# Real zeros of mixed random fewnomial systems 

Peter Bürgisser<br>Institute of Mathematics, Technische Universität Berlin<br>Berlin, Germany<br>pbuerg@math.tu-berlin.de

#### Abstract

Consider a system $f_{1}(x)=0, \ldots, f_{n}(x)=0$ of $n$ random real polynomials in $n$ variables, where each $f_{i}$ has a prescribed set of exponent vectors in a set $A_{i} \subseteq \mathbb{Z}^{n}$ of cardinality $t_{i}$, whose convex hull is denoted $P_{i}$. Assuming that the coefficients of the $f_{i}$ are independent standard Gaussian, we prove that the expected number of zeros of the random system in the positive orthant is at most $(2 \pi)^{-\frac{n}{2}} V_{0}\left(t_{1}-1\right) \ldots\left(t_{n}-1\right)$. Here $V_{0}$ denotes the number of vertices of the Minkowski sum $P_{1}+\ldots+P_{n}$. However, this bound does not improve over the bound in [8] for the unmixed case, where all supports $A_{i}$ are equal. All arguments equally work for real exponent vectors.

CCS Concepts: • Theory of computation $\rightarrow$ Computational geometry; • Mathematics of computing $\rightarrow$ Integral calculus.

Keywords: fewnomials, random polynomials, real algebraic geometry, sparsity

## 1 Introduction

In many applications, we want to understand or find the positive real solutions of a system of multivariate polynomial equations, e.g., see [11, 18, 38]. Bezout's theorem, which bounds the number complex zeros in terms of degrees, usually highly overestimates the number of real zeros. This can be already seen from Descartes' rule of signs [10, p. 42], which implies that a real univariate polynomial with $t$ terms

[^0]has at most $t-1$ positive zeros. In 1980, Khovanskii [22] obtained a far reaching generalization of Descartes' rule. He showed that the number of nondegenerate ${ }^{1}$ positive solutions of a system $f_{1}(x)=0, \ldots, f_{n}(x)=0$ of $n$ real polynomial equations in $n$ variables is bounded only in terms of $n$ and the number $t$ of distinct exponent vectors occurring in the system. This result in fact allows for any real exponents. Following Kushnirenko, one speaks of fewnomial systems, with the idea that the number $t$ of terms is small, see [23].

Understanding the complex zeros of fewnomial systems is much simpler: the famous BKK-Theorem [2, 27] states that for given finite supports $A_{1}, \ldots, A_{n} \subseteq \mathbb{Z}^{n}$ and Laurent polynomials $f_{i}(x)=\sum_{a \in A} c_{i}(a) x_{1}^{a_{1}} \cdots x_{n}^{a_{n}}$ with generic complex coefficients $c_{i}(a)$, the number of complex solutions in $\left(\mathbb{C}^{\times}\right)^{n}$ of a corresponding system $f_{1}(x)=0, \ldots, f_{n}(x)=0$ is given by $n!$ times the mixed volume of the Newton polytopes $P_{1}, \ldots, P_{n}$, where $P_{i}$ is defined as the convex hull of $A_{i}$.

Note that the number of real zeros has little to do with the metric properties of $P_{i}$ : indeed, replacing $A_{i}$ by a nonzero multiple $m_{i} A_{i}$ amounts to substituting $x_{i}$ by $x_{i}^{m_{i}}$. Clearly, this does not change the number of positive real zeros of a fewnomial system, however $P_{i}$ has been replaced by $m_{i} P_{i}$.

The bound on the number of real zeros obtained by Khovanskii is exponential in the number $t$. It is widely conjectured that this bound is far from optimal: in fact it is conjectured [32] that for fixed $n$, the number of nondegenerate positive solutions of a fewnomial system with $t$ exponent vectors is bounded by a polynomial in $t$. Quite surprisingly, this question is open even for $n=2$ ! For results in special cases, we refer to $[1,3,4,25,26,38]$. Moreover, there is a very interesting connection to complexity theory [5, 24].

Given this state of affairs of real fewnomial theory, a possible way to advance is to ask what happens in generic situations. This can be made formal by considering random real fewnomial systems, see [8, 12, 28, 29, 33, 37]. Fix supports $A_{1}, \ldots, A_{n} \subseteq \mathbb{Z}^{n}$ of cardinality $t_{1}, \ldots, t_{n}$, respectively, and consider a system of $n$ random polynomials $f_{i}(x)$ as above, but now the coefficients $c_{i}(a)$ are assumed to be independent standard Gaussian. Let us denote by $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)$ the expectation of the number of nondegenerate positive real zeros of such system. Actually, we work in more generality, allowing any subsets $A_{i}$ of $\mathbb{R}^{n}$; see Section 4.

In [8] it was proven that $\mathbb{E}(A, \ldots, A) \leq 2^{1-n}\binom{t}{n}$. The main result of the present paper is an extension of this to the

[^1]mixed case, where the fewnomials may have have different supports $A_{i}$. Our bound depends on the combinatorial structure of the Minkowski sum $P_{1}+\ldots+P_{n}$ through the number of its vertices. We remark that our proof is quite different from the one in [8], which is rather indirect. Clearly, the number $V_{0}\left(P_{i}\right)$ of vertices of $P_{i}$ is at most $t_{i}$. Moreover, $V_{0}\left(P_{1}+\ldots+P_{n}\right) \leq V_{0}\left(P_{1}\right) \cdots V_{0}\left(P_{n}\right)$ and this bound is known to be sharp [15].

Theorem 1.1. If the $A_{i} \subseteq \mathbb{R}^{n}$ are finite nonempty sets of cardinality $t_{i}$ and with convex hull $P_{i}$, for $i=1, \ldots, n$, then

$$
\mathbb{E}\left(A_{1}, \ldots, A_{n}\right) \leq(2 \pi)^{-\frac{n}{2}} V_{0}\left(t_{1}-1\right) \ldots\left(t_{n}-1\right)
$$

Here $V_{0}$ denotes the number of vertices of the Minkowski sum $P:=P_{1}+\ldots+P_{n}$.

The bound in this theorem looks similar to the one in a conjecture attributed to Kushnirenko, which states that the number of positive nondegenerate zeros is always bounded by $\left(t_{1}-1\right) \cdots\left(t_{n}-1\right)$. However, this was disproved in [17], already in the special case $n=2 .{ }^{2}$

In the unmixed situation, where all supports equal $A$, it is well known [12] that the expected number of positive zeros can be expressed by the volume of the image of the Veronese like map $\mathbb{R}_{>0}^{n} \rightarrow \mathbb{P}\left(\mathbb{R}^{A}\right)$ sending $x$ to $\left[x^{a}\right]_{a \in A}$. This is a consequence of the kinematic formula for real projective spaces. In the mixed situation, there is no such simple characterization: we work with the more complicated kinematic formula for products of projective spaces (Theorem 3.2) that we derive from $[9,19]$. After passing to exponential coordinates $w=\log x$, we bound the resulting integral over $\mathbb{R}^{n}$ with a strategy inspired by the theory of toric varieties. The normal fan of the polytope $P$ affords a decomposition of $\mathbb{R}^{n}$ into the normal cones $C$ at the vertices of $P$. The resulting integral over $C$ can be bounded in terms of the characteristic function of the dual cone of $C$. Finally, an explicit a priori bound on this characteristic function (Proposition 2.4) completes the argument.

### 1.1 The univariate case and a conjecture

The univariate case ( $n=1$ ) was settled, up to multiplicative constants, by Jindal et al. [20]. They showed that for any subset $S \subseteq \mathbb{R}$ of cardinality $t$, we have

$$
\begin{equation*}
\mathbb{E}(S) \leq \frac{2}{\pi} \sqrt{t-1} \tag{1.1}
\end{equation*}
$$

Moreover, they constructed a sequence $S_{t} \subseteq \mathbb{Z}$ of supports of cardinality $t$ with $\mathbb{E}\left(S_{t}\right) \geq c \sqrt{t}$ for some constant $c>0$. Consider for $t_{1}, \ldots, t_{n} \geq 1$ the supports $A_{1}:=S_{t_{1}} \times 0 \ldots \times$ $0, \ldots, A_{n}:=0 \times \ldots \times 0 \times S_{t_{n}}$. These supports describe a system of $n$ equations, where the $i$ th equation depends on $x_{i}$ only. Therefore, $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=\mathbb{E}\left(S_{t_{1}}\right) \cdots \mathbb{E}\left(S_{t_{n}}\right)$, which with the above leads to the lower bound

$$
\begin{equation*}
\mathbb{E}\left(A_{1}, \ldots, A_{n}\right) \geq c^{n} \sqrt{t_{1} \cdots t_{n}} \tag{1.2}
\end{equation*}
$$

[^2]We complement this by showing that for any $A=S_{1} \times \ldots \times$ $S_{n}$ in product form, the expectation $\mathbb{E}(A, \ldots, A)$ can be expressed in terms of the $\mathbb{E}\left(S_{i}\right)$ as follows.
Proposition 1.2. If $A=S_{1} \times \ldots \times S_{n}$ for finite $S_{i} \subseteq \mathbb{R}$, then

$$
\mathbb{E}(A, \ldots, A)=\pi^{n}\left(\operatorname{vol}\left(\mathbb{P}^{n}\right)\right)^{-1} \mathbb{E}\left(S_{1}\right) \cdots \mathbb{E}\left(S_{n}\right)
$$

We conjecture that the lower bound (1.2) is optimal in the following sense.

Conjecture 1. Let $A_{i} \subseteq \mathbb{R}^{n}$ be finite nonempty sets of cardinality $t_{i}$ with convex hull $P_{i}$, for $i=1, \ldots, n$. We denote by $V_{0}$ the number of vertices of $P_{1}+\ldots+P_{n}$. Then

$$
\mathbb{E}\left(A_{1}, \ldots, A_{n}\right) \leq \kappa\left(n, V_{0}\right) \sqrt{t_{1} \cdots t_{n}}
$$

for some function $\kappa: \mathbb{N}^{2} \rightarrow \mathbb{N}$. In particular, for $A \subseteq \mathbb{R}^{n}$ of cardinality $t$, we have $\mathbb{E}(A, \ldots, A) \leq \kappa\left(n, V_{0}\right) t^{\frac{n}{2}}$.

In the special case $A=S_{1} \times \ldots \times S_{n}$, by combining (1.1) with Proposition 1.2 , we obtain $\mathbb{E}(A, \ldots, A) \operatorname{vol}\left(\mathbb{P}^{n}\right) \leq 2^{n} \sqrt{t}$ with $t=\# A$, which is smaller than what Conjecture 1 predicts.

