Abstract

We explore the features of non-relativistic quantum tunneling in space fractional quantum mechanics through a family of Cantor potentials. We consider two types of potentials: general Cantor and general Smith-Volterra-Cantor potential. The Cantor potential is an example of fractal potential while the Smith-Volterra-Cantor potential doesn't belong to the category of a fractal system. The present study brings for the first time, the study of quantum tunneling through fractal potential in fractional quantum mechanics. We report several new features of scattering in the domain of space fractional quantum mechanics including the emergence of energy-band like features from these systems and extremely sharp transmission features. Further the scaling relation of the scattering amplitude with wave vector k is presented analytically for both types of potentials.

1 Introduction

Over the last two decades, fractional dynamics have been a diverse area of research. The concept of fractional quantum mechanics was introduced by Laskin in the year 2000 [1,2]. The motivation behind this work was to extend the path integral (PI) formulation of quantum mechanics (QM) [3] to the more broader class of paths. In the PI formulation of QM, the path integrals are taken over Brownian paths which lead to the Schrodinger equation of motion. However, the Brownian paths are the subset of a broader general class of paths known as Levy paths characterized by a Levy index α . For $\alpha = 2$, all Levy paths are Brownian paths. When the PI formulation of QM is extended to Levy paths, one get the fractional Schrodinger equation [1,2] and the associated quantum mechanics is known as space fractional quantum mechanics (SFQM). A time fractional Schrodinger equation together to construct a space-time fractional Schrodinger equation. These generalization of QM may help to describe more extensive phenomena of the microscopic world.

The Levy paths has fractal dimension α . In the case of SFQM, the range of α is $1 < \alpha \leq 2$ [1,2]. The domain of SFQM have grown fast over the last two decades and various applications are discussed by different authors. Some of the notable work are the energy band structure for the periodic potential [6], position-dependent mass fractional Schrodinger equation [7], fractional quantum oscillator [8], nuclear dynamics of the H_2^+ molecular ion [9], propagation dynamics of a light beam [10], spatial soliton propagation [11], solitons in the fractional Schrodinger equation with parity-time-symmetric lattice potential [12], gap solitons [13], Rabi oscillations in a fractional Schrodinger equation in a honeycomb lattice [17], scattering features in non-Hermitian SFQM [18], tunneling time [19, 20] etc. Different methods are used in such studies such as domain decomposition method [21], energy conservative difference scheme [22], conservative finite element method [23], fractional Fan sub-equation method [24], split-step Fourier spectral method [25], transfer-matrix method [26] etc.

The term fractal was first coined by Mandelbrot [27]. Fractals are geometric objects which have self-similarity and homogeneity at all known scales. The geometric structures of fractals at a given scale or stage are obtained through a basic mathematical operation acting on the geometric object known as 'initiator'. The process of mathematical operation is called 'generator' which can be repeated on multiple levels. Through 'generator', a geometrical object with sub-units are created that resembles the structure of the entire object (the initiator) [28]. Due to the fact that the real numbers can be divided arbitrarily, the self-similarity of fractals hold at all scales. Since nature has many fractal structures, regular and irregular fragmented structures can be understood/approximated in the context of fractals [27,29,30]. However, in nature, the self-similarity doesn't hold at all scales

and in general, there exists an upper and lower limit within which the self-similarity applies.

One-dimensional scattering by a Cantor fractal potential is one of the simplest scattering problems of quantum tunneling through fractal system. This problem have been extensively studied in quantum mechanics by using the transfer matrix method to derive various scattering properties [31–41]. The composition properties of the transfer matrix have been used to derive the scattering coefficients and associated properties. In Cantor fractal potential, scattering coefficients have been found to show scaling law and sharp features of resonances k [31, 32, 36–38]. The tunneling amplitude from Cantor potential can also be derived by using the concept of super periodic potential (SPP) [41].

Despite the several advancement in the study of SFQM as well as quantum tunneling from fractal potentials, at present tunneling properties from fractal potentials in SFQM is not yet studied. It is expected that such studies will bring new features of scattering properties in the domain of SFQM ($\alpha < 2$) which are absent in the case of standard QM ($\alpha = 2$). In the present study we mainly focus on the simplest fractal system in one dimension, Cantor fractal along with an another member of Cantor family potential known as Smith-Volterra-Cantor (SVC) potential. The SVC potential is not a fractal potential while the Cantor potential is a fractal. In order to keep the study more general in nature, we consider the general Cantor (GC) and general SVC (GSVC) potential system. These are constructed in such a way that for a given initial length L and height V of the rectangular barrier potential, a fraction of $\frac{1}{3}$ from the middle is removed at every stage G' from the remaining segments for standard Cantor-3 potential. For GC potential (or Cantor- ρ potential), instead of $\frac{1}{3}$, a fraction $\frac{1}{\rho}$ is removed where $\rho > 1$ is a real positive number. Similarly in GSVC potential (or SVC- ρ) potential, a fraction of $\frac{1}{\rho^G}$ is removed from the middle at each stage G instead of $\frac{1}{4G}$ as in case of standard SVC-4 system. Again $\rho \in \mathbb{R}^+$ and $\rho > 1$. A simple observation shows that SVC system doesn't satisfy the criteria for the same 'self-similarity' at each stage G and therefore is not a fractal system.

In an earlier work, we have shown that Cantor-3 and SVC-4 potential system are the special case of SPP [41]. This is also true for Cantor- ρ and SVC- ρ system. SPP concept is the generalization of periodic potential having arbitrary number of internal periodicity [41]. As we have not yet extended the concept of SPP in the domain of SFQM, we use the fundamental principle to derive the expressions for transmission amplitude using transfer matrix approach for both types of potential. We report new features of scattering from these systems in the domain of SFQM. Notable features are emergence of energy band structures from these potentials which are absent in standard QM and extremely sharp transmission resonances. The scaling behavior with wave vector k is also presented analytically. This paper is organized as follows. In section 2, an overview of SFQM is presented. The transfer matrix in SFQM for a localized and repeated potential is discussed in detail in the section 3. In section 4 and 5, we provide a brief review of the symmetric fractal potential of the cantor family and its repeated system. In next section 6, explicit expression of ' ζ_j ' (argument of Chebyshev polynomial of second kind) is expressed in order to get transmission amplitude in SFQM for general SVC and general Cantor potential. Afterward, in section 7, we provide graphically a detailed analysis of the transmission features for both the fractal potential in the domain of SFQM. Finally, at last, in section 8 results and discussion are mentioned.

