $R_{X} \cong L[[s]], R_{Y} \cong K[[t]]$ and $\pi^{*} s=t^{r}$ (unit) for some $r$ not divisible by char $L$. Write the unit as $c(1+t w(t))$ for some power series $w(t)$. We can replace $t$ by $t / \sqrt[r]{1+t w(t)}$ to get the simpler form $\pi^{*} s=c t^{r}$ for some $c \in K$. So $R_{Y} \cong K[[s]][t] /\left(c t^{r}-s\right)$.
$\phi^{*} s$ is a power series in $s$, which has the form $\phi^{*} s=s(1+s v(s))$ for some power series $v(s) \in L[[s]]$. The rest is a direct algebra computation, see Lemma 24.

Let $W \subset T$ be the unique irreducible component containing $\tilde{e}(\operatorname{Spec} K)$. It has a nonsingular, geometrically irreducible point, so it is geometrically irreducible. The assumptions (15) 1-3) all guarantee that $\sigma: W \rightarrow Y$ is an isomorphism over $\bar{k}$, hence an isomorphism. Our choice in (24) gives that $\phi_{Y}$ is the identity on $\mathcal{O}_{Y} / \mathcal{O}_{Y}(-(r+1) E)$.

Lemma 24. Let $K / L$ be a finite field extension and $v(s) \in L[[s]]$ a power series. Assume that char $L \nmid r$. Let $B$ be the normalization of

$$
K[[s]][x] /\left(c x^{r}-s\right) \otimes_{L[[s]]} K[[s]][y] /\left(c y^{r}-s-s^{2} v(s)\right) .
$$

Then there is a quotient map $q: B \rightarrow K[[s]][u] /\left(c u^{r}-s\right)$ such that

$$
q(x \otimes 1-1 \otimes y) \in(s u)
$$

Proof. Since char $L \nmid r, \sqrt[r]{1+s v(s)}$ is a power series. Setting $y=z \sqrt[r]{1+s v(s)}$, we get that

$$
K[[s]][x] /\left(c x^{r}-s\right) \otimes_{L[[s]]} K[[s]][z] /\left(c z^{r}-s\right) \cong\left(K \otimes_{k} K\right)[[x, z]] /\left(c x^{r}-c z^{r}\right)
$$

This has a quotient $K[[x, z]] /(x-z) \cong K[[x]] \cong K[[s]][u] /\left(c u^{r}-s\right)$, which is still a quotient after normalization.

Note 24.2. If $\phi$ is the identity on $D$, then $\phi^{*} s=b s(1+s v(s))$ for some $b \in L$, and then in (24) 1) we need to normalize $\left(K \otimes_{k} K\right)[[x, z]] /\left(x^{r}-b z^{r}\right)$. This involves $\sqrt[r]{b}$, and $\operatorname{Spec} K \hookrightarrow X$ lifts iff $\sqrt[r]{b} \in K$. So we really need $\phi$ to be the identity on $\mathcal{O}_{X} / \mathcal{O}_{X}(-2 D)$, not just on $\mathcal{O}_{X} / \mathcal{O}_{X}(-D)$.

We can now show that that every automorphism in $\operatorname{Aut}^{\mathrm{u}}\left(k[\mathbf{x}]^{G}\right)$ lifts uniquely to an automorphism in $\operatorname{Aut}^{\mathrm{u}}(k[\mathbf{x}])$.

Theorem 25. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced subgroup scheme without pseudo-reflections. Then
(1) $\operatorname{Aut}^{\mathrm{u}}\left(\hat{\mathbb{A}}_{k}^{n} / G\right)=C\left(G, \operatorname{Aut}^{\mathrm{u}}\left(\hat{\mathbb{A}}_{k}^{n}\right)\right)$, and
(2) $\operatorname{Aut}^{\mathrm{u}}\left(\mathbb{A}_{k}^{n} / G\right)=C\left(G, \operatorname{Aut}^{\mathrm{u}}\left(\mathbb{A}_{k}^{n}\right)\right)$ if $\operatorname{char} k \nmid|G|$.

Proof. We discuss (2). The same argument applies to $\hat{\mathbb{A}}_{k}^{n}$, here the assumption char $k \nmid|G|$ is not necessary since (15,5) is stronger than (15,4).

Let $\pi: B_{0} \mathbb{A}_{k}^{n} \rightarrow \mathbb{A}_{k}^{n}$ denote the blow-up of the origin with exceptional divisor $E \cong \mathbb{P}^{n-1}$. The $G$-action lifts to $B_{0} \mathbb{A}_{k}^{n}$. Taking the quotient we get $\pi_{G}: B_{0} \mathbb{A}_{k}^{n} / G \rightarrow$ $\mathbb{A}_{k}^{n} / G$.
$B_{0} \mathbb{A}_{k}^{n} / G$ is also obtained by blowing up the multiplicity filtration $I_{r}$ of (17, 1), which is invariant under $\operatorname{Aut}\left(\mathbb{A}_{k}^{n} / G\right)$ by Corollary 18. Therefore every automorphism $\phi \in \operatorname{Aut}^{\mathrm{u}}\left(\mathbb{A}_{k}^{n} / G\right)$ lifts to an automorphism $\phi_{B} \in \operatorname{Aut}\left(B_{0} \mathbb{A}_{k}^{n} / G\right)$ that acts trivially on $E / G$.

We need to show that $\phi_{B}$ lifts to $\tilde{\phi}_{B} \in \operatorname{Aut}^{u}\left(\mathbb{A}_{k}^{n}\right)$. The easy case is when $G$ does not contain scalars. In this case the $G$-action on $E$ is faithful, so $\pi_{G}$ is also étale in codimension 1.

If, in addition, $k$ is infinite, then there is a point $p \in E \cong \mathbb{P}^{n-1}$ where $\pi_{G}$ is étale. then $\phi_{B}\left(\pi_{G}(p)\right)=\pi_{G}(p)$, so the lifting is guaranteed by Proposition 22,

In general we aim to apply Proposition 23 with $D=E / G$. For this we need to know that $\phi_{B}$ is trivial on the first order neighborhood of $D$. This is discussed next.
26. More generally, let $X=\operatorname{Spec} R$ be an integral scheme and $x \in X$ a closed point with maximal ideal sheaf $m$. Let $\mathcal{I}:=\left\{R=: I_{0} \supset I_{1} \supset \cdots\right\}$ be a submultiplicative sequence of $m$-primary ideals, that is, $I_{a} \cdot I_{c} \subset I_{a+c}$. The blow-up is $B_{\mathcal{I}} X:=\operatorname{Proj}_{X}\left(\oplus_{j} t^{j} I_{j}\right)$, where $t$ is a formal variable and $\operatorname{deg}\left(t^{j} I_{j}\right)=j$.

The corresponding graded ring is $\mathrm{gr}_{\mathcal{I}} R:=\oplus_{j} t^{j}\left(I_{j} / I_{j+1}\right)$. Its proj, denoted by $E_{\mathcal{I}}$, is the exceptional divisor of $B_{\mathcal{I}} X \rightarrow X$.

Assume now that $\phi \in \operatorname{Aut}(X)$ stabilizes $\mathcal{I}$, acts trivially on $\operatorname{gr}_{\mathcal{I}} R$, and the latter is an integral domain.

Let $r$ be the smallest integer such that there is an $x \in I_{r} \backslash I_{r+1}$. Then $t^{r} x \in t^{r} I_{r}$ is not a zerodivisor on $E_{\mathcal{I}}$. The $\left(t^{r} x \neq 0\right)$ chart of the blow-up can be identified with the spectrum of $S:=R\left[\cup_{j} x^{-j} I_{r j}\right]$, viewed as a subring of the fraction field of $R$. In particular, $m S=x S$ is a principal ideal. That is, $(x=0)$ is a defining equation of the exceptional divisor in this chart.

Since the $\phi$-action is trivial on $x R / I_{r+1}$, it is trivial on $x R /(x m)$, hence the lifted $\phi$-action is trivial on $x S /(x m S)$, which is the restriction of $\mathcal{O}_{B_{\mathcal{I}} X}(-D) / \mathcal{O}_{B_{\mathcal{I} X}}(-2 D)$ to our chart.

The next example shows that the assumption $p \nmid|G|$ in (25),2) -and hence in (15) 3) -is necessary.

Example 27. Let $\pi: Y \rightarrow X$ be the Artin-Schreier cover of $X:=\mathbb{A}^{n}\left(x_{1}, \ldots, x_{n}\right)$ given by $y^{p}-y-x_{1}=0$. Then $Y=\mathbb{A}^{n}\left(y, x_{2}, \ldots, x_{n}\right)$ and $\pi$ is the quotient by the free $\mathbb{Z} / p$ action $\left(y, x_{2}, \ldots, x_{n}\right) \mapsto\left(y+1, x_{2}, \ldots, x_{n}\right)$.

Two Artin-Schreier field extensions $K(y) /\left(y^{p}-y-a_{i}\right)$ are isomorphic iff $a_{2}-a_{1}=$ $b^{p}-b$ for some $b \in K$. This shows that the covers given by $y^{p}-y-x_{1}=0$ and $y^{p}-y-c x_{1}=0$ are not isomorphic if $c \neq 1$. Thus the automorphisms $\left(x_{1}, x_{2}, \ldots, x_{n}\right) \mapsto\left(c x_{1}, x_{2}, \ldots, x_{n}\right)$ do not lift to $Y$.