### 1.2 Improvement in unmixed case

We can exponentially improve the dependence on $n$ in the bound of Theorem 1.1 in the case where all supports are equal. (Note $\operatorname{vol}\left(\mathbb{P}^{n}\right)^{-1}=\Gamma\left(\frac{n+1}{2}\right) \pi^{-\frac{n+1}{2}}$.)
Proposition 1.3. For $A \subseteq \mathbb{R}^{n}$ of cardinality $t \geq 1$ with convex hull $P$ and $V_{0}$ vertices, we have

$$
\mathbb{E}(A, \ldots, A) \leq \frac{1}{\operatorname{vol}\left(\mathbb{P}^{n}\right)} V_{0}\binom{t-1}{n}
$$

Unfortunately, this bound has exponentially worse dependence on $n$ than the bound $\mathbb{E}(A, \ldots, A) \leq 2^{1-n}\binom{t}{n}$ in [8]. For instance, for $t=n+k$ with fixed $k, \mathbb{E}(A, \ldots, A)$ goes to 0 exponentially fast as $n \rightarrow \infty$ by [8], so the system has no nondegenerate zero with overwhelming probability. The bound in Proposition 1.3 is too weak to reveal this!
Remark 1.4. The bound in [8] also holds for nonstandard centered Gaussian coefficients $c(a) \sim N\left(0, \sigma(a)^{2}\right)$. In this situation, our proof of Theorem 1.3 only leads to an upper bound with the additional factor $\left(\max _{a} \sigma(a) / \min _{a} \sigma(a)\right)^{n}$ (similarly for Theorem 1.1).

### 1.3 Location of zeros

We finish with a result on the typical location of the zeros. It is well known that for certain random real polynomials, the positive reals zeros $x$ tend to accumulate around 1: see [12] for the dense and [20] for the sparse case. This means that $w=\log x$ accumulates around 0 . We generalize this to multivariate systems as follows.

Theorem 1.5. Fix a finite supports $A_{1} \ldots, A_{n} \subseteq \mathbb{R}^{n}$ and consider a random system (4.3) with independent standard Gaussian coefficients $c_{i}(a)$ for the stretched supports $m A_{i}$, where
$m \in \mathbb{Z}_{>0}$. Fix $\varepsilon>0$. Then the probability that the system has a zero $w \in \mathbb{R}^{n}$ with $\|w\|>\varepsilon$ goes to zero, as $m \rightarrow \infty$.

There are sophisticated results on the distributions of complex zeros of random fewnomials systems [35, 36].

## 2 Preliminaries

### 2.1 Metric properties of charts of projective space

Consider the real projective space $\mathbb{P}^{m}$. We shall identify the tangent space $T_{[y]} \mathbb{P}^{m}$ at a point $[y]:=\left[y_{0}: \ldots: y_{m}\right]$ with $\mathbb{R} y^{\perp}$. The standard Riemannian metric on $\mathbb{P}^{m}$ is defined by $\langle v, w\rangle_{[y]}:=\|y\|^{-2}\langle v, w\rangle$ for $v, w \in \mathbb{R} y^{\perp}$. We denote by $P_{y}$ the orthogonal projection onto $\mathbb{R} y^{\perp}$.

Consider the affine chart $\left(\mathbb{P}^{m}\right)_{y_{0} \neq 0} \rightarrow \mathbb{R}^{m}$, which maps [ $y_{0}: \ldots: y_{m}$ ] to $y_{0}^{-1}\left(y_{1}, \ldots, y_{m}\right)$. Its inverse is given by

$$
\pi: \mathbb{R}^{m} \rightarrow\left(\mathbb{P}^{m}\right)_{y_{0} \neq 0},\left(y_{1}, \ldots, y_{m}\right) \mapsto\left[1: y_{1}: \ldots: y_{m}\right]
$$

By [6, Lemma 14.8], the derivative of $\pi$ at $y^{\prime}:=\left(y_{1}, \ldots, y_{m}\right)$ satisfies $D_{y^{\prime}} \pi=\left\|\pi\left(y^{\prime}\right)\right\|^{-1} P_{y}$, and therefore,

$$
\begin{equation*}
\left\|D_{y^{\prime}} \pi\right\| \leq\left\|\pi\left(y^{\prime}\right)\right\|^{-1} \leq 1 . \tag{2.1}
\end{equation*}
$$

### 2.2 On the quantity $\sigma$

The relative position of two subspaces of a Euclidean vector space $E$ can be quantified by a volume-like quantity, which is crucial in the study of integral geometry in homogeneous spaces; see [19] and [9, §3.3]. To define this quantity, note first that there is an induced inner product on the exterior algebra $\Lambda(E)$ given by [9, (2.1)]

$$
\left\langle v_{1} \wedge \cdots \wedge v_{k}, w_{1} \wedge \cdots \wedge w_{k}\right\rangle=\operatorname{det}\left(\left\langle v_{i}, w_{j}\right\rangle\right)_{1 \leq i, j \leq k}
$$

More concretely, $\left\|v_{1} \wedge \ldots \wedge v_{n}\right\|=\left|\operatorname{det}\left[v_{1}, \ldots, v_{n}\right]\right|$, where [ $v_{1}, \ldots, v_{n}$ ] denotes the matrix with columns $v_{i} \in E=\mathbb{R}^{n}$

Let $V, W$ be linear subspaces of $E$ of complementary dimensions. We define [9, (3.3)]

$$
\begin{equation*}
\sigma(V, W):=\left\|v_{1} \wedge \ldots \wedge v_{k} \wedge w_{1} \wedge \ldots \wedge w_{m}\right\| \in[0,1] \tag{2.2}
\end{equation*}
$$

where $v_{1}, \ldots, v_{k}$ and $w_{1}, \ldots, w_{m}$ are orthonormal bases of $V$ and $W$, respectively. Clearly, $\sigma(V, W)=\sigma(W, V)$. Here are the extreme cases: $\sigma(V, W)=0$ iff $V \cap W \neq 0$ and $\sigma(V, W)=$ 1 iff $v$ and $W$ are orthogonal. We refer to Appendix A for the proof of the following easy observation.

Proposition 2.1. We have $\sigma\left(V^{\perp}, W^{\perp}\right)=|\operatorname{det} p|$, if the map $p: V^{\perp} \rightarrow W$ denotes the restriction of the orthogonal projection $E \rightarrow W$ to $V^{\perp}$. Moreover, $\sigma(V, W)=\sigma\left(V^{\perp}, W^{\perp}\right)$.

Clearly, the definition (2.2) can be extended to more than two subspaces; see [9, (3.5)]. But if $W=W_{1} \oplus \ldots \oplus W_{n}$ is an orthogonal decomposition, we can reduce to the case of two subspace [9, Lemma A.6].

$$
\begin{equation*}
\sigma\left(V, W_{1}, \ldots, W_{n}\right)=\sigma\left(V, W_{1}+\ldots+W_{n}\right) \tag{2.3}
\end{equation*}
$$

### 2.3 Characteristic functions of convex cones

We prove here an priori upper bound on the characteristic function of a convex cone, which is a key ingredient in the proof of Theorem 1.1.

A convex cone $C \subseteq \mathbb{R}^{n}$ is called proper if it is $n$-dimensional and pointed, i.e., full-dimensional and contained in a halfspace. It is well known that a convex $C \subseteq \mathbb{R}^{n}$ is proper iff its dual cone

$$
C^{*}:=\left\{x \in \mathbb{R}^{n} \mid \forall y \in C\langle x, y\rangle \geq 0\right\}
$$

is proper. Let $g \in \mathrm{GL}(n, \mathbb{R})$. Then $K:=g(C)$ is a proper cone and $g^{T}\left(K^{*}\right)=C^{*}$. We denote by $\operatorname{int}(C)$ the interior of $C$.

We assign to a proper cone $C \subseteq \mathbb{R}^{n}$ the function

$$
\begin{equation*}
v_{C}: \operatorname{int}\left(C^{*}\right) \rightarrow \mathbb{R}_{>0}, v_{C}(x):=\int_{C} e^{-\langle x, y\rangle} d y \tag{2.4}
\end{equation*}
$$

One calls $v_{C}$ the characteristic function (or Koszul-Vinberg characteristic) of $C^{*}$. It is a useful analytic tool for investigating convex cones, e.g., see [13, I.3] and [16]. E.g., $\mathbb{R}_{>0}^{n}$ is self dual and $v_{\mathbb{R}_{>0}^{n}}(x)=\left(x_{1} \cdot \ldots \cdot x_{n}\right)^{-1}$ for $x \in \mathbb{R}_{>0}^{n}$.

The homogeneity property $v_{C}(t x)=t^{-n} v_{C}(x)$ for $t>0$, $x \in \operatorname{int}\left(C^{*}\right)$ is immediate to check. Moreover, the transformation formula implies the following invariance property: if $g \in \mathrm{GL}(n, \mathbb{R})$ and $K:=g(C)$, then $g^{T}\left(K^{*}\right)=C^{*}$ and

$$
\begin{equation*}
v_{K}(z)=|\operatorname{det} g| v_{C}\left(g^{T} z\right) \quad \text { for } z \in \operatorname{int}\left(K^{*}\right) \tag{2.5}
\end{equation*}
$$

Remark 2.2. The function $\log v_{C}$ is strictly convex and essentially equals Nesterov and Nemirowski's universal selfconcordant barrier function [31, §2.5], see [16] for the proof.

The following is well known, e.g., see [16, Thm. 4.1]. Appendix B contains the proof for the sake of completeness.

Lemma 2.3. We have $v_{C}(x)=n!\operatorname{vol}\{y \in C \mid\langle x, y\rangle \leq 1\}$ for $x \in \operatorname{int}\left(C^{*}\right)$.