2 Space fractional Schrodinger equation

When the path integral formulation of quantum mechanics is generalized over Levy flight paths, it results in space fractional quantum mechanics (SFQM). The governing equation for SFQM is the space fractional Schrodinger equation. The form of space fractional Schrodinger equation is given by [1],

$$i\hbar \frac{\partial \psi(x,t)}{\partial t} = H_{\alpha}(x,t)\psi(x,t), \qquad (1)$$

Where, $H_{\alpha}(x,t)$ is the fractional Hamiltonian operator. The Hamiltonian is expressed through the use of Riesz fractional derivative $(-\hbar^2 \Delta)^{\alpha/2}$ as,

$$H_{\alpha}(x,t) = D_{\alpha}(-\hbar^2 \Delta)^{\alpha/2} + V(x,t).$$
⁽²⁾

Here ' α ' is the Levy index and $\Delta = \frac{\partial^2}{\partial x^2}$. In SFQM, the range of α is $1 < \alpha \leq 2$ [2]. D_{α} is a constant, also called as generalized diffusion coefficient and depends upon system characteristics. The Riesz fractional derivative of the wave function $\psi(x,t)$ is defined through the use of Fourier transform of $\psi(x,t)$ as,

$$(-\hbar^2 \Delta)^{\alpha/2} \psi(x,t) = \frac{1}{2\pi\hbar} \int_{-\infty}^{\infty} \tilde{\psi}(p,t) |p|^{\alpha} e^{ipx/\hbar} dp.$$
(3)

The Fourier transform of $\psi(x,t)$ is given by,

$$\tilde{\psi}(p,t) = \int_{-\infty}^{\infty} \psi(x,t) e^{-ipx/\hbar} dx.$$
(4)

and its inverse Fourier transform is,

$$\psi(x,t) = \frac{1}{2\pi\hbar} \int_{-\infty}^{\infty} \tilde{\psi}(p,t) e^{ipx/\hbar} dp.$$
(5)

For the case when potential V(x,t) is time independent i.e., V(x,t) = V(x), we have the time independent fractional Hamiltonian operator $H_{\alpha}(x)$ as,

$$H_{\alpha}(x) = D_{\alpha}(-\hbar^2 \Delta)^{\alpha/2} + V(x).$$
(6)

The time-independent space-fractional Schrodinger equation is,

$$D_{\alpha}(-\hbar^2 \Delta)^{\frac{\alpha}{2}} \psi(x) + V(x)\psi(x) = E\psi(x).$$
(7)

By using the concept of separation of variables, it can be shown that the time independent wave function $\psi(x)$ is related to $\psi(x,t)$ as $\psi(x,t) = \psi(x)e^{-iEt/\hbar}$ where E is the energy of the particle. For a detail discussion on SFQM readers are referred to [42].

In the next section, we briefly discuss the transfer matrix formulation of the tunneling problem in SFQM.

3 Transfer matrix in SFQM

Figure 1: Depiction of the scattering of the quantum wave from an arbitrary potential V(x) in one dimension.

Consider a localized potential V(x) bounded in the region (-a, a) as shown in Fig. 1. The solution of time independent space fractional Schrödinger equation (Eq. 7) in all the three regions x < -a, -a < x < a, and x > a are,

$$\varphi(x) = Ae^{ik_{\alpha}x} + Be^{-ik_{\alpha}x}, \quad x < -a, \tag{8}$$

$$\varphi(x) = \varphi_{ab}(x), \quad -a < x < a, \tag{9}$$

$$\varphi(x) = Ce^{ik_{\alpha}x} + De^{-ik_{\alpha}x}, \quad x > a.$$
(10)

Where,

$$k_{\alpha} = \left(\frac{E}{D_{\alpha}\hbar^{\alpha}}\right)^{1/\alpha} \tag{11}$$

and the coefficients A, B, C, and D are the amplitudes of the waves on either side of the potential V(x). The solution of the space fractional Schrödinger equation provides two

linear equations in terms of the coefficients A, B, C, and D. The two linear equations can be represented in matrix form as,

$$\begin{pmatrix} A(k_{\alpha}) \\ B(k_{\alpha}) \end{pmatrix} = M(k_{\alpha}) \begin{pmatrix} C(k_{\alpha}) \\ D(k_{\alpha}) \end{pmatrix}.$$
 (12)

 $M(k_{\alpha})$ is a 2 × 2 matrix,

$$M(k_{\alpha}) = \begin{pmatrix} M_{11}(k_{\alpha}) & M_{12}(k_{\alpha}) \\ M_{21}(k_{\alpha}) & M_{22}(k_{\alpha}) \end{pmatrix},$$
(13)

which is known as the transfer matrix of the potential V(x). For the case when V(x) is Hermitian, the time invariance property of Eq. 7 leads to

$$M_{11}(k_{\alpha}) = M_{22}(k_{\alpha})^*, \quad M_{21}(k_{\alpha}) = M_{12}(k_{\alpha})^*,$$
(14)

i.e., the diagonal and off-diagonal elements are complex conjugate to each other. The determinant of the transfer matrix is always unity which together with the above property implies $|M_{11}(k_{\alpha})|^2 - |M_{12}(k_{\alpha})|^2 = 1$. If the transfer matrix of a potential V(x) is known then one can obtain the scattering coefficients for the potential V(x) through the following expression,

$$t_l(k_{\alpha}) = t_r(k_{\alpha}) = \frac{1}{M_{22}(k_{\alpha})}, \quad r_l(k_{\alpha}) = -\frac{M_{21}(k_{\alpha})}{M_{22}(k_{\alpha})}, \quad r_r(k_{\alpha}) = \frac{M_{12}(k_{\alpha})}{M_{22}(k_{\alpha})}.$$
 (15)

From the knowledge of the transfer matrix of a single localized potential V(x), one can obtain the transfer matrix of the periodic potential when V(x) is periodically repeated N_1 times [43]. Formulation of the transfer matrix of locally periodic media from the knowledge of the transfer matrix of single 'unit cell' potential V(x) is also applicable in space fractional quantum mechanics [26]. The transfer matrix $M_{N_1}(k_{\alpha})$ for the periodic potential is given by,

$$M_{N_{1}}(k_{\alpha}) = \begin{pmatrix} [M_{11}e^{-ik_{\alpha}s}U_{N_{1}-1}(\zeta_{1}) - U_{N_{1}-2}(\zeta_{1})]e^{ik_{\alpha}N_{1}s} & M_{12}U_{N_{1}-1}(\zeta_{1})e^{-ik_{\alpha}(N_{1}-1)s}\\ M_{12}^{*}U_{N_{1}-1}(\zeta_{1})e^{ik_{\alpha}(N_{1}-1)s} & [M_{11}^{*}e^{ik_{\alpha}s}U_{N_{1}-1}(\zeta_{1}) - U_{N_{1}-2}(\zeta_{1})]e^{-ik_{\alpha}N_{1}s} \end{pmatrix}$$

$$(16)$$

In the above expression, 's' is the separation between the starting points of two consecutive 'unit cell' potentials and $U_N(\zeta_1)$ is the Chebyshev polynomial of the second kind. The argument of Chebyshev polynomial ' ζ_1 ', which is the Bloch phase of the corresponding fully developed periodic system, is computed from the knowledge of the 'unit cell' transfer matrix and the separation 's' as [43],

$$\zeta_1(k_{\alpha}) = \frac{1}{2} \left(M_{11} e^{-ik_{\alpha}s} + M_{22} e^{ik_{\alpha}s} \right).$$
(17)