28 (Proof of Theorem (1). For $k[[\mathbf{x}]]$, Corollary 20 gives the split exact sequence

$$
\begin{equation*}
1 \rightarrow \operatorname{Aut}^{\mathrm{u}}\left(k[[\mathbf{x}]]^{G}\right) \rightarrow \operatorname{Aut}\left(k[[\mathbf{x}]]^{G}\right) \rightarrow\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k) \rightarrow 1 \tag{28,1}
\end{equation*}
$$

Next Theorem 25, 1 gives $\operatorname{Aut}^{\mathrm{u}}\left(k[[\mathbf{x}]]^{G}\right) \cong C\left(G, \operatorname{Aut}^{\mathrm{u}}(k[[\mathbf{x}]])\right)$. These together give (1).

For $k[\mathbf{x}]$, first we observe that every automorhism of $k\left[x_{1}, \ldots, x_{n}\right]^{G}$ stabilizes the ideal $\left(x_{1}, \ldots, x_{n}\right) \cap k\left[x_{1}, \ldots, x_{n}\right]^{G}$ by Lemma 29, hence extends to an automorphism of $k[[\mathbf{x}]]^{G}$. Thus $(28,1)$ gives the split exact sequence

$$
\begin{equation*}
1 \rightarrow \operatorname{Aut}^{\mathrm{u}}\left(k[\mathbf{x}]^{G}\right) \rightarrow \operatorname{Aut}\left(k[\mathbf{x}]^{G}\right) \rightarrow\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(k) \rightarrow 1 \tag{28,2}
\end{equation*}
$$

The required identification of $\operatorname{Aut}^{\mathrm{u}}\left(k[\mathbf{x}]^{G}\right)$ is now given by Theorem 25,2 , which needs the assumption char $k \nmid|G|$.

Lemma 29. Let $k$ be a field and $G \subset \mathrm{GL}_{n}$ a finite, geometrically reduced subgroup scheme without pseudo-reflections. Assume that $0 \in k^{n}$ is the only $G$-invariant vector. Then every automorhism of $k\left[x_{1}, \ldots, x_{n}\right]^{G}$ stabilizes the ideal $\left(x_{1}, \ldots, x_{n}\right) \cap$ $k\left[x_{1}, \ldots, x_{n}\right]^{G}$.

Proof. It is enough to prove this when $k$ is algebraically closed. Let $X:=$ $\operatorname{Spec}_{k} k\left[x_{1}, \ldots, x_{n}\right]^{G}, p \in X$ a closed point and $\bar{p} \in \mathbb{A}^{n}$ a preimage of $p$. Let $\hat{X}_{p}$ denote the completion of $X$ at $p$. Then the fundamental group of $\hat{X}_{p} \backslash \operatorname{Sing} X$ is the stabilizer of $\bar{p}$. By assumption, the origin is the only point whose stabilizer is $G$.

## 4. Normalizers of finite subgroups of $\operatorname{Aut}\left(\mathbb{A}_{k}^{n}\right)$

Fix a field $k$ and let $G \subset \mathrm{GL}_{n}$ be a geometrically reduced subgroup scheme, where now we view $\mathrm{GL}_{n}$ as an algebraic group over $k$ that acts linearly on affine $n$-space $\mathbb{A}_{k}^{n}$. We aim to understand when the centralizer $C\left(G, \operatorname{Aut}\left(\mathbb{A}_{k}^{n}\right)\right)$ is small.

The following result, modeled on Jel94, Tot07, is somewhat complicated, but turns out to apply in many cases.

Theorem 30. Let $G \subset \mathrm{GL}_{n}$ be a geometrically reduced $k$-subgroup scheme and $\phi \in \operatorname{Aut}\left(\mathbb{A}_{k}^{n}\right)$ an automorphism that commutes with $G$. Then
(1) either $\phi$ extends to an automorphism of $\mathbb{P}_{k}^{n}$, hence $\phi \in \mathrm{GL}_{n}(k)$,
(2) or there are G-equivariant rational maps

$$
\left(G \curvearrowright \mathbb{P}_{k}^{n-1}\right) \stackrel{\tau}{\sim}\left(G \curvearrowright\left(\mathbb{P}_{k}^{r} \times Z\right)\right) \xrightarrow{\pi}(G \curvearrowright Z) \xrightarrow{\sigma}\left(G \curvearrowright \mathbb{P}_{k}^{n-1}\right)
$$

where $\tau$ is birational, $r \geq 1$, and $\pi$ is the coordinate projection.
Note that the $G$-action on $\mathbb{P}_{k}^{r} \times Z$ may be only rational, and the first projection $\mathbb{P}_{k}^{r} \times Z \rightarrow \mathbb{P}_{k}^{r}$ need not be $G$-equivariant.

Proof. $\phi$ extends to a birational map $\bar{\phi}: \mathbb{P}_{s}^{n} \rightarrow \mathbb{P}_{t}^{n}$; we use the subscripts source/target to distinguish them. Let $W$ be the closed graph of $\bar{\phi}$, with coordinate projections $p_{s}, p_{t}: W \rightarrow \mathbb{P}^{n}$. Thus $\bar{\phi}=p_{t} \circ p_{s}^{-1}$. Let $H_{s} \subset \mathbb{P}_{s}^{n}$ be the hyperplane at infinity.

If the restriction of $p_{t}$ to $\left(p_{s}^{-1}\right)_{*}\left(H_{s}\right) \rightarrow H_{t}$ is birational, then $\bar{\phi}$ is a local isomorphism at the generic points of $H_{s}$ and $H_{t}$. Then $\bar{\phi}$ is an isomorphism by (MM64; see also Kol23, 11.39] for a more general version.

Otherwise, by a result of Zariski and Abhyankar (see for example [KM98, 2.45]) there is a sequence of $G$-equivariant blow-ups

$$
X_{m} \rightarrow X_{m-1} \rightarrow \cdots \rightarrow X_{0}=\mathbb{P}_{t}^{n}
$$

such that the birational transform of $H_{s} \cong \mathbb{P}_{k}^{n-1}$ on $X_{m}$ is the exceptional divisor of the last blow-up $X_{m} \rightarrow X_{m-1}$. Let $Z \subset X_{m-1}$ be the center of this blow-up. Then we get (2).

Complement 30. 3. The proof shows that in 30.2.a) the kernel of $G \rightarrow \operatorname{Bir}(Z)$ acts linearly on $\mathbb{P}_{k(Z)}^{r}$.

We turn (30, 2.a) into a definition.
Definition 31. Let $k$ be a field and $G \curvearrowright \mathbb{P}_{k}^{m}$ a group scheme acting on $\mathbb{P}_{k}^{m}$. For $m \geq 2$ the action is birationally reducible if there are $G$-equivariant rational maps

$$
\begin{equation*}
\left(G \curvearrowright \mathbb{P}_{k}^{m}\right) \stackrel{\tau}{\sim}\left(G \curvearrowright\left(\mathbb{P}_{k}^{r} \times Z\right)\right) \xrightarrow{\pi}(G \curvearrowright Z), \tag{31,1}
\end{equation*}
$$

where $\tau$ is birational, $0<r<m$, and $\pi$ is the coordinate projection. Note that the $G$-action on $\mathbb{P}_{k}^{r} \times Z$ may be only rational.

Otherwise $G \curvearrowright \mathbb{P}_{k}^{m}$ is birationally irreducible. Clearly, if $H \subset G$ is a subgroup, and $H \curvearrowright \mathbb{P}_{k}^{m}$ is birationally irreducible, then so is $G \curvearrowright \mathbb{P}_{k}^{m}$.

For $G \subset \mathrm{GL}_{m+1}$, let $G \curvearrowright \mathbb{P}_{k}^{m}$ be the induced action. If the $G$-action has an invariant subspace of codimension $\geq 2$, then $G \curvearrowright \mathbb{P}_{k}^{m}$ is birationally reducible by (33, 1).

If $m=1$ then $0<r<m$ is impossible. So we call $G \curvearrowright \mathbb{P}_{k}^{1}$ birationally reducible iff it has a fixed point. (This is done mainly to make Corollary 32 work out.)

Comment. This definition suits our current needs, but there are other versions that may be more natural.

Requiring $Z \cong \mathbb{P}^{m-r}$ would be a closer analog of the notion of reducible linear representation. In general $\mathbb{P}_{k}^{m} \sim \mathbb{P}_{k}^{r} \times Z$ does not imply that $Z \sim \mathbb{P}_{k}^{m-r}$ [BCTSSD85, but I do not know such examples that arise from automorphisms.

Putting together the definition with Theorem 30 gives the following.
Corollary 32. Let $G \subset \mathrm{GL}_{n}$ be a geometrically reduced $k$-subgroup scheme whose induced action on $\mathbb{P}_{k}^{n-1}$ is birationally irreducible. Then
(1) $N\left(G, \operatorname{Aut}^{\mathrm{u}}\left(\mathbb{A}_{k}^{n}\right)\right)=C\left(G, \operatorname{Aut}^{\mathrm{u}}\left(\mathbb{A}_{k}^{n}\right)\right)=\{1\}$, and
(2) $N\left(G, \operatorname{Aut}\left(\mathbb{A}_{k}^{n}\right)\right)=N\left(G, \mathrm{GL}_{n}\right)$.