The following is essential for the proof of Theorem 1.1.
Proposition 2.4. Let $C \subseteq \mathbb{R}^{n}$ be a proper cone. Then we have for $b_{1}, \ldots, b_{n} \in C^{*}$.

$$
\left|\operatorname{det}\left[b_{1}, \ldots, b_{n}\right]\right| \cdot v_{C}\left(b_{1}+\ldots+b_{n}\right) \leq 1
$$

This bound is optimal.
Proof. We denote by cone $\left(b_{1}, \ldots, b_{n}\right) \subseteq C^{*}$ the convex cone generated by $b_{1}, \ldots, b_{n}$. Without loss of generality, we may assume that $b_{1}, \ldots, b_{n} \in C^{*}$ is a basis of $\mathbb{R}^{n}$. Let $b_{1}^{*}, \ldots, b_{n}^{*}$ denote its dual basis, that is $\left\langle b_{i}^{*}, b_{j}\right\rangle=\delta_{i j}$. In matrix terminology, this means $\left[b_{1}^{*}, \ldots, b_{n}^{*}\right]^{T}\left[b_{1}, \ldots, b_{n}\right]=I_{n}$, hence

$$
\begin{equation*}
\operatorname{det}\left[b_{1}^{*}, \ldots, b_{n}^{*}\right] \operatorname{det}\left[b_{1}, \ldots, b_{n}\right]= \pm 1 \tag{2.6}
\end{equation*}
$$

The definition of the dual basis implies that cone $\left(b_{1}^{*}, \ldots, b_{n}^{*}\right)$ is the dual cone of cone $\left(b_{1}, \ldots, b_{n}\right)$. Therefore, by duality, we get

$$
C \subseteq \operatorname{cone}\left(b_{1}, \ldots, b_{n}\right)^{*}=\operatorname{cone}\left(b_{1}^{*}, \ldots, b_{n}^{*}\right)
$$

Put $d:=b_{1}+\ldots+b_{n}$ and let $y \in C$ such that $\langle d, y\rangle \leq 1$. Since $C \subseteq \operatorname{cone}\left(b_{1}^{*}, \ldots, b_{n}^{*}\right)$, we can write $y=\sum_{i} t_{i} b_{i}^{*}$ with
$t_{i} \geq 0$. Moreover $\sum_{i} t_{i}=\langle d, y\rangle \leq 1$. Thus we have shown the inclusion

$$
K:=\{y \in C \mid\langle d, y\rangle \leq 1\} \subseteq \operatorname{conv}\left\{0, b_{1}^{*}, \ldots, b_{n}^{*}\right\} .
$$

This implies the inequality of volumes

$$
\operatorname{vol}_{n} K \leq \operatorname{vol}_{n} \operatorname{conv}\left\{0, b_{1}^{*}, \ldots, b_{n}^{*}\right\}=\frac{1}{n!}\left|\operatorname{det}\left[b_{1}^{*}, \ldots, b_{n}^{*}\right]\right| .
$$

Multiplying with $n!\left|\operatorname{det}\left[b_{1}, \ldots, b_{n}\right]\right|$, using (2.6) and taking into account Lemma 2.3, the assertion follows.

The optimality is attained for $C=\mathbb{R}_{>0}^{n}$ and $b_{i}=d_{i} e_{i}$ with $d_{i}>0$. Indeed, we have

$$
\left|\operatorname{det}\left[b_{1}, \ldots, b_{n}\right]\right| \cdot v_{C}(d)=d_{1} \cdot \ldots \cdot d_{n}\left(d_{1} \cdot \ldots \cdot d_{n}\right)^{-1}=1
$$

### 2.4 Vertices and normal fan of sums of polytopes

We recall here some basic facts about polytopes and their normal fans; see [39, §7.1] for more details.

Let $P \subseteq \mathbb{R}^{n}$ be a full-dimensional polytope and $v$ be a vertex of $P$. The cone $P_{v}$ of $P$ at $v$ is defined as the convex cone generated by $P-v$. It is a proper cone. The dual cone of $P_{v}$, also called the inner normal cone of $P$ at $v$, is defined as

$$
P_{v}^{*}:=\left\{y \in \mathbb{R}^{n} \mid \forall x \in P\langle x-v, y\rangle \geq 0\right\} .
$$

The cone $P_{v}^{*}$ is also proper. The union over all $P_{v}^{*}$ equals $\mathbb{R}^{n}$. Moreover, for $v_{1} \neq v_{2}$, we have $\operatorname{dim}\left(P_{v_{1}}^{*} \cap P_{v_{2}}^{*}\right)<n$. In fact, the $P_{v}^{*}$ are the $n$-dimensional cones of the normal fan of $P$.

We will need the following result.
Lemma 2.5. Let $P_{1}, \ldots, P_{n}$ be polytopes in $\mathbb{R}^{n}$. There is an injective map
$\operatorname{Vert}\left(P_{1}+\ldots+P_{n}\right) \rightarrow \operatorname{Vert}\left(P_{1}\right) \times \ldots \operatorname{Vert}\left(P_{n}\right), v \mapsto\left(v_{1}, \ldots, v_{n}\right)$
satisfying $v=v_{1}+\ldots+v_{n}$. Moreover, if we denote by $\Pi_{i}$ the cone of $P_{i}$ at the vertex $v_{i}$, then $\Pi:=\Pi_{1}+\ldots+\Pi_{n}$ is the cone of $P_{1}+\ldots+P_{n}$ at the vertex $v_{1}+\ldots+v_{n}$. In particular, $\Pi^{*}=\Pi_{1}^{*} \cap \ldots \cap \Pi_{n}^{*}$.

Proof. To a nonzero weight $\omega \in \mathbb{R}^{n}$ we assign the face of $P_{i}$, given by

$$
F\left(P_{i}, \omega\right):=\left\{w \in \mathbb{R}^{n} \mid\langle w, \omega\rangle=\min _{w^{\prime} \in P_{i}}\left\langle w^{\prime}, \omega\right\rangle\right\} .
$$

We have by [34, Thm. 1.7.5]

$$
F\left(P_{1}+\ldots+P_{n}, \omega\right)=F\left(P_{1}, \omega\right)+\ldots+F\left(P_{n}, \omega\right) .
$$

Suppose that $F\left(P_{1}+\ldots+P_{n}, \omega\right)=\{v\}$ is a vertex. Then all $F\left(P_{i}, \omega\right)=\left\{v_{i}\right\}$ are vertices and $v=v_{1}+\cdots+v_{n}$. The $v_{i}$ are uniquely determined by $v$, see [14, Prop. 2.1]. Then the map $v \mapsto\left(v_{1}, \ldots, v_{n}\right)$ is as required. The remaining assertions are clear.

Lemma 2.5 implies $V_{0}\left(P_{1}+\ldots+P_{n}\right) \leq V_{0}\left(P_{1}\right) \cdots V_{0}\left(P_{n}\right)$. This bound is sharp, see [15, 21].

## 3 Random intersections in products of projective spaces

### 3.1 The kinematic formula

We specialize here the general kinematic formula for homogeneous spaces from [9, Thm. A.2] to the case of products of real projective spaces (Theorem 3.2). For this purpose, we define the average scaling factor and we explain how to bound it in Lemma 3.5.

Consider the product $\Omega:=\mathbb{P}^{m_{1}} \times \cdots \times \mathbb{P}^{m_{n}}$ of real projective spaces. The product $G:=O\left(m_{1}+1\right) \times \cdots \times O\left(m_{n}+1\right)$ of orthogonal groups acts transitively on $\Omega$. So $\Omega$ is a homogeneous space and we have an induced transitive action of $G$ on the tangent bundle of $\Omega$. We focus on the special hypersurfaces $H_{1}, \ldots, H_{n}$ of $\Omega$ of the following shape
$H_{1}:=\mathbb{P}^{m_{1}-1} \times \mathbb{P}^{m_{2}} \times \cdots \times \mathbb{P}^{m_{n}}, \ldots, H_{n}:=\mathbb{P}^{m_{1}} \times \mathbb{P}^{m_{2}} \cdots \times \mathbb{P}^{m_{n}-1}$.
They are determined upon selecting hyperplanes $\mathbb{P}^{m_{i}-1}$ in each $\mathbb{P}^{m_{i}}$. Our goal is to investigate the average cardinality of the intersection $Z \cap H_{1} \cap \ldots \cap H_{n}$ of an $n$-dimensional smooth submanifold $Z \subseteq \Omega$ with random $H_{i}$, which are defined by replacing the fixed $\mathbb{P}^{m_{i}-1}$ by independently chosen uniform random hyperplanes in $\mathbb{P}^{m_{i}}$.

Fix a distinguished point $\omega \in \Omega$ and denote by $K$ the stabilizer group of $\omega$. E.g., take $\omega_{i}=[1: 0 \ldots: 0]$ for all $i$. Notice that we have an induced action of $K$ on the tangent space $T:=T_{\omega} \Omega$, which we can identify with the standard action of $K=O\left(m_{1}\right) \times \cdots \times O\left(m_{n}\right)$ on $T=\mathbb{R}^{m_{1}} \times \cdots \times \mathbb{R}^{m_{n}}$. This induces an action of $K$ on the Grassmann manifold $\operatorname{Gr}(d, T)$ of linear subspaces of $T$ with codimension $d$. Note that this action is transitive if $n=1$, but not for $n \geq 2$.

We assign to an $n$-dimensional smooth submanifold $Z \subseteq$ $\Omega$ a map

$$
\begin{equation*}
Z \rightarrow \operatorname{Gr}(n, T) / K, p \mapsto K_{g} N_{p} Z \tag{3.2}
\end{equation*}
$$

as follows. For given $p \in Z$ choose any $g \in G$ such that $g p=$ $\omega$. The induced action of $g$ maps the tangent space $T_{p} \Omega$ to $T_{\omega} \Omega=T$. This transports the normal subspace $N_{p} Z \subseteq T_{p} \Omega$ of $Z$ at $p$ to $g N_{p} Z \subseteq T$. Note that the $K$-orbit of the subspace $g N_{p} Z$ does not depend on the choice of $g$, which shows that the map (3.2) is well defined.

We call the submanifold $Z$ cohomogeneous if the map (3.2) is constant; see [9, A.5.1] and [30]. For instance, a product $Z=\mathcal{L}_{1} \times \ldots \times \mathcal{L}_{n}$ of lines $\mathcal{L}_{i}$ in $\mathbb{P}^{m_{i}}$ is cohomogeneous: indeed, the map (3.2) sends any point $p \in Z$ to the $K$-orbit of $\mathbb{R} \times \ldots \times \mathbb{R}$.

Definition 3.1. The average scaling factor function of the $n$-dimensional submanifold $Z$ of $\mathbb{P}^{m_{1}} \times \cdots \times \mathbb{P}^{m_{n}}$ is the function $\bar{\sigma}_{Z}: Z \rightarrow[0,1]$ defined at $p \in Z$ by

$$
\bar{\sigma}_{Z}(p):=\mathbb{E}_{L_{i}} \sigma\left(g N_{p} Z, L_{1} \times \ldots \times L_{n}\right),
$$

where $g \in G$ satisfies $g p=\omega$, and the expectation is taken over uniformly random lines $L_{i}$ in $T=\mathbb{R}^{m_{1}} \times \cdots \times \mathbb{R}^{m_{n}}$; see (2.2) for the definition of $\sigma$.