Using the property $M_{11}(k_{\alpha}) = M_{22}(k_{\alpha})^*$, the above equation can also be written as,

$$\zeta_1(k_{\alpha}) = \operatorname{Re}[M_{22}]\cos(k_{\alpha}s) - \operatorname{Im}[M_{22}]\sin(k_{\alpha}s) = |M_{22}|\cos(\phi + k_{\alpha}s), \quad (18)$$

where ϕ is the argument of M_{22} , i.e., $M_{22} = |M_{22}|e^{i\phi}$. The transmission coefficient for the periodic potential is the inverse of the lower diagonal element of the matrix given by 16. Using the unitary properties of the transfer matrix, the transmission amplitude $T = |t_{l,r}|^2$ can be obtained as [43],

$$T(N_1) = \frac{1}{1 + [|M_{12}|U_{N_1-1}(\zeta_1)]^2}.$$
(19)

A few comments and the associated generalizations are in order. We can write the term $[|M_{12}|U_{N_1-1}(\zeta_1)]^2$ appearing in the above equation as $[|M_{12}|U_{N_1-1}(\zeta_1)]^2 = |M_{12}U_{N_1-1}(\zeta_1)|^2$ = $|(M_{12})_{N_1}|^2$ where $(M_{12})_{N_1}$ is the (1, 2) element of the transfer matrix (TM) given by 16. This can also be read as,

 $|M_{12}$ element of periodic system $TM = |M_{12}$ element of unit cell $TM \times$

 U_{N_1-1} (Bloch phase of the fully developed periodic system). (20)

If we periodically repeat this periodic system N_2 times with a different periodic distance s_2 , then from Eq. 20, the modulus of (1, 2) element, $|(M_{12})_{N_1,N_2}|$ of the transfer matrix of the new periodic system will be given by,

$$|(M_{12})_{N_1,N_2}| = |(M_{12})_{N_1}U_{N_2-1}(\zeta_2)| = |M_{12}U_{N_1-1}(\zeta_1)U_{N_2-1}(\zeta_2)|.$$
(21)

Where ζ_2 is the Bloch phase for the new periodic system. If we periodically repeat the systems with parameters N_i and s_i where i = 1, 2, 3, ..., G which yield $\zeta_1, \zeta_2, ..., \zeta_G$ as the respective Bloch phases, then Eq. 21 easily generalizes to

$$|(M_{12})_{N_1,N_2,N_2,\dots,N_G}| = |M_{12} \prod_{i=1}^G U_{N_i-1}(\zeta_i)|.$$
(22)

The corresponding transmission amplitude can be obtained from

$$T(N_1, N_2, N_3, \dots, N_G) = \frac{1}{1 + |(M_{12})_{N_1, N_2, N_2, \dots, N_G}|^2} = \frac{1}{1 + |M_{12}|^2 \prod_{i=1}^G U_{N_i-1}^2(\zeta_i)}.$$
 (23)

A rigorous proof of Eq. 23 based on the transfer matrix elements for super periodic potential is presented in [41] for the case of standard QM. In particular, when $N_i = 2$, we have $U_{N_i-1}(\zeta_i) = U_1(\zeta_i) = 2\zeta_i$. Substitution of this in Eq. 23 leads to

$$T(2, 2, 2, ..., G \text{ times}) = T_G = \frac{1}{1 + 4^G |M_{12}|^2 \prod_{i=1}^G \zeta_i^2},$$
(24)

and the transfer matrix becomes,

$$M_{N_1=2}(k_{\alpha}) = \begin{pmatrix} 2M_{22}^*\zeta_1 e^{ik_{\alpha}s} - e^{2ik_{\alpha}s} & 2M_{12}\zeta_1 e^{-ik_{\alpha}s} \\ 2M_{12}^*\zeta_1 e^{ik_{\alpha}s} & 2M_{22}\zeta_1 e^{-ik_{\alpha}s} - e^{-2ik_{\alpha}s} \end{pmatrix}.$$
 (25)

It is to be noted that the form of Eq. 24 is the general expression for tunneling amplitude when a single potential cell is repeated only two times and that system as a whole is further repeated two times and so on. We will extensively use Eq. 24 and Eq. 25 to calculate tunneling amplitudes for the symmetric potential of Cantor family. It turns out that tunneling amplitude for any symmetric potential which is generated by the division of a real line in three parts and subsequent removal of the middle segment can be expressed using Eq. 24. We will discuss this in detail in the subsequent sections.

4 Symmetric potential of Cantor family

In one dimension, a fractal is generated by the division of a real line in a fashion which preserves self-similarity. Similarly, a rectangular fractal potential can be generated by dividing the length of the barrier in a self-similar fashion while keeping the height of the barrier unchanged. Symmetric fractal potential obeys parity symmetry about the origin i.e., the fractal potential is symmetric with respect to changing $x \to -x$ and $-x \to x$. A potential of Cantor family is generated when the line segments are divided into three parts and the middle parts are removed at any stage G. A particular case of the symmetric Cantor potential is when the removal of the middle part from the line segment leaves the resultant two segments of equal sizes. This configuration of the system is always symmetric. Starting from a length L and stage G = 0, symmetric Cantor potential can be generated by the removal of a fraction $\frac{1}{\rho^{a_1+a_2G}}$ from the middle segment(s) at each stage G. Here $\rho \in \mathbb{R}^+$ and $a_1, a_2 \in \{0, \mathbb{R}^+\}$. When $a_1 = 1$ and $a_2 = 0$, we have general Cantor potential (also, for $a_2 = 0$, a_1 can be absorbed by defining $\rho^{a_1} = \rho_1$ for some real ρ_1 and we still have general Cantor potential). Similarly, for $a_1 = 0$, we have general Smith-Volterra-Cantor (SVC) potential. For the special case when $a_1 = 0$, $a_2 = 1$ and $\rho = 4$ we have standard SVC potential system. Again when $a_1 = 0$, we can absorb a_2 by defining an associated new ρ and the fractal potential is named an SVC- ρ system. The geometrical construction of general Cantor and general SVC potential is illustrated in Fig. 2. At any stage G, both general Cantor and general SVC potential have 2^G segments of equal length l_G . The value of l_G are different for both types of potential. In the case of general Cantor,

$$l_G = \left(\frac{\rho - 1}{2\rho}\right)^G L. \tag{26}$$

For the case of general SVC, l_G can be obtained through the use of the q-Pochhammer symbol as shown below. From Fig. 2, it is noted that,

$$l_1 = \frac{L}{2} \left(1 - \frac{1}{\rho} \right). \tag{27}$$

Similarly, the segment length l_2 for stage G = 2 is,

$$l_2 = \frac{l_1}{2} \left(1 - \frac{1}{\rho^2} \right) = \frac{L}{2^2} \left(1 - \frac{1}{\rho} \right) \left(1 - \frac{1}{\rho^2} \right).$$
(28)

Similarly,

$$l_{3} = \frac{l_{2}}{2} \left(1 - \frac{1}{\rho^{3}} \right) = \frac{L}{2^{3}} \left(1 - \frac{1}{\rho} \right) \left(1 - \frac{1}{\rho^{2}} \right) \left(1 - \frac{1}{\rho^{3}} \right).$$
(29)

Figure 2: Construction of Cantor- ρ and SVC- ρ potential. The white region shows the gap between the potentials and the height of the opaque region is the potential height V. Here G represents the stage of the system. In Cantor- ρ potential, a fraction $1/\rho$ is removed at every stage while in SVC- ρ , a fraction $\frac{1}{\rho^G}$ is removed at each stage G.