Proof. Let $\phi \in C\left(G, \operatorname{Aut}\left(\mathbb{A}_{k}^{n}\right)\right)$. We need to show that $\phi \in \mathrm{GL}_{n}$. If this is not the case, then, by Theorem 30, we get $G$-equivariant rational maps as in (30, 2.a). Here $r<n-1$ is impossible since $G \curvearrowright \mathbb{P}_{k}^{n-1}$ is birationally irreducible. Thus $r=n-1, Z$ is a point and $\sigma(Z) \in \mathbb{P}_{k}^{n-1}$ is a $G$-fixed point.

For $n \geq 3$, a birationally irreducible action has no fixed points by (33, 1). For $n=2$ there are no fixed points by definition.

Birational irreducibility is only a sufficient condition, but, by Example 10, linear irreducibility is almost necessary for Corollary 32 ,

Next we give examples of actions that are birationally reducible or are known to be birationally irreducible.
Example 33. The following are birationally reducible actions on $\mathbb{P}_{k}^{n}$. Here it is more natural to use the classical convention that $\mathbb{P}(V)$ is the projective space of all lines through the origin of $V$.
(33) 1) Assume that $G \subset \mathrm{GL}(V)$ is reducible with invariant subspace $W$ of codimension $\geq 2$. Projecting $\mathbb{P}(V)$ from $\mathbb{P}(W)$ gives that

$$
(G \curvearrowright \mathbb{P}(V)) \stackrel{\tau}{\sim}(G \curvearrowright(\mathbb{P}(W+k) \times \mathbb{P}(V / W)))
$$

If $W$ has codimension 1 and the characteristic is 0 , then it has a 1-dimensional $G$-invariant complement, so $G \curvearrowright \mathbb{P}(V)$ is birationally reducible once $\operatorname{dim} V \geq 3$.

See Proposition 40 for a birationally irreducible action with a codimension 1 invariant subspace in positive characteristic.
(33)2) Assume that $G \subset \mathrm{GL}(V)$ is irreducible but imprimitive, thus it preserves a direct sum decomposition $V=\oplus_{i=1}^{r} V_{i}$. Assume that $\operatorname{dim} V_{i}>1$. We get $\mathbb{P}\left(V_{i}\right) \subset$ $\mathbb{P}(V)$. Note that a general point $p \in \mathbb{P}(V)$ is contained in a unique linear space $L(p)$ of dimension $r-1$ that meets each $\mathbb{P}\left(V_{i}\right)$. Thus we get that

$$
(G \curvearrowright \mathbb{P}(V)) \stackrel{\tau}{\sim}\left(G \curvearrowright\left(\mathbb{P}\left(k^{r}\right) \times \prod_{i} \mathbb{P}\left(V_{i}\right)\right)\right)
$$

See (34, 5 ) for the $\operatorname{dim} V_{i}=1$ case.
(33)3) With a little more care, the previous construction also works if the $V_{i}$ are conjugate over $k$. We need to replace the factor $\prod_{i} \mathbb{P}\left(V_{i}\right)$ with the Weil restriction of $\mathbb{P}\left(V_{1}\right)$.
(33) 4) The permutation representation of $S_{n+2}$ and $A_{n+2}$ in $\mathrm{GL}_{n+1}$ is irreducible and primitive, but birationally reducible.

More generally, assume that $G \curvearrowright \mathbb{P}_{k}^{n}$ has an orbit $W$ of $n+2$ points in linearly general position. Let $p \in \mathbb{P}^{n}$ be a general point. Then there is a unique rational normal curve (of degree $n$ ) passing through $W \cup\{p\}$ (see, for example, [Har95, 1.18]). This gives a $G$-equivariant morphism $\mathbb{P}_{k}^{n} \rightarrow Z$, whose fibers are the rational normal curves passing through $W$. The $n=3$ case is worked out in Pro10, 4.7].

If $n$ is odd, or if one of the $n+2$ points is a $k$-point, then $\mathbb{P}_{k}^{n} \rightarrow Z$ is a product birationally, giving

$$
\left(G \curvearrowright \mathbb{P}_{k}^{n}\right) \stackrel{\tau}{\sim}\left(G \curvearrowright\left(\mathbb{P}_{k}^{1} \times Z\right)\right)
$$

If $n$ is even, then $\mathbb{P}_{k}^{n} \rightarrow Z$ need not be a product birationally. For $n=2$ there are some birationally irreducible cases; this can be proved as in Proposition 43, Most likely there are birationally irreducible cases for all even values of $n$.

Example 34. The following are birationally irreducible actions on $\mathbb{P}_{k}^{n}$.
(34)1) By definition $G \curvearrowright \mathbb{P}_{k}^{1}$ is birationally irreducible iff $G$ has no fixed points over $k$.
(34)2) If $G \curvearrowright \mathbb{P}_{k}^{n}$ is birationally rigid, then it is also birationally irreducible; see Definition 39
(34,3) By Sak19, $G \subset \mathrm{PGL}_{3}(\mathbb{C})$ is birationally rigid iff $G$ is irreducible and $G \not \approx A_{4}, G \neq S_{4}$.
(34) 4) By CS19, $G \subset \mathrm{PGL}_{4}(\mathbb{C})$ is birationally rigid iff $G$ is irreducible, primitive, and $G \not \approx A_{5}, G \not \approx S_{5}$.
(34)5) There are many other cases that are not $G$-birationally rigid, but still birationally irreducible. See $\left[\mathrm{CS} 22\right.$ for such subgroups of $\mathrm{PGL}_{4}(\mathbb{C})$.
(34)6) Let $G$ be a group acting on $\mathbb{P}_{k}^{n}$ that can not act on a rationally connected $(n-1)$-fold over $k$. Then $G \curvearrowright \mathbb{P}_{k}^{n}$ is birationally irreducible.

In positive characteristic, this applies to $\operatorname{PSL}_{n}\left(\mathbb{F}_{q}\right)$ and $\operatorname{PSU}_{n}\left(\mathbb{F}_{q}\right)$ for $n=3,4$, with finitely many exceptions.

The orthogonal groups $\mathrm{PSO}_{n}\left(\mathbb{F}_{q}\right)$ act on a quadric hypersurface in $\mathbb{P}^{n-1}$ by definition, so the above argument does not apply. See Corollary 36 for birationally irreducible cases.

For $k=\mathbb{C}$ and $n=4$ we have actions of $\operatorname{PSp}_{4}\left(\mathbb{F}_{3}\right)$ and $\mathrm{PSL}_{2}\left(\mathbb{F}_{11}\right)$, see HM01. However, these groups both have invariant Fano hypersurfaces, see Pro12. The examples in Tie16, 3.6] are possible candidates. However, [Tie16] suggests that there may be only few such examples in high dimensions.

More birationally irreducible examples are obtained using Lemmas 46, 48.
Proposition 35. $\operatorname{PSL}_{n}\left(\mathbb{F}_{q}\right) \curvearrowright \mathbb{P}_{\mathbb{F}_{q}}^{n-1}$ is birationally irreducible if $q \neq 2$.
Proof. Assume that we have $\operatorname{PSL}_{n}\left(\mathbb{F}_{q}\right) \curvearrowright\left(\mathbb{P}_{\mathbb{F}_{q}}^{r} \times Z\right)$. For some prime $\ell \neq \operatorname{char} \mathbb{F}_{q}$, the maximal torus gives a subgroup $H \cong\left(\mu_{\ell}\right)^{n-1}$ to which Lemma 48 applies. Since $\mathrm{PSL}_{n}\left(\mathbb{F}_{q}\right)$ is simple, its action on $Z$ is either trivial or faithful. The latter is impossible by Lemma 48. Then, by (30 3) we get a faithful, linear $\mathrm{PSL}_{n}\left(\mathbb{F}_{q}\right)$-action on $\mathbb{P}_{\mathbb{F}_{q}}^{r}$ for $r<n-1$, which is again impossible.

Proposition 36. Let $q$ be the power of an odd prime and $n \geq 5$. Then
(1) $\mathrm{PO}_{n}\left(\mathbb{F}_{q}\right) \curvearrowright \mathbb{P}^{n-1}$ is birationally irreducible.
(2) If $n$ is odd then $\mathrm{PSO}_{n}^{+}\left(\mathbb{F}_{q}\right) \curvearrowright \mathbb{P}^{n-1}$ is also birationally irreducible.

Here $\mathrm{PSO}_{n}^{+}\left(\mathbb{F}_{q}\right) \subset \mathrm{PSO}_{n}\left(\mathbb{F}_{q}\right)$ denotes the subgroup of elements with spinor norm 1. It is a simple subgroup of index 2.

Proof. The diagonal group $\mu_{2}^{n}$ is in $\mathrm{O}_{n}\left(\mathbb{F}_{q}\right)$. So $\mu_{2}^{n-1}$ is a subgroup of $\mathrm{PO}_{n}\left(\mathbb{F}_{q}\right)$, and we get the first claim as in the proof of Proposition 35 ,

If $n$ is odd then $\mathrm{PSO}_{n}\left(\mathbb{F}_{q}\right)=\mathrm{PO}_{n}\left(\mathbb{F}_{q}\right)$, and the spinor norm agrees with the determinant on $\mu_{2}^{n}$. So $\mu_{2}^{n-1}$ is a subgroup of $\mathrm{PSO}_{n}^{+}\left(\mathbb{F}_{q}\right)$, and the rest goes as before.