Note that due to the averaging over the $K$-orbit, the choice of $g$ is irrelevant. The above definition is consistent with the one in [9, Def. A.1], since

$$
\begin{align*}
& \sigma\left(g N_{p} Z, L_{1} \times \ldots \times L_{n}\right) \\
& \quad=\sigma\left(g N_{p} Z, L_{1} \times 0 \times \cdots \times 0, \ldots, 0 \times \cdots \times 0 \times L_{n}\right) \tag{3.3}
\end{align*}
$$

by (2.3); indeed note that the $n$ lines $L_{1} \times 0 \times \cdots \times 0, \ldots$ are pairwise orthogonal.

We introduce the notation

$$
\rho_{n}:=\mathbb{E}\|x\|=\sqrt{2} \frac{\Gamma\left(\frac{n+1}{2}\right)}{\Gamma\left(\frac{n}{2}\right)} \leq \sqrt{n}
$$

for standard Gaussian $x \in \mathbb{R}^{n}$ and note that [6, Lemma 2.25],

$$
\begin{equation*}
\frac{\operatorname{vol}\left(\mathbb{P}^{m_{i}-1}\right)}{\operatorname{vol}\left(\mathbb{P}^{m_{i}}\right)}=\frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{m_{i}+1}{2}\right)}{\Gamma\left(\frac{m_{i}}{2}\right)}=\frac{1}{\sqrt{2 \pi}} \rho_{m_{i}} \tag{3.4}
\end{equation*}
$$

We can now explicitly state the kinematic formula for products of real projective spaces.

Theorem 3.2. For anyn-dimensional submanifold $Z$ of $\mathbb{P}^{m_{1}} \times$ $\cdots \times \mathbb{P}^{m_{n}}$, we have
$\mathbb{E}_{g \in G^{\#}}\left(Z \cap g_{1} H_{1} \cap \ldots \cap g_{n} H_{n}\right)=(2 \pi)^{-\frac{n}{2}} \rho_{m_{1}} \cdots \rho_{m_{n}} \int_{Z} \bar{\sigma}_{Z} d Z$, where the hypersurfaces $H_{i}$ are defined in (3.1).

Proof. If $\sigma_{K}: Z \times H_{1} \times \ldots \times H_{n} \rightarrow[0,1]$ denotes the average scaling function from [9, Def. A.1], then [9, Thm. A.2] states that

$$
\begin{aligned}
& \mathbb{E}_{g \in G} \#\left(Z \cap g_{1} H_{1} \cap \ldots \cap g_{n} H_{n}\right) \\
& \quad=\frac{1}{\operatorname{vol}(\Omega)^{n}} \int_{Z \times H_{1} \times \ldots \times H_{n}} \sigma_{K} d\left(Z \times H_{1} \times \ldots \times H_{n}\right) .
\end{aligned}
$$

By $K$-invariance and (3.3), we have $\sigma_{K}\left(z, y_{1}, \ldots, y_{n}\right)=\bar{\sigma}_{Z}(z)$ for all $z \in Z$ and $y_{i} \in H_{i}$. Therefore,

$$
\mathbb{E}_{g \in G} \#\left(Z \cap g_{1} H_{1} \cap \ldots \cap g_{n} H_{n}\right)=\frac{\operatorname{vol}\left(H_{1}\right) \cdots \operatorname{vol}\left(H_{n}\right)}{\operatorname{vol}(\Omega)^{n}} \int_{Z} \bar{\sigma}_{Z} d Z
$$

Finally, (3.4) gives

$$
\frac{\operatorname{vol}\left(H_{1}\right) \cdots \operatorname{vol}\left(H_{n}\right)}{\operatorname{vol}(\Omega)^{n}}=\prod_{i=1}^{n} \frac{\operatorname{vol}\left(\mathbb{P}^{m_{i}-1}\right)}{\operatorname{vol}\left(\mathbb{P}^{m_{i}}\right)}=\frac{\rho_{m_{1}} \cdots \rho_{m_{n}}}{(2 \pi)^{\frac{n}{2}}}
$$

which completes the proof.
Example 3.3. A product $Z=\mathcal{L}_{1} \times \ldots \times \mathcal{L}_{n}$ of lines $\mathcal{L}_{i}$ is cohomogeneous and we have $\bar{\sigma}_{Z}=(2 / \pi)^{n / 2}\left(\rho_{m_{1}} \cdots \rho_{m_{n}}\right)^{-1}$ by Theorem 3.2.

We shall focus on submanifolds $Z$ arising as the image of an injective map

$$
\begin{equation*}
\psi: U \rightarrow \mathbb{P}^{m_{1}} \times \cdots \times \mathbb{P}^{m_{n}}, \psi(x):=\left(\psi_{1}(x), \ldots, \psi_{n}(x)\right) \tag{3.5}
\end{equation*}
$$

where the $\psi_{i}: U \rightarrow \mathbb{P}^{m_{i}}$ are smooth maps defined on an open subset $U \subseteq \mathbb{R}^{n}$. Let us denote by

$$
J \psi(x):=\sqrt{\operatorname{det}\left(\left(D_{x} \psi\right)^{T} D_{x} \psi\right)}
$$

the absolute facobian of $\psi$ at $x$. The transformation formula implies that

$$
\begin{equation*}
\int_{Z} \bar{\sigma}_{Z} d Z=\int_{U} \bar{\sigma}_{Z}(\psi(x)) J \psi(x) d x \tag{3.6}
\end{equation*}
$$

We next analyze the integrand on the right-hand side more closely.
Lemma 3.4. Let $x \in U$ and put $T_{i}:=T_{\psi_{i}(x)} \mathbb{P}^{m_{i}}$. Let $\lambda_{1}, \ldots, \lambda_{n}$ be independent standard Gaussian linear forms on $T_{i}$. This defines the random linear forms $\lambda_{i} \circ D_{x} \psi_{i}$ on $\mathbb{R}^{n}$. Then

$$
\begin{aligned}
& \rho_{m_{1}} \cdots \rho_{m_{n}} \bar{\sigma}_{Z}(\psi(x)) J \psi(x) \\
& \quad=\mathbb{E}_{\lambda_{1}, \ldots, \lambda_{n}}\left\|\left(\lambda_{1} \circ D_{x} \psi_{1}\right) \wedge \ldots \wedge\left(\lambda_{n} \circ D_{x} \psi_{n}\right)\right\| .
\end{aligned}
$$

Proof. To simplify notation, we assume w.l.o.g. that $\omega=\psi(x)$ is the distinguished point. We also identify $T_{i}$ with $\mathbb{R}^{m_{i}}$. For $u_{i} \in T_{i}$ with $\left\|u_{i}\right\|=1$ consider the line $L_{i}=\mathbb{R} u_{i}$ and the orthogonal projection $p_{i}: T_{i} \rightarrow L_{i}$, which is is given by $p_{i}(w)=\mu_{i}(w) u_{i}$ with the linear form on $T_{i}$ defined by $\mu_{i}(w):=\left\langle w, u_{i}\right\rangle$. Thus the orthogonal projection $p_{L}: T_{1} \times$ $\cdots \times T_{n} \rightarrow L_{1} \times \cdots \times L_{n}$ is described by $\mu_{1}, \ldots, \mu_{n}$. This implies that

$$
\begin{equation*}
\left|\operatorname{det}\left(p_{L} \circ D_{x} \psi\right)\right|=\left\|\left(\mu_{1} \circ D_{x} \psi_{1}\right) \wedge \ldots \wedge\left(\mu_{n} \circ D_{x} \psi_{n}\right)\right\| \tag{3.7}
\end{equation*}
$$

On the other hand, according to Proposition 2.1, we have

$$
\sigma\left(L_{1} \times \cdots \times L_{n}, N_{p} Z\right)=\left|\operatorname{det} p_{L}^{\prime}\right|
$$

where $p_{L}^{\prime}: T_{p} Z \rightarrow L_{1} \times \cdots \times L_{n}$ denotes the restriction of $p_{L}$ to $T_{p} Z$. Applying the determinant to the composition of $D_{x} \psi$ with $p_{L}^{\prime}$, we get

$$
J \psi(x)\left|\operatorname{det} p_{L}^{\prime}\right|=\left|\operatorname{det}\left(p_{L} \circ D_{x} \psi\right)\right|
$$

By averaging over random lines $L_{i}$, we deduce from the definition of $\bar{\sigma}_{Z}$ and the above that

$$
\begin{aligned}
& J \psi(x) \bar{\sigma}_{Z}(p)=J \psi(x) \mathbb{E}_{L_{i}} \sigma\left(N_{p} Z, L_{1} \times \cdots \times L_{n}\right) \\
& \quad=J \psi(x) \mathbb{E}_{L_{i}}\left|\operatorname{det} p_{L}^{\prime}\right|=\mathbb{E}_{L_{i}}\left|\operatorname{det}\left(p_{L} \circ D_{\psi}\right)\right|
\end{aligned}
$$

Finally, a standard Gaussian linear form on $T_{i}$ is obtained as $\lambda_{i}=r_{i} \mu_{i}$ with independent random variables $r_{i}$ and $u_{i}$, where $u_{i}$ is uniformly random in the unit sphere of $T_{i}$ and $r_{i}^{2}$ is $\chi^{2}$-distributed with $m_{i}$ degrees of freedom. Thus $\mathbb{E} r_{i}=$ $\rho_{m_{i}}$. Altogether, we obtain, using (3.7),

$$
\begin{gathered}
\rho_{m_{1}} \cdots \rho_{m_{n}} J \psi(x) \bar{\sigma}_{Z}(p)=\rho_{m_{1}} \cdots \rho_{m_{n}} \mathbb{E}\left|\operatorname{det}\left(p_{L} \circ D_{\psi}\right)\right| \\
=\rho_{m_{1}} \cdots \rho_{m_{n}} \mathbb{E}\left\|\left(\mu_{1} \circ D_{x} \psi_{1}\right) \wedge \ldots \wedge\left(\mu_{n} \circ D_{x} \psi_{n}\right)\right\| \\
=\mathbb{E}\left\|\left(\lambda_{1} \circ D_{x} \psi_{1}\right) \wedge \ldots \wedge\left(\lambda_{n} \circ D_{x} \psi_{n}\right)\right\|,
\end{gathered}
$$

which completes the proof.