By continuing the same steps, the segment length l_G for arbitrary G^{th} order SVC- ρ 0 potential is obtained as,

$$l_{G} = \frac{L}{2^{G}} \prod_{i=1}^{G} \left(1 - \frac{1}{\rho^{i}} \right).$$
 (30)

The product series can be recognized as,

$$\prod_{i=1}^{G} \left(1 - \frac{1}{\rho^i} \right) = q \left(\frac{1}{\rho}; \frac{1}{\rho} \right)_G.$$
(31)

Where,

$$q(a;\lambda)_n = \prod_{i=0}^{n-1} (1-a.\lambda^i) = (1-a)(1-a.\lambda)(1-a.\lambda^2)....(1-a.\lambda^{n-1})$$
(32)

is q-Pochhammer symbol [44]. Therefore, through the use of the q-Pochhammer symbol, we can express l_G as,

$$l_G = \frac{L}{2^G} q \left(\frac{1}{\rho}; \frac{1}{\rho}\right)_G.$$
(33)

5 Symmetric Cantor family potentials as repeating systems

In this section, we illustrate that a symmetric potential of the Cantor family can be generated through a 'unit cell' by repeating it two times and then repeating the resultant 'cell' further two times and so on. Consider a rectangular barrier of height V and width l_G as shown in Fig. 3. We can repeat this barrier at a distance $s_1 > l_G$ as shown in Fig. 3. The resultant system of these two barriers are further repeated at a distance of s_2 thereby generating a system of four rectangular barriers which as a whole is further repeated at a distance of s_3 as shown in Fig. 3. This process of repeating the resultant barrier systems two times at a specific distance can continue up-to an arbitrary stage G. As the Cantor family systems are well defined mathematical structures, the value of ' l_G ' and various ' s_i ' can be easily identified for any arbitrary stage G for a particular system.

Figure 3: Construction of the symmetric Cantor family potential for the stage G = 4 as periodic repetition of the periodic system of order 4.

First we present general expression of s_j for Cantor- ρ fractal system. For this system we have,

$$s_{1} = l_{G} + \frac{l_{G-1}}{\rho},$$

$$s_{2} = l_{G-1} + \frac{l_{G-2}}{\rho},$$

$$s_{3} = l_{G-2} + \frac{l_{G-3}}{\rho},$$

The above sequences show that,

$$s_j = l_{G+1-j} + \frac{l_{G-j}}{\rho}.$$
 (34)

Using Eq. 26, this can be simplified to,

$$s_j = x^{G-j} y L, (35)$$

where,

$$x = \frac{\rho - 1}{2\rho}, y = \frac{\rho + 1}{2\rho}.$$
(36)

Similarly, it can be shown that for SVC- ρ potential, s_j is given by,

$$s_j = l_{G+1-p} + \frac{l_{G-p}}{\rho^{G+1-p}}.$$
(37)

Using Eq. 30 in the above expression, we have after simplification

$$s_j = \frac{L}{2^{G+1-j}} \left(1 + \frac{1}{\rho^{G+1-j}} \right) q \left(\frac{1}{\rho}; \frac{1}{\rho} \right)_{G-j}.$$
 (38)

For a given G, by choosing a single barrier of length l_G as given by Eq. 26 and placing the barrier at various s_j as given by Eq. 35, we get Cantor- ρ potential. Similarly, by choosing l_G from Eq. 33 and s_j from Eq. 38 we get SVC- ρ potential. In the next section, we calculate the transmission amplitudes from these two types of fractal potentials in SFQM.

6 Transmission amplitudes in SFQM

It is clear from the discussion in the previous section that (symmetric) Cantor- ρ (GC) and SVC- ρ (GSVC) potentials are the special cases of systems that are repeated two times and that configuration as a whole is further repeated two times and so on. The number of such operations of repetitions is equal to the stage G of the GC and GSVC potential. The general expression of the tunneling amplitude for such a potential system in SFQM is given by Eq. 24. What remains is to calculate the general expressions for ζ_i , i = 1, 2, 3, ..., G for GC and GSVC potentials. We will derive the general expression for ζ_i and then would specialize to calculate specific expressions for ζ_i for GC and GSVC potentials. The calculations are illustrated below. Let $M_{22}(k_{\alpha})$ denotes the lower diagonal elements of the transfer matrix of rectangular barrier of width $b = l_G$ and height V. This potential configuration is represented by P_0 in the Fig. 3. Similarly, let $(M_{22})_1$, $(M_{22})_2$, $(M_{22})_3$ etc. denote the lower diagonal elements of the transfer matrix of the combined system represented by P_1 , P_2 , P_3 etc. as shown in Fig. 3. The corresponding Bloch phases are ζ_1 , ζ_2 , ζ_3 etc. respectively. From Eq. 25 we can read that

$$(M_{22})_j = 2(M_{22})_{j-1}\zeta_j e^{-ik_\alpha s_j} - e^{-2ik_\alpha s_j},$$
(39)

where j = 1, 2, 3, ..., G and $(M_{22})_0 = M_{22}$. Now from the general Eq. 18 we can write,

$$\zeta_2(k_\alpha) = \operatorname{Re}[(M_{22})_1] \cos k_\alpha s_2 - \operatorname{Im}[(M_{22})_1] \sin k_\alpha s_2.$$
(40)

We can use Eq. 39 in the above equation so that,

$$\zeta_2(k_\alpha) = \operatorname{Re}[(2 \times M_{22}.\zeta_1)e^{-ik_\alpha s_1} - e^{-2.ik_\alpha s_1}]\cos k_\alpha s_2 - \operatorname{Im}[(2 \times M_{22}\zeta_1)e^{-ik_\alpha s_1} - e^{-2.ik_\alpha s_1}]\sin k_\alpha s_2. \quad (41)$$

The simplification of the real and imaginary parts finally gives,

$$\zeta_2 = 2|M_{22}|\zeta_1 \cos\left[\phi - k_\alpha \{s_1 - s_2\}\right] - \cos\left[k_\alpha \{2s_1 - s_2\}\right].$$
(42)

Similarly, repeating the above procedure to calculate ζ_3 we have,

$$\zeta_3 = \operatorname{Re}[(M_{22})_2] \cos k_\alpha s_3 - \operatorname{Im}[(M_{22})_2] \sin k_\alpha s_3.$$
(43)

Again using Eq. 39 to simplify the above, we obtain for ζ_3 ,

$$\zeta_{3}(k_{\alpha}) = 2^{2} |M_{22}| \zeta_{1} \zeta_{2} \cos \left[\phi - k_{\alpha} \{s_{1} + s_{2} - s_{3}\}\right] - 2.\zeta_{2} \cos \left[k_{\alpha} \{2s_{1} + s_{2} - s_{3}\}\right] - \cos \left[k_{\alpha} \{2s_{2} - s_{3}\}\right].$$
(44)