Remark 37. Note that $\mathrm{SL}_{n}$ and $\mathrm{O}_{n}$ contain many pseudo-reflections, so the triviality of $C\left(\mathrm{SL}_{n}, \mathrm{Aut}^{\mathrm{u}}\left(\mathbb{A}^{n}\right)\right)$ and of $C\left(\mathrm{O}_{n}, \mathrm{Aut}^{\mathrm{u}}\left(\mathbb{A}^{n}\right)\right)$ also follows from (13).

However, $\mathrm{SO}^{+}$does not contain pseudo-reflections, so we do need Proposition 36 and Corollary 32 together to see that $C\left(\mathrm{SO}_{n}^{+}, \mathrm{Aut}^{\mathrm{u}}\left(\mathbb{A}^{n}\right)\right)$ is trivial.

To get another set of examples, let $T \subset \mathrm{GL}_{n}(\mathbb{C})$ be the diagonal subgroup and $N(T)$ its normalizer. Thus $N(T)=T \rtimes S_{n}$, where we realize $S_{n}$ as the group of permutation matrices. For $G \subset S_{n}$ and $m \in \mathbb{N}$, set $G_{m}:=\mu_{m}^{n} \rtimes G \subset N(T)$, and let $\bar{G}_{m}$ be the image of $G_{m}$ in $\mathrm{PGL}_{n}(\mathbb{C})$. We have a split extension

$$
1 \rightarrow \mu_{m}^{n-1} \rightarrow \bar{G}_{m} \rightarrow G \rightarrow 1
$$

Corollary 38. $\bar{G}_{m} \curvearrowright \mathbb{P}_{\mathbb{C}}^{n-1}$ is birationally irreducible if $m>1$ and $G \curvearrowright \mu_{p}^{n-1}$ is irreducible for some prime $p \mid m$.

Proof. As in the proof of Corollary 35 we obtain that the $\mu_{p}^{n-1}$-action on $Z$ is not faithful. By our assumptions, $\mu_{p}^{n-1} \subset \bar{G}_{p}$ is a minimal normal subgroup. Thus the $\mu_{p}^{n-1}$-action on $Z$ is trivial. This gives a faithful $\mu_{p}^{n-1}$-action on $\mathbb{P}_{K}^{r}$, which is impossible since $r<n-1$.

Remark 38. 1. $G \curvearrowright \mu_{p}^{n-1}$ is irreducible for $p \gg 1$ iff the $G$-action on the quotient $\mathbb{C}^{n} / \mathbb{C}(1, \ldots, 1)$ is irreducible.

For $n \geq 4$, the action $A_{n} \curvearrowright \mu_{p}^{n-1}$ is irreducible iff $p \nmid n$.
$\mathbb{Z} / n \curvearrowright \mu_{p}^{n-1}$ is irreducible iff $\left(x^{n}-1\right) /(x-1)$ is irreducible over $\mathbb{F}_{p}$. That is, $n$ is prime, $p \neq n$ and $n \nmid p-1$.

Remark 38.2. The corollary also holds in positive characteristic, as long as $p \neq \operatorname{char} k$.

Remark 38.3. The previous method shows that if $g: \mathbb{P}_{K}^{n-1} \rightarrow Z$ is any $\bar{G}_{m^{-}}$ equivariant morphism to a smooth variety of dimension $<n-1$, then $\mu_{p}^{n-1}$ acts faithfully on the fibers of $g$. We have fixed points in some fibers, but these may be singular fibers.

However, if $p \geq n$ and the generic fibers are separably rationally connected, then Hau19 guarantees fixed points in smooth fibers, leading to a contradiction as before.

If char $K=0$, we get that $\bar{G}_{p} \curvearrowright \mathbb{P}_{K}^{n-1}$ is not $\bar{G}_{p}$-birational to any nontrivial Mori fiber space.

Nonetheless, $\bar{G}_{p} \curvearrowright \mathbb{P}_{K}^{n-1}$ is most likely not birationally rigid. For $n=4$ this is proved in [CS19, 2.1].

The following definition of birational rigidity avoids the definition of Mori fiber spaces. It is equivalent to the usual definition, whenever resolution of singularities and the minimal model program are known to work. See Cor00 for a more general introduction.

Definition 39. [Birational rigidity] A group action $G \curvearrowright X$ on a smooth projective variety is birationally rigid if the following holds.

Let $G \curvearrowright Y$ be any action on a smooth projective variety $Y$, that is $G$-birationally equivalent to $G \curvearrowright X$. Then, whenever we run the $G$-equivariant minimal model program on $Y$, the end result $G \curvearrowright Y^{\mathrm{m}}$ is isomorphic to $G \curvearrowright X$. (See [KM98] for an introduction to the minimal model program.)

It is easy to see that if $G \curvearrowright \mathbb{P}_{k}^{n}$ is birationally reducible, then the end result of a $G$-equivariant minimal model program can be a (nontrivial) product $\mathbb{P}^{r} \times Z^{\prime}$. So birational rigidity implies birational irreducibility.

In [CS19, CS19], the $G$-birational non-rigidity is established by exhibiting one $G \curvearrowright Y^{\mathrm{m}}$ that is not isomorphic to $G \curvearrowright \mathbb{P}_{k}^{n}$. In most cases, this $Y^{\mathrm{m}}$ is not a product. However, in many cases the papers do not describe all possible $G \curvearrowright Y^{\mathrm{m}}$. So the birational (ir)reducibility of several of the non-rigid cases remains to be decided.

We already noted the birationally rigid examples from [Sak19, CS19]. Next we discuss an example in positive characteristic, that is reducible but birationally rigid.

Proposition 40. Let $P_{n}\left(\mathbb{F}_{q}\right) \subset \mathrm{PGL}_{n}\left(\mathbb{F}_{q}\right)$ be the parabolic subgroup that stabilizes the hyperplane $\left(x_{1}=0\right)$. The natural action $P_{n}\left(\mathbb{F}_{q}\right) \curvearrowright \mathbb{P}^{n-1}$ is birationally rigid (over $\overline{\mathbb{F}}_{q}$ ) if $q>n$.

Proof. Using [KSC04, 5.12], it is enough to prove that, for any $P_{n}\left(\mathbb{F}_{q}\right)$-invariant pencil of hypersurfaces $|H|$ (without fixed components), and every point $p \in \mathbb{P}^{n-1}$, we have mult ${ }_{p}|H|<(\operatorname{deg}|H|) / n$. (Note that the statement in [KSC04, 5.12] uses not the degree of $H$, but the degree of $H$ divided by the degree of the anticanonical class, which is $n$ for $\mathbb{P}^{n-1}$.)

We show in (40, 2) that, for every point $p \in \mathbb{P}^{n-1} \backslash\left(x_{1}=0\right)$ and every $P_{n}\left(\mathbb{F}_{q}\right)$ invariant hypersurfaces $H$, we have mult ${ }_{p} H<(\operatorname{deg} H) / q$.

If $p \in\left(x_{1}=0\right)$, then a general member $H \in|H|$ does not contain $\left(x_{1}=0\right)$, and, by induction on the dimension, $\operatorname{mult}_{p}|H| \leq \operatorname{mult}_{p}\left(\left.H\right|_{\left(x_{1}=0\right)}\right)<(\operatorname{deg}|H|) / q$, and we are done.

Claim 40. 1. For any polynomial $f \in \overline{\mathbb{F}}_{q}\left[x_{1}, \ldots, x_{n}\right]$

$$
\sum_{p \in \mathbb{F}_{q}^{n}} \operatorname{mult}_{p} f \leq q^{n-1} \operatorname{deg} f .
$$

Proof. The base points of the linear system $|M|=\left|\sum_{i} \lambda_{i}\left(x_{i}^{q}-x_{i}\right)\right|$ are exactly the points in $\mathbb{F}_{q}^{n}$. Thus

$$
\sum_{p \in \mathbb{F}_{q}^{n}} \operatorname{mult}_{p} f \leq\left((f=0) \cdot|M|^{n-1}\right)=q^{n-1} \operatorname{deg} f
$$

Claim 40. 2. Let $H \subset \mathbb{P}^{n-1}$ be a $P_{n}\left(\mathbb{F}_{q}\right)$-invariant hypersurface. Then $\operatorname{mult}_{p} H \leq$ $(\operatorname{deg} H) / q$ for every $p \in \mathbb{P}^{n-1} \backslash\left(x_{1}=0\right)$.

Proof. Writing $p=\left(c_{1}: \cdots: c_{n}\right)$, we may assume that $c_{1}=1$. Acting with the matrices in the unipotent radical of $P_{n}\left(\mathbb{F}_{q}\right)$, we get the points

$$
\left\{\left(1: c_{2}+a_{2}: \cdots: c_{n}+a_{n}\right): a_{i} \in \mathbb{F}_{q}\right\}
$$

If $H=(h=0)$, then

$$
q^{n-1} \operatorname{mult}_{p} H=\sum_{p \in \mathbb{F}_{q}^{n}} \operatorname{mult}_{p} h\left(1, x_{2}+c_{2}, \ldots, x_{n}+c_{n}\right) \leq q^{n-2} \operatorname{deg} H .
$$

Example 403. The bound $\operatorname{mult}_{p} H \leq(\operatorname{deg} H) / q$ is essentially optimal. If $H$ is the product of all linear forms over $\mathbb{F}_{q}$, then $\operatorname{deg} H=\left(q^{n-1}-1\right) /(q-1)$ and mult $_{p} H=\left(q^{n-2}-1\right) /(q-1)$.