### 3.2 Bounding the average scaling factor

In order to bound the quantity in Lemma 3.4, we use affine charts for the product of projective spaces. Let $y_{i 0}, \ldots, y_{i m_{i}}$ be coordinates for $\mathbb{P}^{m_{i}}$. Fix $0 \leq r_{i} \leq m_{i}$ for $i=1, \ldots, n$, and consider the inverse of the affine chart $\pi_{i r_{i}}: \mathbb{R}^{m_{i}} \rightarrow$ $\left(\mathbb{P}^{m_{i}}\right)_{y_{i r_{i} \neq 0}}$, see Subsection 2.1. We describe the maps $\psi_{i}$ from
(3.5) in these charts by smooth functions defined on open subsets of $\mathbb{R}^{n}$,

$$
\begin{equation*}
\varphi_{i r_{i}}: \mathbb{R}^{n} \supseteq U_{i r_{i}} \rightarrow \mathbb{R}^{m_{i}} \tag{3.8}
\end{equation*}
$$

satisfying $\psi_{i}:=\pi_{i r_{i}} \circ \varphi_{i r_{i}}$. In order to simplify notation, we assume w.l.og. $r_{i}=0$ and write $\pi_{i}:=\pi_{i 0}, \varphi_{i}:=\varphi_{i 0}$. In these charts, the combined map $\psi$ of (3.5) is represented by a map

$$
\varphi: U \rightarrow \mathbb{R}^{m_{1}} \times \cdots \times \mathbb{R}^{m_{n}}, \varphi(x)=\left(\varphi_{1}(x), \ldots, \varphi_{n}(x)\right)
$$

defined on some open subset $U \subseteq \mathbb{R}^{n}$. We view the derivative $M(x):=D_{x} \varphi$ as a matrix of format $\left(m_{1}+\ldots+m_{n}\right) \times n$ with blocks $M_{i}(x):=D_{x} \varphi_{i} \in \mathbb{R}^{m_{i} \times n}$. For $1 \leq j_{i} \leq m_{i}$, $i=1, \ldots, n$, we denote by $M(x)_{j_{1}, \ldots, j_{n}}$ the $n \times n$ submatrix of $M(x)$ obtained by selecting in the $i$ th block the $j_{i}$ th row.

Lemma 3.5. Let $x \in U$ such that $\left[y_{i}\right]:=\psi_{i}(x) \in\left(\mathbb{P}^{m_{i}}\right)_{y_{i 0} \neq 0}$ for all i. Then

$$
\rho_{m_{1}} \cdots \rho_{m_{n}} \bar{\sigma}_{Z}(\psi(x)) J \psi(x) \leq \sum_{j_{1}, \ldots, j_{n}}\left|\operatorname{det} M(x)_{j_{1}, \ldots, j_{n}}\right|
$$

where the sum is over $n$-tuples $\left(j_{1}, \ldots, j_{n}\right) \in\left[m_{1}\right] \times \ldots \times\left[m_{n}\right]$.
Proof. From $\psi_{i}=\pi_{i} \circ \varphi_{i}$ we get $D \psi_{i}=D \pi_{i} \circ D \varphi_{i}$, where we drop arguments for notational simplicity. Let $\lambda_{i}: T_{i} \rightarrow \mathbb{R}$ be a linear form on $T_{i}=T_{\psi_{i}(x)} \mathbb{P}^{m_{i}}$. Then, defining $w_{i}:=\lambda_{i} \circ D \pi_{i}$,

$$
\lambda_{i} \circ D \psi_{i}=\lambda_{i} \circ D \pi_{i} \circ D \varphi_{i}=w_{i} \circ D \varphi_{i} .
$$

If we identify $\lambda_{i} \circ D_{x} \psi_{i}$ with a vector in $\mathbb{R}^{n}$ and $w_{i}$ with a vector in $\mathbb{R}^{m_{i}}$, then we have the matrix product of formats $n \times \sum_{i} m_{i}$ and $\sum_{i} m_{i} \times n$,

$$
R(x):=\left[\begin{array}{c}
\left(\lambda_{1} \circ D_{x} \psi_{1}\right)^{T}  \tag{3.9}\\
\vdots \\
\left(\lambda_{n} \circ D_{x} \psi_{1}\right)^{T}
\end{array}\right]=\left[\begin{array}{ccc}
w_{1}^{T} & 0 & \ldots 0 \\
0 & w_{2}^{T} & \ldots 0 \\
\vdots & \vdots & \vdots \\
0 & 0 & w_{n}^{T}
\end{array}\right] \cdot\left[\begin{array}{c}
M_{1}(x) \\
\vdots \\
M_{n}(x)
\end{array}\right] .
$$

Lemma 3.4 tells us that

$$
\left.\rho_{m_{1}} \cdots \rho_{m_{n}} \bar{\sigma}_{Z}(\psi(x)) J \psi(x)=\mathbb{E}_{\lambda_{i}} \mid \operatorname{det} R(x)\right) \mid
$$

where the expectation is over independent standard Gaussian $\lambda_{i}$. Note that the resulting random vector $w_{i}:=\lambda_{i} \circ D \pi_{i}$ is not standard Gaussian anymore. However $\left\|D \pi_{i}\right\| \leq 1$ by (2.1), and Lemma 3.6 below imply that $\mathbb{E} w_{i j}^{2} \leq 1$ for the $j$ th component $w_{i j}$ of $w_{i}$.

From Cauchy-Binet, we obtain from (3.9)

$$
(\operatorname{det} R(x))^{2}=\sum_{j_{1}, \ldots, j_{n}} w_{1 j_{1}}^{2} \cdots w_{n j_{n}}^{2}\left(\operatorname{det} M(x)_{j_{1}, \ldots, j_{n}}\right)^{2}
$$

where the sum is over all $\left(j_{1}, \ldots, j_{n}\right) \in\left[m_{1}\right] \times \ldots \times\left[m_{n}\right]$. Taking expectations yields

$$
\mathbb{E}_{w}(\operatorname{det} R(x))^{2} \leq \sum_{j_{1}, \ldots, j_{n}}\left(\operatorname{det} M(x)_{j_{1}, \ldots, j_{n}}\right)^{2}
$$

We conclude that

$$
\begin{aligned}
\left.\mathbb{E}_{w} \mid \operatorname{det} R(x)\right) \mid & \leq \quad\left(\mathbb{E}_{w}(\operatorname{det} R(x))^{2}\right)^{\frac{1}{2}} \\
& \leq \quad \sum_{j_{1}, \ldots, j_{n}}\left|\operatorname{det} M(x)_{j_{1}, \ldots, j_{n}}\right|
\end{aligned}
$$

which completes the proof.
Lemma 3.6. Let $A \in \mathbb{R}^{p \times m}$ with $\|A\| \leq 1$. If $y \in \mathbb{R}^{p}$ is standard Gaussian, then the random variable $z:=y A$ satisfies $\mathbb{E}\left|z_{j}\right|^{2} \leq 1$ for all $j$.
Proof. From $z_{j}=\sum_{i} y_{i} a_{i j}$ we get $z_{j}^{2}=\sum_{i, k} y_{i} y_{k} a_{i j} a_{k j}$. Hence $\mathbb{E} z_{j}^{2}=\sum_{i} a_{i j}^{2}$. Finally, $\sum_{i} a_{i j}^{2}=\left\|A\left(e_{j}\right)\right\|^{2} \leq\|A\|^{2} \leq 1$.

## 4 Mixed random fewnomial systems

We provide here the proofs of the assertions in the introduction. Let us first introduce some notation.

We assign to a real valued function $c: A \rightarrow \mathbb{R}$ on a finite nonempty subset $A \subseteq \mathbb{R}^{n}$ the real analytic function $F_{A, c}: \mathbb{R}^{n} \rightarrow \mathbb{R}$

$$
\begin{equation*}
F_{A, c}(w):=\sum_{a \in A} c(a) e^{\langle a, w\rangle} \tag{4.1}
\end{equation*}
$$

In the special case where $A$ consists of integer vectors, $F_{A, c}$ arises from the Laurent polynomial $f_{A, c}(x)=\sum_{a \in A} c(a) x^{a}$ by a substitution: $F_{A, c}(w)=f_{A, c}\left(e^{w}\right)$. Generally, we have the following equivariance property: for $g \in \operatorname{GL}(n, \mathbb{R})$ and $b \in \mathbb{R}^{n}$,

$$
\begin{equation*}
F_{A+b, b . c}(w)=e^{\langle b, w\rangle} F_{A, c}(w), F_{g(A), g . c}(w)=F_{A, c}\left(g^{T} w\right) \tag{4.2}
\end{equation*}
$$

where $b . c(a):=c(a-b)$ and $(g . c)(a):=c\left(g^{-1} a\right)$.
Suppose now we have $n$ such analytic functions encoded by $c_{i}: A_{i} \rightarrow \mathbb{R}$, for $i=1, \ldots, n$. Throughout, we denote by $t_{i}$ the cardinality of $A_{i}$ and by $P_{i}$ its convex hull. We are interested in the number $N$ of nondegenerate zeros $w \in \mathbb{R}^{n}$ of the system

$$
\begin{equation*}
F_{A_{1}, c_{1}}(w)=0, \ldots, F_{A_{n}, c_{n}}(w)=0 \tag{4.3}
\end{equation*}
$$

Our goal is to study the expected number of nondegenerate zeros for random coefficient functions. More specifically, we denote by $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)$ the expectation of $N$, when all the coefficients $c_{i}(a)$, for $i \in[n]$ and $a_{i} \in A_{i}$, are independent standard Gaussians. Clearly, $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)$ is invariant under permutations of the $A_{i}$. Also, $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=0$ if $t_{i}=1$ for some $i$. Moreover, we have $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=0$ if $\operatorname{dim}\left(P_{1}+\ldots+P_{n}\right)<n$, see Lemma 4.2.

Equation (4.2) implies the following invariance properties

$$
\begin{align*}
\mathbb{E}\left(A_{1}+b_{1}, \ldots, A_{n}+b_{n}\right) & =\mathbb{E}\left(A_{1}, \ldots, A_{n}\right), \\
\mathbb{E}\left(g\left(A_{1}\right), \ldots, g\left(A_{n}\right)\right) & =\mathbb{E}\left(A_{1}, \ldots, A_{n}\right), \tag{4.4}
\end{align*}
$$

where $b_{1}, \ldots, b_{n} \in \mathbb{R}^{n}$ and $g \in \operatorname{GL}(n, \mathbb{R})$. In particular, $\mathbb{E}$ is invariant under replacing $A_{i}$ by $\lambda_{i} A_{i}$ for $\lambda_{i} \in \mathbb{R}^{\times}$.

Our main result is Theorem 1.1 stated in the introduction. Note that it gives the correct answer $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=0$ if $t_{i}=1$ for some $i$.