Similarly, we have for ζ_4

$$\zeta_4(k_\alpha) = \operatorname{Re}[(M_{22})_3] \cos k_\alpha s_4 - \operatorname{Im}[(M_{22})_3] \sin k_\alpha s_4.$$
(45)

The repeated application of Eq. 39 and simplifications of the real and imaginary parts in the above equation gives,

$$\zeta_4(k_\alpha) = 2^3 |M_{22}| \zeta_1 \zeta_2 \zeta_3 \cos \left[\phi - k_\alpha \{ s_1 + s_2 + s_3 - s_4 \} \right] - 2^2 \zeta_2 \zeta_3 \cos \left[k_\alpha \{ 2s_1 + s_2 + s_3 - s_4 \} \right] - 2.\zeta_3 \cos \left[k_\alpha \{ 2s_2 + s_3 - s_4 \} \right] - \cos \left[k_\alpha \{ 2s_3 - s_4 \} \right].$$
(46)

Similarly, the expression for ζ_5 is given by,

$$\zeta_{5}(k_{\alpha}) = 2^{4} |M_{22}| \zeta_{1} \zeta_{2} \zeta_{3} \zeta_{4} \cos \left[\phi - k_{\alpha} \{s_{1} + s_{2} + s_{3} + s_{4} - s_{5}\}\right] - 2^{3} \zeta_{2} \zeta_{3} \zeta_{4} \cos \left[k_{\alpha} \{2s_{1} + s_{2} + s_{3} + s_{4} - s_{5}\}\right] - 2^{2} \zeta_{3} \zeta_{4} \cos \left[k_{\alpha} \{2s_{2} + s_{3} + s_{4} - s_{5}\}\right] - 2.\zeta_{4} \cos \left[k_{\alpha} \{2s_{3} + s_{4} - s_{5}\}\right] - \cos \left[k_{\alpha} \{2s_{4} - s_{5}\}\right].$$
(47)

We observe from the sequence of Eqs. 42, 44, 46, and 47 that the general expression for ζ_j can be written in the following series form,

$$\zeta_j(k_\alpha) = 2^{j-1} |M_{22}| \cos\left[\phi - k_\alpha \eta_1(j)\right] \prod_{p=1}^{j-1} \zeta_p - \sum_{r=1}^{j-1} \left[2^{j-r-1} \cos\left[k_\alpha \eta_2(j,r)\right] \prod_{p=r+1}^{j-1} \zeta_p \right].$$
(48)

In the above equation, we have used the following notation,

$$\eta_1(j) \equiv \left(\sum_{p=1}^{j-1} s_p\right) - s_j,\tag{49}$$

$$\eta_2(j,r) \equiv \left(\sum_{p=r}^j s_p\right) - (2s_j - s_r).$$
(50)

It is easy to show that,

$$\eta_2(j,r) \equiv \eta_1(j) - \eta_1(r).$$
 (51)

Eq. 48 is the general expression for ζ_j , j = 1, 2, 3, ..., G. However, it is important to note here that in Eq. 48, we have to drop the terms when the running variable 'r' is more than the upper limit for the summation operation and we take terms as unity when the running variable is more than the upper limit for the product operation. From the knowledge of $\zeta_1, \zeta_2, \zeta_3, ..., \zeta_G$, we can calculate the tunneling amplitude from Eq. 24. Now we calculate the values of $\eta_{1,2}$ and their properties.

Figure 4: Symmetric Cantor family potential shows the length and gap between the segments.

From Fig. 3 and 4, we observe $s_1 = l_G + g_G$, $s_2 = s_1 + l_G + g_{G-1}$, $s_3 = s_1 + s_2 + l_G + g_{G-2}$,

 $s_4 = s_1 + s_2 + s_3 + l_G + g_{G-3}$ and so on. Thus we arrive at,

$$s_j = \left(\sum_{p=1}^{j-1} s_p\right) + l_G + g_{G-j+1}.$$
 (52)

Therefore, $\eta_1(j)$ is given by,

$$\eta_1(j) = -(l_G + g_{G-j+1}), \tag{53}$$

which shows that $\eta_1(j)$ is always negative. Combining Eq. 51 and 53 we get,

$$\eta_2(j,r) = g_{G-r+1} - g_{G-j+1}.$$
(54)

We see from Fig. 4 that for i > j, $g_i < g_j$. Also for r < j, G - r + 1 > G - j + 1 which implies $g_{G-r+1} < g_{G-j+1}$. Therefore $\eta_2(j,r) < 0$ for r < j. Eq. 53 and 54 gives the general expression for η_1 and η_2 respectively. Now we provide these expressions for GC and GSVC cases.

6.1 Case 1: General SVC potential

To calculate $\eta_{1,2}$ for GSVC, we re-write Eq. 33 as

$$l_{j-1} = \frac{L}{2^{j-1}} q\left(\frac{1}{\rho}; \frac{1}{\rho}\right)_{j-1}.$$
(55)

As we know, for GSVC a fraction $\frac{1}{\rho^{j}}$ is removed from segment length l_{j-1} to generate the system for stage G = j, therefore, $g_{j} = \frac{l_{j-1}}{\rho^{j}}$ and hence,

$$g_j = \frac{L}{\rho^j 2^{j-1}} q\left(\frac{1}{\rho}; \frac{1}{\rho}\right)_{j-1}.$$
(56)

Now we simplify for $\eta_1(j)$ by using Eq. 53, Eq. 33 and Eq. 56 to obtain,

$$\eta_1(j) = -\left\{ \frac{L}{2^G} q\left(\frac{1}{\rho}; \frac{1}{\rho}\right)_G + \frac{L}{2^{G-j}} q\left(\frac{1}{\rho}; \frac{1}{\rho}\right)_{G-j} \frac{1}{\rho^{G-j+1}} \right\}.$$
(57)

Now we calculate $\eta_2(j, r)$ by using Eq. 51 and 57 to obtain,

$$\eta_2(j,r) = \frac{2L}{(2\rho)^{G+1}} \left\{ (2\rho)^r q\left(\frac{1}{\rho};\frac{1}{\rho}\right)_{G-r} - (2\rho)^j q\left(\frac{1}{\rho};\frac{1}{\rho}\right)_{G-j} \right\}$$
(58)

Now we can substitute Eq. 57 and 58 in Eq. 48 to obtain the general expression for ζ_j for GSVC potential.