Remarks 40.4. $P_{n}\left(\mathbb{F}_{q}\right)$ contains many pseudo-reflections, so it would be more interesting to get similar results for $\mathrm{SO}_{n}\left(\mathbb{F}_{q}\right)$ and $\mathrm{SU}_{n}\left(\mathbb{F}_{q}\right)$.

Also, most likely $P_{n}\left(\mathbb{F}_{q}\right) \curvearrowright \mathbb{P}^{n-1}$ is birationally rigid even if $q \leq n$, with finitely many exceptions

A straightforward generalization of the proof of Theorem 30 gives the following.
Theorem 41. Let $X$ be a smooth, projective variety and $G \subset \operatorname{Aut}(X)$ a geometrically reduced subgroup scheme, such that the $G$-equivariant Picard number of $X$ is 1 . Let $H \subset X$ be a $G$-irreducible divisor, and $\phi \in \operatorname{Aut}(X \backslash H)$ an automorphism that commutes with $G$. Then
(1) either $\phi$ extends to an automorphism of $X$,
(2) or there are $G$-equivariant rational maps

$$
\begin{equation*}
(G \curvearrowright H) \stackrel{\tau}{\sim}\left(G \curvearrowright\left(\mathbb{P}_{k}^{r} \times Z\right)\right) \xrightarrow{\pi}(G \curvearrowright Z) \xrightarrow{\sigma}(G \curvearrowright H), \tag{41,2.a}
\end{equation*}
$$

where $\tau$ is birational, $r \geq 1, \pi$ is the coordinate projection, and the $G$-action on $\mathbb{P}_{k}^{r} \times Z$ may be only rational.

## 5. LOW DIMENSIONS

We have a complete description of $\operatorname{Aut}\left(k[x, y]^{G}\right)$. AZ13] treats (42 1$)$ for $k=\mathbb{C}$, using an argument to recognize the linear embeddings $\mathbb{A}^{1} \hookrightarrow \mathbb{A}^{2}$. It is not clear how to generalize the method of AZ13 to higher dimensions.

Proposition 42. Let $k$ be a field and $G \subset \mathrm{GL}_{2}$ a finite, geometrically reduced subgroup scheme. Assume that char $k \nmid|G|$. Then we have one of the following alternatives.
(1) $G$ is not diagonalizable over $k$. Then $\mathbf{N}\left(G, \operatorname{Aut}\left(\mathbb{A}_{k}^{2}\right)\right)=\mathbf{N}\left(G, \mathrm{GL}_{2}\right)$ is an algebraic group. Its identity component is a $k$-torus of dimension 2 if $G$ is commutative, and the group of scalars $\mathbb{G}_{m}$ if $G$ is not commutative.
(2) $G$ is diagonalizable over $k$ with eigenbasis $(1,0),(0,1)$.
(a) If $G \cap\left(\mathbb{G}_{m} \times\{1\}\right)$ and $G \cap\left(\{1\} \times \mathbb{G}_{m}\right)$ are both nontrivial, then $N\left(G, \operatorname{Aut}\left(\mathbb{A}_{k}^{2}\right)\right)=\mathbb{G}_{m} \times \mathbb{G}_{m}$.
(b) Otherwise $N\left(G, \operatorname{Aut}\left(\mathbb{A}_{k}^{2}\right)\right)$ is infinite dimensional.

Proof. If $G$ is not diagonalizable over $k$, then the induced action on $\mathbb{P}_{k}^{1}$ is birationally irreducible by (34, 1). Thus $C\left(G\right.$, Aut $\left.^{\mathrm{u}}(k[V])\right)=\{1\}$ by Corollary 32, and we have (42,1).

We discussed the $n$-dimensional version of (42 2.a) in Example 13, Otherwise $G \cong \mu_{n}$ acting as $(x, y) \mapsto\left(\epsilon x, \epsilon^{q} y\right)$ for some $0 \leq q<n$. If $(q, n)=1$ then $G$ contains no pseudo-reflections, and $N\left(G\right.$, Aut $\left.^{\mathrm{u}}\left(\mathbb{A}_{k}^{2}\right)\right)$ contains the elementary automorphisms

$$
(x, y) \mapsto\left(c x, y+x^{q} g\left(x^{n}\right)\right) \quad \text { and } \quad(x, y) \mapsto\left(x+y^{q^{\prime}} g\left(y^{n}\right), c y\right)
$$

where $0<q^{\prime}<n$ is the inverse of $q$ modulo $n$. The arguments in AU22 should give that, together with the linear automorphisms, they generate the full automorphism group.

If $(q, n)>1$, then $G$ contains a pseudo-reflection, and $N\left(G\right.$, Aut $\left.^{\mathrm{u}}\left(\mathbb{A}_{k}^{2}\right)\right)$ consists of the automorphisms $(x, y) \mapsto\left(c x, y+x^{q} g\left(x^{n}\right)\right)$ by Example 13 ,

Next we consider irreducible subgroups $G \subset \mathrm{GL}_{3}$. The main work is done in Sak19, which in turn relies on the classification of finite subgroups of $\mathrm{GL}_{3}(\mathbb{C})$, due to Bli17. (For lists in positive characteristic, see [FO05.)

Proposition 43. Let $G \subset \mathrm{GL}_{3}(\mathbb{C})$ be an irreducible subgroup. Then $N\left(G, \operatorname{Aut}\left(\mathbb{C}^{3}\right)\right)=$ $N\left(G, \mathrm{GL}_{3}(\mathbb{C})\right)$.

Proof. By Sak19] $G \subset \mathrm{GL}_{3}(\mathbb{C})$ is birationally rigid iff it is irreducible, and $G$ is not a central extension of $A_{4}$ or $S_{4}$. Since birationally rigid implies birationally irreducible, it remains to deal with the unique irreducible $A_{4}$ and $S_{4}$ actions. (These are obtained as the permutation representation on $\mathbb{C}^{4}$ restricted to the hyperplane $\left.\sum x_{i}=0.\right)$

The orbits are described in [Sak19, 3.14], and [Sak19, 2.1] summarizes the possible links, due to Cor95.

The length 3 orbit gives the quadratic Cremona transformation. Blowing up the points in a length 6 orbit gives a cubic surface, the other side of the link contracts the 6 conics that pass through 5 of the 6 points; we are back to $\mathbb{P}^{2}$. Finally, blowing up the points in a length 4 orbit, we get a conic bundle $B_{4} \mathbb{P}^{2} \rightarrow C \cong \mathbb{P}^{1}$ with 3 singular fibers, where the 6 curves in the 3 singular fibers form a single $A_{4}$-orbit.

We can now do a sequence of Type II links that preserve the conic bundle structure and the 3 singular fibers. The only other possibility is a Type I link that takes us back to $\mathbb{P}^{2}$. Thus the only possibility for (412.a) is

$$
\begin{equation*}
\left(A_{4} \curvearrowright \mathbb{P}^{2}\right) \stackrel{\tau}{\sim}\left(A_{4} \curvearrowright B_{4} \mathbb{P}^{2}\right) \xrightarrow[\rightarrow]{\pi}\left(A_{4} \curvearrowright C\right) \xrightarrow{\sigma}\left(A_{4} \curvearrowright \mathbb{P}^{2}\right) \tag{43,1}
\end{equation*}
$$

Note, however, that the $A_{4}$-action on $C$ reduces to a $\mathbb{Z} / 3$-action. This is clear if we write the 4 points as $( \pm 1: 0: 1),(0: \pm 1: 1)$. Then $B_{4} \mathbb{P}^{2} \rightarrow C \cong \mathbb{P}^{1}$ is given by the pencil $\lambda\left(x^{2}+y^{2}-z^{2}\right)+\mu x y$. Every member is invariant under $(x: y: z) \mapsto(-x:-y: z)$ and $(x: y: z) \mapsto(y: x: z)$.

However, the action of $(\mathbb{Z} / 2)^{2} \subset A_{4}$ on $\mathbb{P}^{2}$ is trivial only at 3 points, so $\sigma$ in (43) 1) can not exist. The same argument applies for $S_{4}$.

Over a number field, we give a 3 -dimensional, irreducible example.
Example 44. Let $p=1+3 m$ be a prime and set $\epsilon:=e^{2 \pi i / p}$. The Galois group of $\mathbb{Q}(\epsilon) / \mathbb{Q}$ is $\mathbb{Z} /(3 m)$. Choose $c \neq 1$ such that $c^{3} \equiv 1 \bmod p$. Let $\sigma_{i}$ be the elementary symmetric polynomials in $\epsilon, \epsilon^{c}, \epsilon^{c^{2}}$ (so $\sigma_{3}=1$ ). They generate a subfield $K_{p} \subset \mathbb{Q}(\epsilon)$ such that $\operatorname{deg} \mathbb{Q}(\epsilon) / K_{p}=3$, and $\epsilon, \epsilon^{c}, \epsilon^{c^{2}}$ satisfy the equation

$$
g_{p}(x):=x^{3}-\sigma_{1} x^{2}+\sigma_{2} x-\sigma_{3}=0
$$

Consider the matrix

$$
M_{p}:=\left(\begin{array}{ccc}
0 & 0 & \sigma_{3} \\
1 & 0 & -\sigma_{2} \\
0 & 1 & \sigma_{1}
\end{array}\right) .
$$

Its characteristic polynomial is $g_{p}(x)$, hence its eigenvalues are $\epsilon, \epsilon^{c}, \epsilon^{c^{2}} . M_{p}$ defines an irreducible linear representation $\mathbb{Z} / p \hookrightarrow \mathrm{GL}_{3}\left(K_{p}\right)$. We claim that the induced $M_{p}: \mathbb{Z} / p \curvearrowright \mathbb{P}_{K_{p}}^{2}$ are birationaly irreducible, but not birationaly rigid.