Example 4.1. In the case $t_{1}=\ldots=t_{n}=2$, the $P_{i}$ are segments. If they are linearly independent, $P_{1}+\ldots+P_{n}$ is a parallelepiped with $2^{n}$ vertices. Thus, Theorem 1.1 gives $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right) \leq(2 / \pi)^{\frac{n}{2}}$. This can be easily verified directly
as follows. Suppose $A_{i}=\left\{a_{i}, b_{i}\right\}$, where $b_{1}-a_{1}, \ldots, b_{n}-a_{n}$ are linearly independent. We claim that $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=$ $2^{-n}$. For showing this, by the invariance properties (4.4), it suffices to consider the case where $A_{i}=\left\{0, e_{i}\right\}$. Then (4.3) amounts to the system $c_{i}(0)+c_{i}\left(e_{i}\right) e^{w_{i}}=0$, for $i=1, \ldots, n$, which has a solution iff $c_{i}(0) c_{i}\left(e_{i}\right)<0$, for all $i$. This happens with probability $2^{-n}$, hence indeed $\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=$ $2^{-n}$.

### 4.1 Proof of Theorem 1.1

Let us look at a special instance of (3.5). To the given finite nonempty subsets $A_{1}, \ldots, A_{n} \subseteq \mathbb{R}^{n}$, we assign the maps

$$
\psi_{i}: \mathbb{R}_{>0}^{n} \rightarrow \mathbb{P}\left(\mathbb{R}^{A_{i}}\right) \simeq \mathbb{P}^{m_{i}}, \psi_{i}(x):=\left[x^{a_{i}}\right]_{a_{i} \in A_{i}},
$$

where $m_{i}:=\# A_{i}-1$. Recall that $P_{i}$ denotes the convex hull of $A_{i}$ and put $P:=P_{1}+\ldots+P_{n}$. We consider the combined map

$$
\begin{equation*}
\psi: \mathbb{R}_{>0}^{n} \rightarrow \mathbb{P}^{m_{1}} \times \cdots \times \mathbb{P}^{m_{n}}, \psi(x):=\left(\psi_{1}(x), \ldots, \psi_{n}(x)\right) \tag{4.5}
\end{equation*}
$$

Lemma 4.2. The map $\psi$ is injective iff $P$ is $n$-dimensional. Moreover, ifP is not $n$-dimensional, then $\operatorname{rank} D_{x} \psi<n$ for all $x \in \mathbb{R}_{>0}^{n}$.

Proof. Assume $\psi(\exp (w))=\psi\left(\exp \left(w^{\prime}\right)\right)$ for $w \neq w^{\prime} \in \mathbb{R}^{n}$ Then there are $c_{i} \in \mathbb{R}$ such that for all $a_{i} \in A_{i}$ we have that $\left\langle a_{i}, w-w^{\prime}\right\rangle=c_{i}$. Hence, $\left\langle x, w-w^{\prime}\right\rangle=c_{i}$ for all $x_{i} \in P_{i}$. It follows that $\left\langle x, w-w^{\prime}\right\rangle=c_{1}+\ldots+c_{n}$ for all $x \in P$. Hence $\operatorname{dim} P<n$.

Conversely, assume there is a nonzero $w \in \mathbb{R}^{n}$ and $c \in \mathbb{R}$ such that $\langle x, w\rangle=c$ for all $x \in P$. Then there are $c_{i} \in \mathbb{R}$ such that $\left\langle x_{i}, w\right\rangle=c_{i}$ for all $x_{i} \in P_{i}$. It follows that for any $x \in \mathbb{R}_{>0}^{n}$ and any $s \in \mathbb{R}$ we have

$$
\begin{gathered}
\psi_{i}\left(e^{s w} x\right)=\left[\left(e^{s w}\right)^{a_{i}} x^{a_{i}}\right]_{a_{i} \in A_{i}}=\left[e^{s\left\langle a_{i}, w\right\rangle} x^{a_{i}}\right]_{a_{\epsilon} A_{i}} \\
=\left[e^{s c_{i}} x^{a_{i}}\right]_{a_{\in} A_{i}}=\psi_{i}(x) .
\end{gathered}
$$

Hence $\psi$ is not injective. Moreover, $w$ is in the kernel of the derivative of $\psi_{i}$ at $x$.

We denote by $Z$ the image of $\psi$. Then we can write

$$
\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=\mathbb{E}_{g \in G} \#\left(Z \cap g_{1} H_{1} \cap \ldots \cap g_{n} H_{n}\right),
$$

where the hypersurfaces $H_{i}$ are defined in (3.1). By Theorem 3.2 and (3.6), this can be expressed as

$$
\begin{equation*}
\mathbb{E}\left(A_{1}, \ldots, A_{n}\right)=(2 \pi)^{-\frac{n}{2}} \rho_{m_{1}} \cdots \rho_{m_{n}} \int_{\mathbb{R}_{>}^{n}}\left(\bar{\sigma}_{Z} \circ \psi\right) J \psi d x \tag{4.6}
\end{equation*}
$$

We make the coordinate change $\mathbb{R}^{n} \rightarrow \mathbb{R}_{>0}^{n},\left(w_{1}, \ldots, w_{n}\right) \mapsto$ $x=\left(e^{-w_{1}}, \ldots, e^{-w_{n}}\right)$, which has the absolute Jacobian $x_{1} \cdots x_{n}$, and obtain (slightly abusing notation)

$$
\begin{equation*}
\int_{\mathbb{R}_{>}^{n}}\left(\bar{\sigma}_{Z} \circ \psi\right) J \psi d x=\int_{\mathbb{R}^{n}} x_{1} \cdots x_{n}\left(\bar{\sigma}_{Z} \circ \psi\right) J \psi d w \tag{4.7}
\end{equation*}
$$

Recall from Subsection 2.4 that each vertex $v$ of $P$ defines the inner normal cone $C_{v}:=P_{v}^{*}$. We can write

$$
\begin{equation*}
\mathbb{R}^{n}=\bigcup_{v} C_{v} \tag{4.8}
\end{equation*}
$$

as the union over the vertices $v$ of $P$. Moreover, we know that $\operatorname{dim}\left(C_{v} \cap C_{v^{\prime}}\right)<n$ for different vertices $v, v^{\prime}$. Therefore, we can rewrite (4.7) as the sum

$$
\sum_{v} \int_{C_{v}} x_{1} \cdots x_{n}\left(\bar{\sigma}_{Z} \circ \psi\right) J \psi d w
$$

over the $V_{0}$ many vertices $v$ of $P$.
Fix now a vertex $v$ of $P$. According to Lemma 2.5, there are vertices $v_{i}$ of $P_{i}$, for $i=1, \ldots, n$, satisfying $v=v_{1}+\ldots+v_{n}$. Note that $a_{i} \in A_{i}$.

We define the map $\varphi_{i}: \mathbb{R}_{>0}^{n} \rightarrow \mathbb{R}^{A_{i} \backslash\left\{v_{i}\right\}}$ by

$$
\varphi_{i}(x)=\left(x^{a_{i}-v_{i}}\right)_{a_{i} \in A_{i} \backslash\left\{v_{i}\right\}} \in \mathbb{R}^{A_{i} \backslash\left\{v_{i}\right\}} \simeq \mathbb{R}^{m_{i}} .
$$

Note that $\varphi_{i}$ expresses $\psi_{i}$ in the affine chart
$\mathbb{P}\left(\mathbb{R}^{A_{i}}\right)_{y_{i v_{i}} \neq 0} \rightarrow \mathbb{R}^{a_{i} \in A_{i} \backslash\left\{v_{i}\right\}},\left[y_{i a_{i}}\right]_{a_{i} \in A_{i}} \mapsto \frac{1}{y_{i v_{i}}}\left(y_{i a_{i}}\right)_{a_{i} \in A_{i} \backslash\left\{v_{i}\right\}}$.
So we are in the setting of Subsection 3.2 and $\varphi_{i}$ is an instance of (3.8). The rows of the matrix $M(x):=D_{x} \varphi$ are labeled by the disjoint union $A_{1} \sqcup \ldots \sqcup A_{n}$ and $M(x)$ has $n$ columns. For any $n$-tuple $\left(a_{1}, \ldots, a_{n}\right)$ with $a_{i} \in A_{i} \backslash\left\{v_{i}\right\}$, we denote by $M(x)_{a_{1}, \ldots, a_{n}}$ the $n \times n$ submatrix of $M(x)$, obtained by selecting from $M(x)$ the rows numbered by $a_{1}, \ldots, a_{n}$. We apply Lemma 3.5 to bound

$$
\begin{aligned}
& \rho_{m_{1}} \cdots \rho_{m_{n}} \int_{C_{v}} x_{1} \cdots x_{n}\left(\bar{\sigma}_{Z} \circ \psi\right) J \psi d w \\
& \quad \leq \sum_{a_{1}, \ldots, a_{n}} \int_{C_{v}} x_{1} \cdots x_{n}\left|\operatorname{det} M(x)_{a_{1}, \ldots, a_{n}}\right| d w,
\end{aligned}
$$

where the sum runs over all tuples $\left(a_{1}, \ldots, a_{n}\right)$ with $a_{i} \in$ $A_{i} \backslash\left\{v_{i}\right\}$. So there are $m_{1} \cdots m_{n}$ many summands. To prove Theorem 1.1, it is sufficient to show that

$$
\begin{equation*}
\int_{C_{v}} x_{1} \cdots x_{n}\left|\operatorname{det} M(x)_{a_{1}, \ldots, a_{n}}\right| d w \leq 1 \tag{4.9}
\end{equation*}
$$

for each vertex $v$ and each selection $\left(a_{1}, \ldots, a_{n}\right)$.
The component (row) of the derivative $D_{x} \varphi_{i}$ corresponding to $a_{i} \in A_{i} \backslash\left\{v_{i}\right\}$ is given by

$$
\left(D_{x} \varphi_{i}\right)_{a_{i}}=x^{a_{i}-v_{i}}\left(a_{i}-v_{i}\right) \operatorname{diag}\left(x_{1}^{-1}, \ldots, x_{n}^{-1}\right)
$$

Hence the $n \times n$-submatrix $M(x)_{a_{1}, \ldots, a_{n}}$ of $M(x)$ is given by

$$
\begin{aligned}
& M(x)_{a_{1}, \ldots, a_{n}}= \\
& \quad \operatorname{diag}\left(x^{a_{1}-v_{1}}, \ldots, x^{a_{n}-v_{n}}\right)\left[\begin{array}{c}
a_{1}-v_{1} \\
\vdots \\
a_{n}-v_{n}
\end{array}\right] \operatorname{diag}\left(x_{1}^{-1}, \ldots, x_{n}^{-1}\right) .
\end{aligned}
$$

Therefore, setting $b_{i}:=a_{i}-v_{i}$, we get

$$
x_{1} \cdots x_{n} \operatorname{det}\left(M(x)_{a_{1}, \ldots, a_{n}}\right)=x^{b_{1}+\ldots+b_{n}} \operatorname{det}\left[b_{1}, \ldots, b_{n}\right]
$$

Let us write $\Pi_{i}$ for the cone of $P_{i}$ at the vertex $v_{i}$. By definition, $b_{i} \in \Pi_{i}^{*}$. By Lemma 2.5, $\Pi:=\Pi_{1}+\ldots+\Pi_{n}$ equals
the cone of the polytope $P=P_{1}+\ldots+P_{n}$ at the vertex $v=v_{1}+\ldots+v_{n}$. Hence $b_{i} \in \Pi_{i}^{*} \subseteq \Pi_{1}^{*} \cap \ldots \cap \Pi_{n}^{*}=\Pi^{*}=C_{v}$.