6.2 Case 2: General Cantor potential

We re-write Eq. 26 as,

$$l_{j-1} = \left(\frac{\rho - 1}{2\rho}\right)^{j-1} L.$$
(59)

As we know, in case of GC potential, a fraction $\frac{1}{\rho}$ is taken from stage G = j - 1 to create the fractal system for G = j stage, therefore $g_j = \frac{l_{j-1}}{\rho}$ and thus,

$$g_j = \frac{1}{\rho} \left(\frac{\rho - 1}{2\rho}\right)^{j-1} L.$$
(60)

Now, using Eq. 53 and 26 in Eq. 60, we simplify for $\eta_1(j)$ to get,

$$\eta_1(j) = -\left\{ L. \left(\frac{\rho - 1}{2\rho}\right)^G + \frac{L}{\rho}. \left(\frac{\rho - 1}{2\rho}\right)^{G-j} \right\}.$$
(61)

Now using Eq. 51, $\eta_2(j, r)$ can be simplified as,

$$\eta_2(j,r) = \frac{L}{\rho} \left(\frac{\rho-1}{2\rho}\right)^{G-r-j} \left\{ \left(\frac{\rho-1}{2\rho}\right)^j - \left(\frac{\rho-1}{2\rho}\right)^r \right\}.$$
(62)

Substitution of Eq. 61 and 62 in Eq. 48 gives the general expression of ζ_j for GC potential.

7 Transmission features

In the previous section, the analytical expressions of the tunneling amplitudes from two types of Cantor potentials in SFQM have been derived. In this section, we study the various features of transmission through these systems in SFQM. As the Cantor potentials have been studied in detail in standard QM ($\alpha = 2$) [31–41], therefore we largely focus here to study the tunneling behavior in the domain of SFQM (i.e., the case of $\alpha < 2$) as well as the comparison with the case of standard QM (i.e., the case of $\alpha = 2$). Fig. 5 shows the comparison of the profiles of the transmission amplitudes for GC and GSVC potential in standard QM and in SFQM for different stages G. In all plots of Fig. 5, it is noted that the transmission resonances are much sharper in GSVC potential as compared to GC potential. As these two types of potentials are different, they show different transmission profiles which are not relatable (at the present level of investigations) though both are special cases of repeating systems. Therefore, we present these two cases separately in subsequent sections. Subsection 7.1 discusses the case of GSVC while subsection 7.2 details the case for GC potential.

Figure 5: Plots showing the comparison of transmission amplitudes for GC (Red-curve) and GSVC (Blue-curve) potential for two different stages of G (= 3 and 5) in SFQM (α = 2.00, 1.90 and 1.80). Here potential parameters are L = 1, V = 400 and ρ = 3.5. From figures, it is observed that GSVC potential has sharper peaks as compared to general Cantor potential.

7.1 Transmission features of general SVC potential in SFQM

Figure 6: The transmission amplitude for GSVC potential in SFQM with α and k. The potential parameters are V = 100, $\rho = 3$ and G = 3. The transmission peaks occurs at lower k values with decreasing α . It is also evident from Fig. (c) that the sharpness of the transmission peaks are increasing as α is lowered.

This section exclusively discusses the nature of the transmission profile from GSVC system in SFQM. As the expression for the transmission amplitude is transcendental in nature (Eq. 24), presently we rely on the numerical investigation towards investigating the general features of tunneling amplitude. The transmission amplitude is plotted for stage G = 3 in Fig. 6. To understand the behavior of transmission resonances with α , we 3D plot $T(\alpha, k)$ with α and k as shown in Fig. 6-a. Here the potential parameters are $V = 100, \ \rho = 3$, and G = 3. A closer look at this figure is shown in Fig. 6-b for a smaller range of k. From both these figures, it is seen that the locus of transmission resonances has a positive slope with increasing α . This indicates that the transmission peaks are red-shifted with decreasing values of α . This appears to be a general trend for the case when α is not far away from 2. However, much more complex behavior of the locus of transmission resonances is seen when α is closer to 1 and is presented later in the paper. Fig. 6-c shows the 2D plot depicting the variation of T for different α with the same range of k as shown in Fig. 6-b. This figure shows that the transmission resonances become sharper at lower values of α . This appears to be a general feature and will be more evident in the later part of the discussion and associated graphical representations.

Figure 7: Plots showing several sharp transmission resonances near unity (i.e $\alpha = 1$) for GSVC potential of stage G = 5 in SFQM. The potential parameters are V = 450, L = 1 and $\rho = 3$.

An interesting parameter region for the study of tunneling amplitude in SFQM is the case when α is close to 1. In this regime, extreme behavior in the transmission amplitudes is observed which is demonstrated graphically in Fig. 7. The figure shows the transmission amplitude for stages G = 5, V = 450, L = 1, and different values of α near unity. In all these figures, the emergence of several extremely sharp transmission resonances is observed for both evanescent and non-evanescent waves. The transmission resonances are separated by deep valleys in the T(k) profile such that T(k) vanishes over a range of k (it may be noted that for any Hermitian potential, as in the present case transmission amplitudes are never ideally zero [45]). Many transmission resonances in Fig. 7 are extremely sharp and appear as the sudden jump from T = 0 to T = 1. Towards understanding these features over a continuous range of α near 1, the transmission amplitudes are represented through density plots in $\alpha - k$ plane for different stages of the potential in Fig. 8 and Fig. 9. For both these figures L = 1, $\rho = 3$ while V = 300 and 450 for Fig. 8 and Fig. 9 respectively.

Figure 8: Density plot showing the variation of transmission amplitude T in $\alpha - k$ plane for α close to 1 for GSVC potential of different stages G = 5 and 7. The potential parameters are V = 300, L = 1 and $\rho = 3$. Extreme sharp transmission resonances are seen. For both the stages of the potential, extreme behavior of variations in T is observed for wave energy E < V. However, for E > V, the transmission amplitudes are observed to saturate with increasing G. Further, deep minima in T occur in the transmission profile for several finite ranges of k which indicates the presence of allowed and forbidden band-like structures from this potential system in SFQM.

The different stages G are shown in the figures. Both these figures indicate the presence of extremely sharp transmission resonances as thin streaks of yellow lines. In some cases, the lines are so thin that these are not captured graphically over the red regions. The behavior of these T = 1 loci is challenging to understand analytically due to the transcendental nature of the expression of the tunneling amplitudes. Extreme variations for both α and k are observed for wave energy E < V while for E > V the transmission profile appears to saturate with increasing G. An apparent conclusion that may be drawn from Fig. 8 and 9 is the presence of deep valleys in the transmission amplitudes for which T is nearly vanishing in $\alpha - k$ plane for α in the vicinity of 1. The presence of these valleys in the transmission amplitudes is noted as the precursor of the emergence of allowed and forbidden energy bands [46] from locally periodic potential. This shows that the band features emerge in the case of GSVC potential in SFQM. In the case of standard QM, the band doesn't appear from Cantor family potential to the best of our knowledge. However, the emergence of band-like features from GSVC potential (and will be shown later for GC potential) appears only when α is in the vicinity of 1.

Figure 9: Density plot showing the variation of transmission amplitude T in $\alpha - k$ plane for α close to 1 for GSVC potential of different stage G. Here V = 450 and other parameters are the same as Fig. 8. Again, the presence of extremely sharp transmission resonances is noticed with extreme variations in T for wave energy E < V. It is also seen in the figure that the transmission amplitude saturates with increasing G for E > V. Again, the density plot shows the occurrence of band-like features.