The 3 eigenvectors of $M_{p}$ give a point of degree 3 on $\mathbb{P}_{K_{p}}^{2}$, the other $\mathbb{Z} / p$-orbits of points have degree divisible by $p$.

Arguing as in Sak19] (or as in Proposition 43), the degree 3 point gives the quadratic Cremona transformation. This corresponds to the complex conjugate $\bar{M}_{p}$, whose eigenvalues are the inverses of the eigenvalues of $M_{p}$. The two actions on $\mathbb{P}_{K_{p}}^{2}$ are not isomorphic. The only other possibility is for $p=7$, where degree 7 points give Bertini involutions.

For $p=7$ we have $K_{p}=\mathbb{Q}(\sqrt{-7})$ and

$$
g_{3}(x)=x^{3}-\alpha x^{2}-(1+\alpha) x-1, \quad \text { where } \quad \alpha:=\epsilon+\epsilon^{2}+\epsilon^{4}=\frac{-1+\sqrt{-7}}{2}
$$

The following is a 4 -dimensional imprimitive example.
Example 45. Let $2 \mathrm{I} \times 2 \mathrm{I} \subset \mathrm{GL}_{4}(\mathbb{C})$ be the block-diagonal subgroup and $\rho$ the involution interchanging the 2 blocks: $\rho\left(x_{1}: x_{2}: y_{1}: y_{2}\right)=\left(y_{1}: y_{2}: x_{1}: x_{2}\right)$. Together they generate $G \subset \mathrm{GL}_{4}(\mathbb{C})$ of order $2 \cdot 120^{2}$. The commutator subgroup of $G$ is $2 \mathrm{I} \times 2 \mathrm{I}$, whose center is $\mu_{2} \times \mu_{2}$.

The quotient by $2 \mathrm{I} \times 2 \mathrm{I}$ is the product

$$
\mathbb{C}^{4} /(2 \mathrm{I} \times 2 \mathrm{I}) \cong\left(\mathrm{u}_{1}^{2}+\mathrm{u}_{2}^{3}+\mathrm{u}_{3}^{5}=0\right) \times\left(\mathrm{v}_{1}^{2}+\mathrm{v}_{2}^{3}+\mathrm{v}_{3}^{5}=0\right)
$$

and then we take the quotient by $\bar{\rho}:\left(u_{1}, u_{2}, u_{3}\right) \leftrightarrow\left(v_{1}, v_{2}, v_{3}\right)$.
$G$ is irreducible but imprimitive, so it is birationally reducible by (33,2). Nonetheless, we claim that

$$
\begin{equation*}
\operatorname{Aut}\left(k\left[x_{1}, x_{2}, y_{1}, y_{2}\right]^{G}\right)=\left(\mathbf{N}\left(G, \mathrm{GL}_{4}\right) / G\right)(k) \cong k^{\times} \tag{45,1}
\end{equation*}
$$

To see this, note that the induced action on $\mathbb{P}^{3}$ is faithful on $\bar{G}:=G /\left(\right.$ diagonal $\left.\mu_{2}\right)$. The center of $\bar{G}$ is the involution $\chi:\left(x_{1}: x_{2}: y_{1}: y_{2}\right) \mapsto\left(-x_{1}:-x_{2}: y_{1}: y_{2}\right)$.

The key observation is that while $\bar{G} /(\chi)=G /\left(\mu_{2} \times \mu_{2}\right)$ does act faithfully on $\mathbb{P}^{1} \times \mathbb{P}^{1}, \bar{G}$ can not act faithfully on a rational surface DI09]. Thus if we have

$$
\left(\bar{G} \curvearrowright \mathbb{P}^{3}\right) \stackrel{\tau}{\sim}\left(\bar{G} \curvearrowright\left(\mathbb{P}^{r} \times Z\right)\right) \xrightarrow{\pi}(\bar{G} \curvearrowright Z) \xrightarrow{\sigma}\left(\bar{G} \curvearrowright \mathbb{P}^{3}\right)
$$

as in (302.a), then $\chi$ acts trivially on $Z$, hence also on $\sigma(Z) \subset \mathbb{P}^{3}$. However, the fixed locus of $\chi$ on $\mathbb{P}^{3}$ is the union of 2 disjoint lines that are interchanged by $\rho$. Thus there is no $\rho$-equivariant map from $\mathbb{P}^{3}$ to the fixed locus of $\chi$.

By Theorem 30 we get the first equality in (45,1). Automorphisms of $G$ fix the commutator subgroup $2 \mathrm{I} \times 2 \mathrm{I}$, thus they are all inner. So $\mathbf{N}\left(G, \mathrm{GL}_{4}\right) / G=$ $\mathbf{C}\left(G, \mathrm{GL}_{4}\right) / G=\mathbb{G}_{m} /\left(\right.$ diagonal $\left.\mu_{2}\right)$.

It is possible that the automorphism group of $\mathbb{C}^{4} /(2 \mathrm{I} \times 2 \mathrm{I})$ is the obvious $\left(k^{\times}\right)^{2} \rtimes$ $\mathbb{Z} / 2$, but the above methods do not show this.

The same argument should apply to several other imprimitive $G \subset \mathrm{GL}_{4}(\mathbb{C})$ with 2 blocks, but one needs to exclude accidental actions on rational surfaces using the lists of DI09.

## 6. Fixed points and Rational maps

The following lemmas were used in the proofs of Propositions 3538
Lemma 46. [KS00, A.2] Let $A$ be an abelian group and $g: X \rightarrow Z$ an $A-$ equivariant rational map of proper $k$-varieties. If $A$ has a smooth (closed) fixed point on $X$, then it also has a (closed) fixed point on $Z$.
Lemma 47. Let $A$ be an abelian group acting faithfully on a $k$-variety $Z$ with $a$ smooth (closed) fixed point. Assume that char $k \nmid|A|$. Then $A$ can be generated by $\operatorname{dim} Z$ elements.

Proof. We may assume that $k$ is separably closed. The $A$-action on the tangent space at the fixed point is also faithful and diagonalizable.

While [KS00, A.2] guarantees a fixed point even if $Z$ is singular, Lemma 47 needs the fixed point to be smooth. This is usually not a problem if $A$-equivariant resolution of singularities holds for $Z$. When resolution is not known, the following variant is useful.

Lemma 48. Let $k$ be a field, $A:=\mu_{\ell}^{n}$ for some prime $\ell \neq \operatorname{char} k$, and $g: X \rightarrow Z$ an A-equivariant rational map of $k$-varieties. Assume that $A \curvearrowright X$ has a smooth, isolated, fixed point, and $\operatorname{dim} Z<n$. Then $A \curvearrowright Z$ is not faithful.

Proof. We may assume that $k$ is separably closed. Let $x \in X$ be a smooth, isolated fixed point. Choosing an $A$-eigenbasis of $m_{x} / m_{x}^{2}$, and $A$-equivariantly lifting it, we get local coordinates $\left(h_{1}, \ldots, h_{n}\right)$ at $x$ such that $A$ acts on them as

$$
\left(\epsilon_{1}, \ldots, \epsilon_{n}\right) \times\left(h_{1}, \ldots, h_{n}\right) \mapsto\left(\epsilon_{1} h_{1}, \ldots, \epsilon_{n} h_{n}\right)
$$

We use induction on $n$; the claim is clear if $n=1$.
We may assume that $Z$ is normal and projective. Set $X_{1}:=\left(h_{1}=0\right)$ and let $A \supset A_{1} \cong \mu_{\ell}^{n-1}$ be the kernel of the $A$-action on $h_{1}$. Then $g$ restricts to an $A$ equivariant rational map $g_{1}: X_{1} \rightarrow Z$. If $g_{1}$ is dominant, then $A \curvearrowright Z$ is not faithful since $A \curvearrowright X_{1}$ is not faithful.

If $g_{1}$ is not dominant, then, by Kol13, 2.22], after some blow-ups we may assume that the closure of $g_{1}\left(X_{1}\right)$ is a divisor, call it $Z_{1} \subset Z$.

If $\operatorname{dim} Z<n$, then $\operatorname{dim} Z_{1}<n-1$, hence $A_{1} \curvearrowright Z_{1}$ is not faithful by induction. Thus the kernel $K_{1}$ of $A \curvearrowright Z_{1}$ is $\mu_{\ell}^{r}$ for some $r \geq 2$.