We can therefore rewrite the left-hand side of (4.9) as

$$
\begin{align*}
& \int_{C_{v}} x_{1} \cdots x_{n}\left|\operatorname{det} M(x)_{a_{1}, \ldots, a_{n}}\right| d w \\
= & \int_{C_{v}} e^{-\left\langle b_{1}+\ldots+b_{n}, w\right\rangle}\left|\operatorname{det}\left[b_{1}, \ldots, b_{n}\right]\right| d w . \tag{4.10}
\end{align*}
$$

By Proposition 2.4, this is at most 1 . This shows claim (4.9) and finishes the proof of Theorem 1.1.

### 4.2 Proof of Proposition 1.2

For finite $S_{i} \subseteq \mathbb{R}$, put $A:=S_{1} \times \ldots \times S_{n}$, and consider

$$
\begin{align*}
& \psi_{i}: \mathbb{R}_{>0} \\
& \psi: \mathbb{P}\left(\mathbb{R}^{S_{i}}\right), x_{i} \mapsto\left[x_{i}^{a_{i}}\right]_{a_{i} \in S_{i}},  \tag{4.11}\\
& \psi: \mathbb{R}_{>0}^{n} \rightarrow \mathbb{P}\left(\mathbb{R}^{A}\right), x \mapsto\left[x^{a}\right]_{a \in A}
\end{align*}
$$

with images $Z_{i}$ and $Z$, respectively. The kinematic formula for real projective space [9, Cor. A.3] gives

$$
\mathbb{E}\left(S_{i}\right)=\frac{\operatorname{vol}\left(Z_{i}\right)}{\operatorname{vol}\left(\mathbb{P}^{1}\right)}, \quad \mathbb{E}(A, \ldots, A)=\frac{\operatorname{vol}(Z)}{\operatorname{vol}\left(\mathbb{P}^{n}\right)}
$$

The key insight is that $Z$ is obtained as the image of $Z_{1} \times$ $\ldots \times Z_{n}$ under the Segre embedding

$$
\mathbb{P}\left(\mathbb{R}^{S_{1}}\right) \times \ldots \times \mathbb{P}\left(\mathbb{R}^{S_{n}}\right) \rightarrow \mathbb{P}\left(\mathbb{R}^{S_{1}} \otimes \ldots \otimes \mathbb{R}^{S_{n}}\right) \simeq \mathbb{P}\left(\mathbb{R}^{A}\right)
$$

which is isometric (see Appendix C). Therefore, we have $\operatorname{vol}(Z)=\operatorname{vol}\left(Z_{1}\right) \cdots \operatorname{vol}\left(Z_{n}\right)$, which completes the proof of Proposition 1.2.

### 4.3 Proof of Proposition 1.3

Given is a finite subset $A \subseteq \mathbb{R}^{n}$ with convex hull $P$. By Lemma 4.2 we can can w.l.o.g. assume that $\operatorname{dim} P=n$. Consider the injective map

$$
\begin{equation*}
\psi: \mathbb{R}_{>0}^{n} \rightarrow \mathbb{P}\left(\mathbb{R}^{A}\right), \psi(x):=\left[x^{a}\right]_{a \in A} \tag{4.12}
\end{equation*}
$$

with image $Z \subseteq \mathbb{P}\left(\mathbb{R}^{A}\right)$. The kinematic formula for real projective space [9, Cor. A.3] is considerably simpler than the one in Theorem 3.2, since $O(m)$ acts transitively on the Grassmann manifolds $\operatorname{Gr}\left(k, \mathbb{R}^{m}\right)$ : we have

$$
\begin{equation*}
\mathbb{E}(A, \ldots, A)=\frac{\operatorname{vol}(Z)}{\operatorname{vol}\left(\mathbb{P}^{n}\right)}=\frac{1}{\operatorname{vol}\left(\mathbb{P}^{n}\right)} \int_{\mathbb{R}_{>0}^{n}} J \psi(x) d x \tag{4.13}
\end{equation*}
$$

We now proceed as in the proof of Theorem 1.1. We make the coordinate change $x=e^{-w}$ and decompose the resulting integral according to the decomposition (4.8) of $\mathbb{R}^{n}$ into the full dimensional cones $C_{v}$ corresponding to vertices $v$. Thus

$$
\begin{aligned}
& \int_{\mathbb{R}_{>0}^{n}} J \psi(x) d x=\int_{\mathbb{R}^{n}} x_{1} \cdots x_{n} J \psi(x) d w \\
& \quad=\sum_{C_{v}} \int_{C_{v}} x_{1} \cdots x_{n} J \psi(x) d w
\end{aligned}
$$

For a fixed vertex $v$ of $P$, we consider the map $\varphi: \mathbb{R}_{>0}^{n} \rightarrow$ $\mathbb{R}^{A \backslash\{v\}}$ defined by

$$
\begin{equation*}
\varphi(x)=\left(x^{a-v}\right)_{a \in A \backslash\{v\}} . \tag{4.14}
\end{equation*}
$$

Then we have $\psi(x)=\pi(\varphi(x))$, where $\pi$ is the inverse of the chart $\mathbb{P}\left(\mathbb{R}^{A}\right)_{y_{v} \neq 0} \rightarrow \mathbb{R}^{A \backslash\{v\}}$. It is easy to verify that $J \psi(x) \leq$ $J \varphi(x)$ using $\left\|D_{\varphi(x)} \pi\right\| \leq 1$, see (2.1).

Le us view $\mathcal{M}(x):=D_{x} \varphi$ as a matrix whose rows are labelled by elements of $A \backslash\{v\}$. and denote by $\mathcal{M}(x)_{a_{1}, \ldots, a_{n}}$ the submatrix of $\mathcal{M}(x)$ obtained by selecting the rows labelled by the $a_{i}$. Cauchy-Binet implies that

$$
J \varphi(x)^{2}=\operatorname{det}\left(\mathcal{M}(x)^{T} \mathcal{M}(x)\right)=\sum_{a_{1}, \ldots, a_{n}}\left(\operatorname{det} \mathcal{M}(x)_{a_{1}, \ldots, a_{n}}\right)^{2}
$$

with the sum running over all $n$-element subsets $\left\{a_{1}, \ldots, a_{n}\right\}$ of $A \backslash\{v\}$, of which there are $\binom{t-1}{n}$ many. This implies $J \varphi(x) \leq$ $\sum_{a_{1}, \ldots, a_{n}}\left|\operatorname{det} \mathcal{M}(x)_{a_{1}, \ldots, a_{n}}\right|$. We have arrived at

$$
\begin{aligned}
& \int_{C_{v}} x_{1} \cdots x_{n} J \psi(x) d w \\
& \left.\quad \leq \sum_{a_{1}, \ldots, a_{n}} \int_{C_{v}} x_{1} \cdots x_{n}\left|\operatorname{det} \mathcal{M}(x)_{a_{1}, \ldots, a_{n}}\right| d w \leq \begin{array}{c}
t-1 \\
n
\end{array}\right)
\end{aligned}
$$

where the right-hand inequality follows from Proposition 2.4 as in (4.10).

### 4.4 Proof of Theorem 1.5

The key observation is the following. Define for $\varepsilon>0$

$$
D_{\varepsilon}:=\left\{x \in \mathbb{R}^{n} \mid\|x\| \geq \varepsilon\right\}
$$

Lemma 4.3. Let $C \subseteq \mathbb{R}^{n}$ be a proper cone, $d \in \operatorname{int}\left(C^{*}\right)$, and $\varepsilon>0$. Then

$$
\lim _{m \rightarrow \infty} m^{n} \int_{C \cap D_{\varepsilon}} e^{-m\langle d, w\rangle} d w=0
$$

Proof. Since $\cap_{m \geq 1} D_{m \varepsilon}=\varnothing$, basic integration theory implies

$$
\lim _{m \rightarrow \infty} \int_{C \cap D_{m \varepsilon}} e^{-\langle d, u\rangle} d u=0
$$

Making the change of variables $u=m w$ shows the claim.

We now observe the following. Let $U \subseteq \mathbb{R}_{>0}^{n}$ be open. Analogously as for (4.6), one shows that

$$
(2 \pi)^{-\frac{n}{2}} \rho_{m_{1}} \cdots \rho_{m_{n}} \int_{U} x_{1} \cdots x_{n}\left(\bar{\sigma}_{Z} \circ \psi\right) J \psi d w .
$$

equals the expected number of nondegenerate zeros in $U$ of the random system (4.3).

We follow the proof of Theorem 1.1. Note that stretching the support does not change the Newton polytopes $P_{i}$ and $P=P_{1}+\ldots+P_{n}$. Fix a vertex $v$ of $P$. According to Lemma 2.5, there are vertices $v_{i}$ of $P_{i}$, for $i=1, \ldots, n$, satisfying $v=$ $v_{1}+\ldots+v_{n}$. Tracing the proof of Theorem 1.1, one sees that it is sufficient to show that (compare (4.10)) for any selection $a_{1} \in A_{1} \backslash\left\{v_{1}\right\}, \ldots, a_{n} \in A_{n} \backslash\left\{v_{n}\right\}$, the vectors $b_{i}=a_{i}-v_{i}$ satisfy

$$
\lim _{m \rightarrow \infty} \int_{C_{v}} e^{-m\left\langle b_{1}+\ldots+b_{n}, w\right\rangle}\left|\operatorname{det}\left[m b_{1}, \ldots, m b_{n}\right]\right| d w=0
$$

However, this is a consequence of Lemma 4.3.

## Acknowledgments

We thank the referees for their comments, in particular for pointing out an error in the interpretation of the bound in Proposition 1.3. The author is supported by the ERC under the European Union's Horizon 2020 research and innovation programme (grant agreement no. 787840).