A discussion is in order. The deep valleys in T(k) profile for a periodic potential for a range Δk means that the waves are reflected from the potential for $k \in \Delta k$. From the emergence of deep valleys in T for tunneling through locally periodic delta potential, it is argued that the band-like structures emerge even when number of periodic delta barriers are just five, N = 5 [43, 46]. Based on the similar studies in SFQM, it is noted that the band emerges even when N = 4 and are more prominently present for lower α values [26]. In the present case, the repetitions are based on $N_i = 2$. As N = 2 system doesn't show band structure (and deep valleys in T for ranges of k) in standard QM, the type of Cantor family system studied here don't show allowed energy bands in standard QM.

Figure 10: Plot of transmission amplitude for G = 1 (double barrier system), above Fig. (a) shows density plot for potential height V = 500 and Fig. (b) represent 2D plot for potential height V = 648 with potential width L = 1 for both cases. Both these plots show the occurrence of valleys for which T is very close to zero. Fig. (c) shows the density plots for potential parameters V = 700, L = 1 in $\alpha - k$ plane for range of α from 1.001 to 1.01 and Fig. (d) corresponding 2D plot when $\alpha = 1.004$ for same potential parameters as Fig. (c). The density plot clearly shows range of k for which T nearly vanishes. This again indicates the presence of allowed bands for the double barrier system. Interesting oscillations are seen in T over $\alpha - k$ plane for the evanescent waves.

Thus, a question may arise that if the present GSVC system, which is an arrangement of $N_i = 2$ barriers, show band likes features for $\alpha \to 1$, would this also mean that a double barrier system will show energy bands like features for $\alpha \to 1$. Surprisingly, we find that this is indeed the case and are graphically shown in Fig. 10 for three different double barrier potential systems in SFQM. It is an extraordinary fact to recognize that there are allowed and forbidden bands for just double barrier systems in the domain of SFQM. If the N = 2 barriers system could show band structures in SFQM, therefore the present GSVC systems which are $N_i = 2$ repeating systems could also show energy band structures. We will show in the later section that this is also true for GC potential in SFQM for α near to 1.

Figure 11: Plot of $\log_{10} (-\log_{10} T)$ for the case of general SVC and general Cantor potential for G = 7 (red curve), G = 9 (dashed green curve), and G = 11 (dashed blue curve). The potential parameters are V = 100, L = 1 and $\rho = 3$. As it is clearly visible from first column (for general SVC) and second column (for general Cantor), that the tunnelling saturates with increasing G in standard (i.e., $\alpha = 2$) as well as in SFQM for general SVC potential. However, this saturation behavior is not observed for general Cantor potential in SFQM.

Another observation from Fig. 9 is the saturation of the transmission profile with increasing G. From the definitions of GSVC system, a portion $\frac{1}{\rho^G}$ is taken out from the middle at each stage G. Thus progressively lesser fractions are taken from each stage with increasing G. This would imply that for larger G, the transmission profile should saturate with G as only very thin portions are removed from the segments of the previous stages when G is large. This is illustrated graphically in Fig. 11 in which a function of T is plotted for GSVC and GC potential for stages G = 7,9 and 11 for different α . For a better resolution in different T(k, G), we have plotted $y = \log_{10} (-\log_{10} T)$ in y-axis. As $0 < T \leq 1$, therefore $\log_{10} T \leq 0$ and thus $-\log_{10} T \geq 0$. This implies that the function $y = \log_{10} (-\log_{10} T)$ is well defined. Various plots with different α in Fig. 11 show that the saturation in T(k) profile with G is observed in GSVC potential but not in GC potential. However, for $\alpha \to 1$, this saturation is present only in the case for wave energy E > V and not for E < V as shown in Fig. 12 for different potentials and $\alpha = 1.01$.

Figure 12: Plot of $\log_{10}(-\log_{10} T)$ for the case of GSVC for G = 5 (red curve), G = 8 (dashed green curve), and G = 11 (dashed blue curve). The potential parameters are L = 1, $\rho = 3$, and the height V is indicated in each figure. It is seen from all these plots that for values of α close to 1, T(k) profile saturates with G when wave energy $E(=k^2/2m) > V$. No saturation in the T(k) profile is observed when E < V.

7.2 Transmission features of general Cantor potential in SFQM

Figure 13: Plot showing the transmission profile for general Cantor of stage G = 3, $\rho = 3$, L = 1 and V = 100 for different value of α . It is evident from the plots that as α reduces, the transmission peaks shifts to lower values of wave numbers. (Right Image) 3D plot showing the variation of T with α and k which again depict that the transmission peak occurs at lower k values with reducing α .

In the previous section, we provided some general features of scattering such as emergence of energy bands, increase in the sharpness of transmission resonances with reducing α , extreme features of transmission for α near to 1 etc. for GSVC potential, In this section, we show that such features also exists for GC potential in SFQM. In Fig. 13, we plot $T(\alpha, k)$ with α and k with potential parameters as G = 3, V = 100, $\rho = 3$ and L = 1. A closer look of this figure is shown in Fig. 13-b for a smaller range of k. Similar to the case of GSVC for α near 2, it is seen that the locus of transmission resonances has a positive slope with increasing α . This indicates that the transmission peaks are red-shifted with decreasing values of α for GC potential in SFQM. An exception to this could occur when α is in the vicinity of 1 (see Fig. 14). Fig. 13-c shows the 2D plot depicting the variation of T for different α with the same range of k as shown in Fig. 13-b. Again, similar to the case of GSVC potential, it is observed that the transmission resonances become sharper at lower values of α . Fig. 14 also shows extremely sharp loci of transmission resonances as thin streaks of yellow lines.

Figure 14: Density plot showing the variation of transmission amplitude T in $\alpha - k$ plane for α close to 1 for GC potential of different stages G. Here V = 450, L = 1 and $\rho = 3$. Along with the presence of very sharp transmission peaks, the plots also shows the region of deep valleys in $\alpha - k$ plane where transmission amplitude continuously vanishes. These deep valleys in the transmission profile are the precursor of energy band structure.

These lines are also separated by deep valleys in T(k) profile which depict the presence of energy band-like features. The deep valleys in T(k) profiles are also shown graphically in Fig. 15 through the density of $T(\alpha, k)$ in $\alpha - k$ plane as well as 2D plots for discrete values of α . It is to be noted from Fig. 15, that many sharp features of transmission resonances that are not visualized due to graphic limitations of capturing very thin streaks of lines are clearly seen in 2D plots.

Figure 15: (a) Density plot for GC potential of stage G = 4 showing sharp transmission in $\alpha - k$ plane and energy band features when α is close to 1 and (b) more closer view of density plot for α ranging from 1.001 to 1.005. 2D plots illustrate clearly sharp valley for $\alpha = 1.002, 1.003, and 1.004$. Here potential parameters are V = 450, L = 1 and $\rho = 3$.