The kernel acts on $\mathcal{O}_{Z}\left(-Z_{1}\right) / \mathcal{O}_{Z}\left(-2 Z_{1}\right)$ by a character $K_{1} \rightarrow k^{\times}$. Thus there is a $\mu_{\ell} \cong K_{2} \subset K_{1}$ that acts trivially on $\mathcal{O}_{Z} / \mathcal{O}_{Z}\left(-2 Z_{1}\right)$. Then $K_{2}$ acts trivially on $Z$.

Remark 49. The above lemmas use only the (non)existence of fixed points. The theory of the equivariant Burnside group developed in HKT20, KT21, HT22 looks at much finer properties, involving the fixed point sets and the representations on their normal bundles. It gives a powerful method to distinguish $G$-actions modulo $G$-birational equivalence. It would be interesting to see what it says about birational irreducibility.

## 7. Twisted forms of quotient singularities

The arguments to show Corollary 5 are pretty standard. The Galois cohomology part goes as expected following [Ser97, §.III.1], and so is computing automorphisms using the universal cover. For example, it was used in AZ13 for the same purposes.

50 (Proof of Corollary (5). For any $k$-scheme $Y$, its twisted forms are classified by $H^{1}\left(\operatorname{Gal}(\bar{k} / k), \operatorname{Aut}\left(Y_{\bar{k}}\right)\right)$; see $[\operatorname{Ser} 97, \S . I I I .1]$. Thus we need to understand $\operatorname{Aut}\left(\bar{k}[[\mathbf{x}]]^{G}\right)$, which is given by the sequence (11)

$$
1 \rightarrow C\left(G, \operatorname{Aut}^{\mathrm{u}}(\bar{k}[[\mathbf{x}]])\right) \rightarrow \operatorname{Aut}\left(\bar{k}[[\mathbf{x}]]^{G}\right) \rightarrow\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(\bar{k}) \rightarrow 1
$$

On the right hand side we have

$$
\left(\mathbf{N}\left(G, \mathrm{GL}_{n}\right) / G\right)(\bar{k})=N\left(G, \mathrm{GL}_{n}(\bar{k})\right) / G(\bar{k})
$$

which is exactly the group of graded auomorphisms of $k[\mathbf{x}]^{G}$. This gives the natural map (5) 1 ) $\rightarrow$ (5, 2).

For the converse we need to show that

$$
H^{1}\left(\operatorname{Gal}(\bar{k} / k), C\left(G, \operatorname{Aut}^{\mathrm{u}}(k[[\mathbf{x}]])\right)\right)=\{1\}
$$

Over a perfect field $k$, a unipotent group has a decreasing filtration whose subquotients are isomorphic to $\mathbb{G}_{a}$, and $H^{1}\left(\operatorname{Gal}(\bar{k} / k), \mathbb{G}_{a}\right)=0$ by [Ser97, §.II.1.1]. Thus $H^{1}(\operatorname{Gal}(\bar{k} / k), U)$ of any unipotent group $U$ is trivial by [Ser97, §.I.5.4].

Example 51. We give 2 examples when there are no twisted forms.
(51]1) Assume that $G \subset \mathrm{GL}_{n}(\bar{k})$ acts irreducibly, and every automorphism of $G$ is inner. Then $N\left(G, \mathrm{GL}_{n}(\bar{k})\right)=G \cdot \mathbb{G}_{m}(\bar{k})$, where $\mathbb{G}_{m}(\bar{k})$ is the group of scalars. Thus $N\left(G, \mathrm{GL}_{n}(\bar{k})\right) / G$ is the quotient of $\mathbb{G}_{m}$ by the center of $G$, hence isomorphic to $\mathbb{G}_{m}$. Thus

$$
H^{1}\left(\operatorname{Gal}(\bar{k} / k), N\left(G, \mathrm{GL}_{n}(\bar{k})\right)\right)=H^{1}\left(\operatorname{Gal}(\bar{k} / k), \mathbb{G}_{m}\right)=1
$$

and $k[[\mathbf{x}]]^{G}$ has no twisted forms.
(51)2) Assume that $G$ is simple, every automorphism of $G$ is inner, and char $k=$ 0 . Any representation of $G$ decomposes as $V=\oplus_{i}\left(V_{i} \otimes_{\bar{k}} \bar{k}^{m_{i}}\right)$ where the $V_{i}$ are distinct, irreducible representations. Then $N\left(G, \mathrm{GL}_{n}(\bar{k})\right) \cong \times_{i} \mathrm{GL}_{m_{i}}(\bar{k})$. Thus $H^{1}\left(\operatorname{Gal}(\bar{k} / k), N\left(G, \operatorname{GL}_{n}(\bar{k})\right)\right)=\times_{i} H^{1}\left(\operatorname{Gal}(\bar{k} / k), \mathrm{GL}_{m_{i}}(\bar{k})\right)=1$ by [Ser97, §.III.1.1]. Therefore $k[[\mathbf{x}]]^{G}$ has no twisted forms for all representations of $G$.

The following is closely related to BV22, 6.18].
Example 52. Let $G \subset \mathrm{GL}_{n}$ be a subgroup and assume that every automorphism of $G$ is inner. Then $C\left(G, \mathrm{GL}_{n}(\bar{k})\right)$, the centralizer of $G$ in $\mathrm{GL}_{n}$, surjects onto $N\left(G, \mathrm{GL}_{n}(\bar{k})\right)$. If, in addition, the center of $G$ is trivial, then $C\left(G, \mathrm{GL}_{n}(\bar{k})\right) \rightarrow$ $N\left(G, \mathrm{GL}_{n}(\bar{k})\right) / G(\bar{k})$ is an isomorphism. Thus we have a natural map

$$
\begin{aligned}
& H^{1}\left(\operatorname{Gal}(\bar{k} / k), N\left(G, \mathrm{GL}_{n}(\bar{k})\right) / G(\bar{k})\right) \cong H^{1}\left(\operatorname{Gal}(\bar{k} / k), C\left(G, \mathrm{GL}_{n}(\bar{k})\right)\right) \rightarrow \\
& \quad \rightarrow H^{1}\left(\operatorname{Gal}(\bar{k} / k), \mathrm{GL}_{n}(\bar{k})\right)=1
\end{aligned}
$$

We conclude that every twist of $k[[\mathbf{x}]]^{G}$ is of the form $k[[\mathbf{x}]]^{G^{\prime}}$, where $G^{\prime} \subset \mathrm{GL}_{n}$ is a twisted form of $G$. (More generally, the above argument applies whenever $N\left(G, \mathrm{GL}_{n}(\bar{k})\right) \rightarrow N\left(G, \mathrm{GL}_{n}(\bar{k})\right) / G$ has a canonical splitting.)

Applying the Nishimura lemma to $\hat{\mathbb{A}}^{n} \rightarrow \operatorname{Spec}_{k} R^{G^{\prime}}$ we get that every resolution of every twist of $k[[\mathbf{x}]]^{G}$ has a $k$-point over the origin. Thus Spec $k[[\mathbf{x}]]^{G}$ is an $R$-singularity in the terminology of [BV22, 6.11].

See [KSC04, p.183] for an elegant proof of the Nishimura lemma due to E. Szabó.
Remark 53. For surface singularities, $N\left(G, \mathrm{GL}_{2}(\bar{k})\right)$ acts on the dual graph of the minimal resolution, and, except for the $\mathbb{A}^{2} / \frac{1}{n}(1,1)$ quotients, the kernel is a torus. Since $H^{1}\left(\operatorname{Gal}(\bar{k} / k), \mathbb{G}_{m}\right)=0$ by Ser97, §.II.1.1], the twisted forms are determined by the symmetries of the dual graph, except when the dual graph consists of a single curve.

There is no minimal resolution in higher dimensions, and it is not clear whether there is a similarly clear geometric description.

## 8. Uniqueness of cones

We end with a discussion of general cones.
Definition 54. Let $k$ be a field, $X$ a normal, projective $k$-variety and $\Delta$ an ample $\mathbb{Q}$-divisor on $X$. The cone over $(X, \Delta)$ is

$$
R(X, \Delta):=\oplus_{m \geq 0} H^{0}\left(X, \mathcal{O}_{X}(\lfloor m \Delta\rfloor)\right), \quad \text { or } \quad C_{a}(X, \Delta):=\operatorname{Spec}_{k} R(X, \Delta)
$$

The completions are denoted by $\hat{R}(X, \Delta)$ and $\hat{C}_{a}(X, \Delta)$.
Both $R(X, \Delta)$ and $\hat{R}(X, \Delta)$ come with a positive grading, where $\operatorname{deg} r=m$ iff $r \in H^{0}\left(X, \mathcal{O}_{X}(\lfloor m \Delta\rfloor)\right)$. A positive grading is equivalent to a postive $\mathbb{G}_{m}$-action defined on the homogeneous elements by $(\lambda, r) \mapsto \lambda^{\operatorname{deg} r} r$.

Set $L:=\mathcal{O}_{X}(\lfloor\Delta\rfloor)$ and let $\{\Delta\}:=\Delta-\lfloor\Delta\rfloor$ be the fractional part of $\Delta$. Then

$$
\begin{equation*}
R(X, \Delta) \cong \oplus_{m \geq 0} H^{0}\left(X, L^{[m]}(\lfloor m\{\Delta\rfloor\})\right) \tag{54,2}
\end{equation*}
$$

thus the cone is determined by $\left(X, \mathcal{O}_{X}(\lfloor\Delta\rfloor),\{\Delta\}\right)$.
Conversely, an observation going back at least to Dol75, Pin77 is the following.
Lemma 55. Let $(R, m, \mathrm{deg})$ be a normal, complete, local $k$-algebra with a positive grading such that $R / m$ is finite over $k$. Then ( $R, m, \mathrm{deg}$ ) is a completed cone over a unique $\left(X, \mathcal{O}_{X}(\lfloor\Delta\rfloor),\{\Delta\}\right)$.