## A Proof of Proposition 2.1

Let $v_{1}, \ldots, v_{m}$ be an orthonormal basis of $V^{\perp}$. We decompose $v_{i}=v_{i}^{\prime}+v_{i}^{\prime \prime}$ according to $E=W \oplus W^{\perp}$. Then $p\left(v_{i}\right)=v_{i}^{\prime}$ and $|\operatorname{det} p|=\left\|v_{1}^{\prime} \wedge \ldots \wedge v_{m}^{\prime}\right\|$. If $\omega_{1}, \ldots, \omega_{k}$ denotes an orthonormal basis of $W^{\perp}$, we have

$$
\begin{aligned}
& \sigma\left(V^{\perp}, W^{\perp}\right)=\left\|v_{1} \wedge \ldots \wedge v_{m} \wedge \omega_{1} \wedge \ldots \wedge \omega_{k}\right\| \\
& \quad=\left\|v_{1}^{\prime} \wedge \ldots \wedge v_{m}^{\prime} \wedge \omega_{1} \wedge \ldots \wedge \omega_{k}\right\|=\left\|v_{1}^{\prime} \wedge \ldots \wedge v_{m}^{\prime}\right\|
\end{aligned}
$$

the last equality holding since the span of the $v_{i}^{\prime}$ equals $W$, which is orthogonal to the span of the $w_{j}$, which is $W^{\perp}$. This proves $\sigma\left(V^{\perp}, W^{\perp}\right)=|\operatorname{det} p|$.

For the second assertion, we use that $|\operatorname{det} p|=|\operatorname{det} q|$, where $q: W^{\perp} \rightarrow V$ denotes the restriction of the orthogonal projection $E \rightarrow V$ to $W^{\perp}$, see [7, Lemma 5.4].

## B Proof of Lemma 2.3

We fix $x \in \operatorname{int}\left(C^{*}\right)$. For $t \geq 0$ we define the $n-1$-dimensional slice

$$
C_{t}:=\{y \in C \mid\langle x, y\rangle=t\|x\|\} .
$$

By Fubini, we get

$$
\begin{gathered}
v_{C}(x)=\int_{C} e^{-\langle x, y\rangle} d y=\int_{0}^{\infty} \operatorname{vol}_{n-1}\left(C_{t}\right) e^{-t\|x\|} d t \\
=\operatorname{vol}_{n-1}\left(C_{1}\right) \int_{0}^{\infty} t^{n-1} e^{-t\|x\|} d t
\end{gathered}
$$

Note that

$$
\int_{0}^{\infty} t^{n-1} e^{-t\|x\|} d t=\frac{1}{\|x\|^{n}} \int_{0}^{\infty} s^{n-1} e^{-s} d s=\frac{(n-1)!}{\|x\|^{n}}
$$

Moreover, we have

$$
\begin{aligned}
\operatorname{vol}_{n-1}\left(C_{1}\right) & =n \operatorname{vol}_{n}\{y \in C|\langle x, y\rangle \leq \| x|\} \\
= & n\|x\|^{n} \operatorname{vol}_{n}\{y \in C \mid\langle x, y\rangle \leq 1\} .
\end{aligned}
$$

It follows that

$$
\begin{gathered}
v_{C}(x)=n\|x\|^{n} \operatorname{vol}_{n}\{y \in C \mid\langle x, y\rangle \leq 1\} \frac{(n-1)!}{\|x\|^{n}} \\
=n!\operatorname{vol}_{n}\{y \in C \mid\langle x, y\rangle \leq 1\},
\end{gathered}
$$

completing the proof.

## C The Segre embedding is isometric

Consider the Segre embedding

$$
S: \mathbb{P}\left(\mathbb{R}^{m}\right) \times \mathbb{P}\left(\mathbb{R}^{n}\right) \rightarrow \mathbb{P}\left(\mathbb{R}^{m \times n}\right),([x],[y]) \mapsto\left[x_{i} y_{j}\right]
$$

It is well known that $S$ is a smooth embedding. If we endow the real projective space with the standard Riemannian metric (see § 2.1), then $S$ is isometric. This is also true for the Segre embedding with several factors. We provide the proof for lack of reference.

Proposition C.1. The Segre embedding is isometric.

Proof. For notational simplicity, we restrict ourselves to the case of two factors We need to show that the derivatives of $S$ preserve the inner products. By orthogonal invariance, it suffices to consider the derivative at $\left(\left[e_{0}\right],\left[e_{0}\right]\right)$, which is mapped to $\left[E_{00}\right]$. We can isometrically identify the tangent spaces at these points with $\mathbb{R}^{m-1} \times \mathbb{R}^{n-1}$ and $\mathbb{R}^{m n-1}$, respectively. Then derivative of $S$ at $\left(\left[e_{0}\right],\left[e_{0}\right]\right)$ is given by

$$
\mathbb{R}^{m-1} \times \mathbb{R}^{n-1} \rightarrow \mathbb{R}^{m \times n},(v, w) \mapsto\left[\begin{array}{cc}
0 & w^{T} \\
v & 0
\end{array}\right]
$$

Clearly, this map preserves the inner products.

## D Supplement

It is instructive to see how (4.13) directly follows from the more general kinematic formula in Theorem 3.2. Consider the injective map $\psi$ from (4.12) with image $Z \subseteq \mathbb{P}\left(\mathbb{R}^{A}\right)$. We use $\psi$ to define the map

$$
\begin{equation*}
\psi_{d}: \mathbb{R}_{>0}^{n} \rightarrow\left(\mathbb{P}\left(\mathbb{R}^{A}\right)\right)^{n}, x \mapsto(\psi(x), \ldots, \psi(x)) \tag{D.1}
\end{equation*}
$$

The image $Z_{d}=\{(y, \ldots, y) \mid y \in Z\} \subseteq\left(\mathbb{P}^{m}\right)^{n}$ of $\psi_{d}$ is the diagonal embedding of $Z$ in the product of projective spaces. By Theorem 3.2 and (3.6) we have

$$
\mathbb{E}(A, \ldots, A)=(2 \pi)^{-\frac{n}{2}} \rho_{m}^{n} \int_{\mathbb{R}_{>0}^{n}}\left(\bar{\sigma}_{Z_{d}} \circ \psi_{d}\right) J \psi_{d} d x
$$

Via Lemma D. 1 below, we indeed conclude that

$$
\mathbb{E}(A, \ldots, A)=\frac{1}{\operatorname{vol}\left(\mathbb{P}^{n}\right)} \int_{\mathbb{R}_{>0}^{n}} J \psi d x=\frac{\operatorname{vol}(Z)}{\operatorname{vol}\left(\mathbb{P}^{n}\right)}
$$

which is (4.13).
Lemma D.1. For $x \in \mathbb{R}_{>0}^{n}$ we have

$$
\rho_{m}^{n} \bar{\sigma}_{Z_{d}}\left(\psi_{d}(x)\right) J \psi_{d}(x)=\frac{(2 \pi)^{\frac{n}{2}}}{\operatorname{vol}\left(\mathbb{P}^{n}\right)} J \psi(x)
$$

Proof. Lemma 3.4 applied to the map $\psi_{d}$ from (D.1) gives

$$
\begin{align*}
& \rho_{m}^{n} \bar{\sigma}_{Z_{d}}\left(\psi_{d}(x)\right) J \psi_{d}(x) \\
& \quad=\mathbb{E}_{\lambda_{1}, \ldots, \lambda_{n}}\left\|\left(\lambda_{1} \circ D_{x} \psi\right) \wedge \ldots \wedge\left(\lambda_{n} \circ D_{x} \psi\right)\right\| \tag{D.2}
\end{align*}
$$

where the $\lambda_{i}$ are standard Gaussian linear forms on $T_{\psi(x)} \mathbb{P}^{m}$. Take an isometry $T_{\psi(x)} \mathbb{P}^{m} \simeq \mathbb{R}^{m}$, view $\lambda_{i} \in \mathbb{R}^{m}$ as a vector, and view $\Delta:=D_{x} \psi$ as a matrix in $\mathbb{R}^{m \times n}$. We note that $J \psi(x)=\sqrt{\operatorname{det}\left(\Delta^{T} \Delta\right)}$. The right-hand side of (D.2) can be written as the expectation $\mathbb{E}_{\lambda_{i}}|\operatorname{det} R(x)|$, with the matrix

$$
R(x):=\left[\begin{array}{c}
\lambda_{1}^{T} \circ D_{x} \psi  \tag{D.3}\\
\vdots \\
\lambda_{n}^{T} \circ D_{x} \psi
\end{array}\right]=\left[\begin{array}{c}
\lambda_{1}^{T} \\
\vdots \\
\lambda_{n}^{T}
\end{array}\right] \cdot \Delta .
$$

We thus need to prove that

$$
\begin{equation*}
\mathbb{E}_{\lambda_{i}}|\operatorname{det} R(x)|=\frac{(2 \pi)^{\frac{n}{2}}}{\operatorname{vol}\left(\mathbb{P}^{n}\right)} \sqrt{\operatorname{det}\left(\Delta^{T} \Delta\right)} \tag{D.4}
\end{equation*}
$$

In order to show this, by the singular value decomposition, we may assume that $\Delta=\left[\begin{array}{l}D \\ 0\end{array}\right]$, where $D=\operatorname{diag}\left(\sigma_{1}, \ldots, \sigma_{n}\right)$.

Note that $\sqrt{\operatorname{det}\left(\Delta^{T} \Delta\right)}=\sigma_{1} \cdots \sigma_{n}$. Then (D.3) can be written as $R(x)=\Lambda D$, where $\Lambda \in \mathbb{R}^{n \times n}$ is a standard Gaussian square matrix and we get $\mathbb{E}_{\Lambda}|\operatorname{det}(R(x))|=\sigma_{1} \cdots \sigma_{n} \mathbb{E}_{w}|\operatorname{det} \Lambda|$. It is well known that $\mathbb{E}_{\Lambda}|\operatorname{det} \Lambda|=\rho_{n} \rho_{n-1} \cdots \rho_{1}$, e.g., see
[6, Cor. 4.11]. Moreover, $\rho_{n} \rho_{n-1} \cdots \rho_{1}=\frac{(2 \pi)^{\frac{n}{2}}}{\operatorname{vol}\left(\mathbb{P}^{n}\right)}$, since $\rho_{m}=$ $\sqrt{2 \pi} \frac{\mathrm{vol}\left(\mathbb{P}^{m-1}\right)}{\operatorname{vol}\left(\mathbb{P}^{m}\right)}$ by [6, Lemma 2.25]. We have thus verified (D.4).