7.3 Scaling behavior

This section presents the scaling behavior of the reflection amplitudes $R = |r|^2$ with k for both types of Cantor potentials considered in the paper. This section also present on how the reflection amplitude behaves when height of the potential V varies in specific manner at each stage G. For larger k, reflection amplitude R is very small. In this limit, R can be approximated as

$$R \sim 4^G |M_{12}|^2 \prod_{i=1}^G \zeta_i^2.$$
(63)

Again for larger k we have $\frac{V}{k^2} \ll 1$ and upon Taylor expanding, it can be shown in the first order that

$$|M_{12}|^2 \sim \left(\frac{\alpha - 1}{\alpha} V l_G\right)^2 \frac{1}{k^{\frac{4(\alpha - 1)}{\alpha}}}.$$
(64)

Therefore, the expression for R becomes,

$$R \sim 4^G \left(\frac{\alpha - 1}{\alpha} V l_G\right)^2 \frac{1}{k^{\frac{4(\alpha - 1)}{\alpha}}} \prod_{i=1}^G \zeta_i^2.$$
(65)

If V_G is the height of the potential at each stage G, then it can be shown that the following value of V_G keeps the total area of potential barrier (sum of the area of all potential segment at stage G) as constant

$$V_G = \frac{L}{2^G l_G} V_0, \tag{66}$$

where V_0 is the height of the potential barrier at G = 0. Substituting the value of l_G for GC and GSVC potentials, V_G is given by

$$V_G = \left(\frac{\rho}{\rho - 1}\right)^G V_0, \text{ for GC and, } V_G = \frac{V_0}{q\left(\frac{1}{\rho}; \frac{1}{\rho}\right)_G} \text{ for GSVC.}$$
(67)

If R_G is the reflection amplitude at each stage G with potential height of each segment as V_G then, it can be shown that (valid for large k)

$$\frac{R_G}{L^2 V_0^2} \sim \left(\frac{\alpha - 1}{\alpha}\right)^2 \frac{1}{k^{\frac{4(\alpha - 1)}{\alpha}}} \prod_{i=1}^G \zeta_i^2.$$
(68)

Figure 16: Plot showing the reflection amplitudes for GSVC potential for G = 5 and 10. The potential height V_G is determined from Eq. 67 for GSVC potential. Other potential parameters are shown in the figure. The difference between the two plots is invisible. This shows the convergence of the product term of Eq. 68.

In Fig. 16 we show the behavior of R_5^{GSVC} and R_{10}^{GSVC} . The difference between the two plots is invisible which shows the fast convergence of product term of Eq. 68 with

increasing G for GSVC case in SFQM. Similar plots are shown for GC case for different α values in Fig. 17. The result shows that the convergence of the product term occurs for GC case in SFQM with increasing stage G.

Figure 17: Plots showing the reflection amplitudes for GC potential for G = 10 and 15 for different α value. The potential height V_G is determined from Eq. 67 for GC case. Other potential parameters are shown in the figure. The difference between the two plots is nearly invisible. This shows the convergence of product term of Eq. 68 for GC potential.

For Cantor potential in standard QM, this has already shown in earlier work [37]. Again, due to the convergence nature of the product term (provided it is evaluated at V_G) with increasing G, it is evident from Eq. 68 that R_G would scale as $\frac{1}{k^{\frac{4(\alpha-1)}{\alpha}}}$ for large Gand k values. For $\alpha = 2$, R_G will scale as $\frac{1}{k^2}$ which is proven result for standard Cantor potential in standard QM [37]. The scaling behavior of R_G with k in SFQM is shown graphically for GC potential in Fig. 18. An interesting region of interest is when α is near to 1. In this case R_G would scale horizontally with k which is indeed the case as shown in Fig. 18-c. The scaling behavior of R_G with k is shown in Fig. 19 for GSVC potential for different α values.

Figure 18: $\log - \log$ Plots showing the scaling behavior of reflection amplitudes $\frac{R_G}{V_0^2}$ for large k in SFQM in case of general Cantor potential. The dotted curve represent $\frac{1}{k^{\frac{4(\alpha-1)}{\alpha}}}$. It is observed that at large k, R_G falls of according to this expression. The potential parameters are shown in the figures.

Figure 19: Plots shows reflection amplitude $\frac{R_G}{V_0^2}$ for large k in SFQM ($\alpha = 1.90$ and $\alpha = 1.50$) for general SVC potential. The dotted curve represent $\frac{1}{k\frac{4(\alpha-1)}{\alpha}}$. It is observed that at large k, R_G falls of according to this expression. The potential parameters are shown in the figures.

8 Results and Discussions

Fractional quantum mechanics is a fast-developing domain with several applications. We have studied the tunneling features from fractal (general Cantor) and non-fractal (general SVC) potential in space fractional quantum mechanics (SFQM). To the best of our knowledge, this is the first time that the quantum tunneling from fractal potentials in the domain of SFQM are studied. We have considered the generalized form of two kinds of potentials of Cantor family, namely general Cantor (GC) and general Smith-Volterra-Cantor (GSVC) potential. For both the kind of potentials, we have provided close form expressions of transmission amplitudes in SFQM. These close form expressions are expected to provide better understanding of various scattering features in the domain of SFQM from fractal potentials. It is to be noted that the derived expressions are of gen-

eral type and valid for any potentials of GC and GSVC type in which the 'unit cell' is not a rectangular barrier. As long as the transfer matrix of 'unit cell' potential is known, the derived expressions can be used to obtain the tunneling amplitudes from such kind of Cantor family potentials.

In the present study, we have found several new features of scattering, and are reported graphically. The most striking feature is the appearance of energy band structures from fractal potential in SFQM which are absent in the case of standard Cantor fractal and standard SVC potentials in standard QM. Standard fractal potentials based on $\frac{1}{3}$ division of the real segments don't show energy band-like features in standard QM. More surprisingly we noted that a double barrier potential system display energy bands in SFQM. We have reported the emergence of band structures for both the type, GC and GSVC potentials. However, it is to be noted that these band like features appear in the extreme range of Levy index α close to the vicinity of 1. In this range of α , extremely sharp transmission resonances are found to occur for both type of potentials.

Fractal potentials are known to display sharp transmission resonances, This feature is further amplified in the domain of SFQM. It is found that the sharpness of the transmission resonances further increases with a decrease in Levy index α . In comparison, GSVC potential displays more sharp transmission resonances as compared to GC potential in standard QM as well as in SFQM. Also for the case of GSVC potential, it is observed that the profile of transmission amplitudes saturates with increasing stage G. The reason for this is due to the fact that a consecutively smaller fraction of the remaining previous segments is removed at each stage G for GSVC potentials Therefore for higher G, only very thin portions are removed from previous segments as compared to the case when G is small. This leads to the saturation of the tunneling profile with k for higher G. However, this behavior is found to be different near $\alpha = 1$. For $\alpha \sim 1^+$, the tunneling profile saturates only for E > V.

Another interesting feature is the scaling behavior of reflection amplitude. We have shown analytically that for large k, the reflection coefficient scale as $\frac{1}{k^{\frac{4(\alpha-1)}{\alpha}}}$ for GC and GSVC potential provided that total area of the potential regions remain constant at different stages G. Also for such case, the reflection amplitude converges as G increases for both GC and GSVC systems.