Sketch of proof. $R$ is the completion of $\oplus_{m \geq 0} R_{m}$ where $R_{m} \subset R$ is the set of degree $m$ homogeneous elements. Set $X:=\operatorname{Spec} \oplus_{m \geq 0} R_{m}$. Then $R_{m}=$ $H^{0}\left(X, \mathcal{O}_{X}(m)\right)$ and $R$ is the completion of $\oplus_{m \geq m} H^{0}\left(X, \mathcal{O}_{X}(m)\right)$.

If we work with $\hat{R}(X, \Delta)$, then this way we recover $\lfloor\Delta\rfloor \sim \mathcal{O}_{X}(1)$. Finally we get $m\{\Delta\}$ as the divisor associated to coker $\left[\mathcal{O}_{X}(1)^{\otimes m} \rightarrow \mathcal{O}_{X}(m)\right]$ for $m$ sufficiently divisible.

Next we consider when $\hat{R}(X, \Delta)$ admits a unique positive grading. Background results on algebraic group actions on complete local rings, and the definition of the maximal reductive quotient $\mathbf{A u t}_{k}^{\text {red }}(\hat{R}(X, \Delta))$ are discussed in (57). (Note that Aut $_{k}^{\text {red }}(\hat{R}(X, \Delta))$ denotes an algebraic group whose $k$-points are $\operatorname{Aut}_{k}^{\text {red }}(\hat{R}(X, \Delta))$. The difference becomes important for us only when $k$ is finite.)

Proposition 56. Let $k$ be a perfect field, $X$ a normal, projective $k$-variety and $\Delta$ an ample $\mathbb{Q}$-divisor on $X$. The following are equivalent.
(1) $\hat{R}(X, \Delta)$ uniquely determines the triple $\left(X, \mathcal{O}_{X}(\lfloor\Delta\rfloor),\{\Delta\}\right)$.
(2) There is no faithful $\mathbb{G}_{m}^{2}$-action on $\hat{R}(X, \Delta)$.
(3) Aut $_{k}^{\text {red }}(\hat{R}(X, \Delta))$ is a finite group extended by $\mathbb{G}_{m}$.
(4) There is no faithful $\mathbb{G}_{m}$-action on $\left(X, \mathcal{O}_{X}(\lfloor\Delta\rfloor),\{\Delta\}\right)$.

Proof. Let $\chi_{i}: \mathbb{G}_{m} \rightarrow \operatorname{Aut}_{k}(\hat{R}(X, \Delta))$ be 2 commuting $\mathbb{G}_{m}$-actions such that $\chi_{1}$ is positive. Then $\chi_{2} \chi_{1}^{r}$ is positive for all $r \gg 1$, giving infinitely many different positive gradings on $\hat{R}(X, \Delta)$. This shows that (1) $\Rightarrow(2)$.

If (2) holds then the maximal split torus $T$ of $\mathbf{A u t}_{k}^{\text {red }}(\hat{R}(X, \Delta))$ has dimension 1. Then the identity component of $\mathbf{A} \mathbf{u t}{ }_{k}^{\text {red }}(\hat{R}(X, \Delta))$ is either $T$ or $\mathrm{SL}_{2}$. However, it can not be $\mathrm{SL}_{2}$ since in every representation of $\mathrm{SL}_{2}$ its torus acts with both positive and negative weights. This proves $(2) \Rightarrow(3)$, and $(3) \Rightarrow(1)$ follows from Lemma 55.

If there is a faithful $\mathbb{G}_{m}$-action on $\left(X, \mathcal{O}_{X}(\lfloor\Delta\rfloor),\{\Delta\}\right)$, then we get a faithful $\mathbb{G}_{m}^{2}$-action on $\hat{R}(X, \Delta)$, and conversely. Thus (2) $\Leftrightarrow(4)$.
57. Let $(A, m)$ be a complete local $k$-algebra such that $A / m$ is finite over $k$. Then each $\operatorname{Aut}_{k}\left(A / m^{r}\right)$ is an algebraic group and we have natural homomorphisms

$$
q_{r}^{r+s}: \boldsymbol{A u t}_{k}\left(A / m^{r+s}\right) \rightarrow \operatorname{Aut}_{k}\left(A / m^{r}\right)
$$

with unipotent kernels for $r \geq 2$. For fixed $r$, the images of $q_{r}^{r+s}$ stabilize for $s \gg 1$, let us denote this subgroup by

$$
\operatorname{Aut}_{k}^{\ell}\left(A / m^{r}\right) \subset \boldsymbol{A u t}_{k}\left(A / m^{r}\right)
$$

We identify the automorphism scheme $\boldsymbol{\operatorname { A u t }}(A, m)$ with the inverse limit diagram

$$
\cdots \rightarrow \operatorname{Aut}_{k}^{\ell}\left(A / m^{r+1}\right) \rightarrow \operatorname{Aut}_{k}^{\ell}\left(A / m^{r}\right) \rightarrow \cdots
$$

Warning. Note that $\operatorname{Aut}(A, m)$ is the inverse limit of the $k$-points

$$
\begin{equation*}
\cdots \rightarrow \operatorname{Aut}_{k}^{\ell}\left(A / m^{r+1}\right) \rightarrow \operatorname{Aut}_{k}^{\ell}\left(A / m^{r}\right) \rightarrow \cdots \tag{57,2}
\end{equation*}
$$

but we do not discuss the possible scheme structure of $\boldsymbol{A u t}_{k}(A, m)$ here.
By a finite dimensional subgroup scheme of $\operatorname{Aut}_{k}(A, m)$ we mean a sequence of subgroup schemes $G_{r} \subset \operatorname{Aut}_{k}^{\ell}\left(A / m^{r}\right)$ such that the induced $q_{r}^{r+s}: G_{r+s} \rightarrow G_{r}$ are surjective and isomorphisms for $r \gg 1$. Similar definition applies to quotients.

Let $U_{r}^{\ell} \subset \operatorname{Aut}_{k}^{\ell}\left(A / m^{r}\right)$ denote the unipotent radical and $R_{r}^{\ell}:=\operatorname{Aut}_{k}^{\ell}\left(A / m^{r}\right) / U_{r}^{\ell}$ the maximal reductive quotient. Since the kernel of $q_{r}^{r+s}$ is unipotent, the induced maps $R_{r+1}^{\ell} \rightarrow R_{r}^{\ell}$ are isomorphisms for $r \geq 2$. This defines $\mathbf{A u t}_{k}^{\text {red }}(A, m):=R_{r}^{\ell}$ (for any $r \geq 2$ ) as the maximal reductive quotient of $\mathbf{A u t}_{k}(A, m)$.

If the characteristic is 0 , then the Levi subgroup realizes $\mathbf{A u t}_{k}^{\text {red }}(A, m)$ as a subgroup of $\mathbf{A u t}_{k}(A, m)$, unique up to conjugation. Thus the splitting of (20, 1) is automatic. (In positive characteristic there are no Levi subgroups in general.)

If $k$ is perfect then a Borel subgroup of $\boldsymbol{A u t}_{k}^{\ell}\left(A / m^{r+1}\right)$ maps onto a Borel subgroup of $\boldsymbol{A u t}_{k}^{\ell}\left(A / m^{r}\right)$, and the dimension of their maximal split subtori is the same for $r \geq 2$ [Bor91, 20.9]. Taking the limit we get maximal split subtori $T \subset \mathbf{A u t}_{k}(A, m)$. They are conjugate to each other and map isomorphically to the maximal split subtori of $\mathbf{A u t}_{k}^{\text {red }}(A, m)$.

Remark 58. If there is a $\mathbb{G}_{m}^{r}$-action on $\left(X, \mathcal{O}_{X}(\lfloor\Delta\rfloor),\{\Delta\}\right)$, then the above argument shows that we get a $\mathbb{G}_{m}^{r+1}$-action on $\hat{R}(X, \Delta)$, and all other cone structures on $\hat{R}(X, \Delta)$ are obtained by quotienting by some $\mathbb{G}_{m} \hookrightarrow \mathbb{G}_{m}^{r+1}$.

If $X$ is smooth and not uniruled, then $X$ gives the unique non-uniruled exceptional divisor over the vertex of $\hat{R}(X, \Delta)$, cf. Kol96, VI.1.2]. Thus Proposition 56 is the expected result for such cones.

By contrast, if $X$ is Fano and klt, there can be many proper, birational morphisms $\pi: Y \rightarrow \hat{R}(X, \Delta)$ such that the exceptional set $E$ is a klt, Fano variety with negative normal bundle; see [Xu14, Kol21]. Then $E$ determines a filtration whose corresponding graded ring is a cone over $E$, so it looks like $\hat{R}(X, \Delta)$ could be isomorphic to a cone over $E$.

Nonetheless, Proposition 56 says that if $\boldsymbol{A u t}^{\circ}(X, \Delta)$ is unipotent, then these other filtrations do not come from a grading.
