## Abstract

Gender inclusivity in language has become a central topic of debate and research. Its application in the cross-lingual contexts of human and machine translation (MT), however, remains largely unexplored. Here, we discuss Gender-Neutral Translation (GNT) as a form of gender inclusivity in translation and advocate for its adoption for MT models, which have been found to perpetuate gender bias and discrimination. To this aim, we review a selection of relevant institutional guidelines for Gender-Inclusive Language (GIL) to collect and systematize useful strategies of gender neutralization. Then, we discuss GNT and its scenarios of use, devising a list of desiderata. Finally, we identify the main technical challenges to the implementation of GNT in MT. Throughout these contributions we focus on translation from English into Italian, as representative of salient linguistic transfer problems, due to the different rules for gender marking in their grammar.

## 1 Introduction

Gender bias and discrimination perpetuated through language have become prominent topics of discussion, both within and outside the scientific community. Indeed, that language grants the power to reproduce and reinforce societal asymmetries has been long claimed by feminist language critique (Lazar, 2005). Social scientists as well have framed biased communicative practices as a socio-political concern, underscoring how language can reflect

the perceived value, power and status associated with genders in society (Pauwels, 2003), e.g., distinguishing between *Mrs./Miss* for women only. Psycholinguists have investigated the influence of gendered forms on cognition (Boroditsky et al., 2003), proving how masculine generics – i.e., masculine forms, in theory generically intended in reference to mixed groups – actually evoke a male bias (Gygax et al., 2019). Even in the news, gender-related issues appear ever more frequently, e.g., to report the disciplinary consequences of an Irish teacher who refused to use a student’s gender-neutral pronouns.<sup>1</sup> In this context, the demand for Gender-Inclusive Language (GIL) has grown louder than ever. The responses, however, have been quite disparate. Moreover, the most longstanding debates around gender and language have assumed a binary approach (Stahlberg et al., 2007), thus being incompatible with the rising recognition of non-binary gender identities (Ackerman, 2019).

Towards the avoidance of masculine generics and the inclusion of non-binary identities, two main linguistic strategies have been employed. The first relies on innovative linguistic elements, such as neopronouns (En. *ze/zir* instead of *he/she/him/his/her*) which are emerging from grassroots movements. The use and the acceptance of such forms, however, is still highly debated, and often restricted to informal communication channels like social media (Comandini, 2021). As a viable alternative that we explore in this work, neutral language that avoids gender marking (e.g., *chairperson* instead of *chairman*) has been pro-

<sup>1</sup>See <https://www.cbsnews.com/amp/news/teacher-jailed-for-contempt-of-court-refusing-student-gender-neutral-pronouns-ireland/>.

posed as an inclusive solution that conforms to standard and attested linguistic resources. Along this line, English undoubtedly occupies a predominant role, being recognized as a leader of change towards the deployment of gender-inclusive linguistic strategies (Ackerman, 2019). Comparatively, the situation is more complicated for other languages, due to less timely discussions on linguistic inclusivity within their speaking communities, as well as to their grammatical structures. Indeed, grammatical gender languages such as Italian exhibit an extensive system of morphosyntactic gender agreement, where masculine/feminine distinctions are marked for several parts of speech (e.g., En. *everybody is gone* → It. *tuttile sono andata*). As a result, neutralization strategies devoid of gender marking can entail quite laborious rephrasing (e.g., It. *ogni persona è andata*). In light of the foregoing, inclusive language is intrinsically nuanced and multifaceted, and its implementation highly language-specific. For example, while English speakers can take advantage of a well-accepted gender-neutral pronoun such as the singular *they*,<sup>2</sup> Italian speakers cannot resort to any similarly common devices at the moment. So, how to move across languages in an inclusive manner? To date, answers to this question are in need. In fact, while some monolingual systematizations towards language inclusivity have emerged (see the analysis in Section 3), cross-lingual settings such as translation are still largely unexplored and lack an actionable conceptual framework of reference.

In light of recent studies highlighting that language technologies are affected by gender bias, the adoption of inclusive language in translation assumes a relevant role in Machine Translation (MT), too. Indeed, MT systems were found to systematically prefer masculine forms and stereotypical gender associations in their outputs, thus reinforcing bias and reiterating the under-representation of specific groups. From a slightly different perspective, the analysis by Savoldi et al. (2022) actually revealed that MT models do generate gender-neutral outputs. At a closer inspection, however, their generation appears sporadic, unintentional, and the finding incidental. The study, in fact – just like other existing work in MT (Savoldi et al., 2021) – was specifically designed to explore gender bias within a bi-

nary framework. Dedicated inquiries on gender-neutral MT, instead, are largely absent, also hindered by the current lack of data resources, benchmarks, which in turn limit the development of inclusive models. Such a gap calls for dedicated work on this topic, starting from the definition of the objectives and the main challenges to be faced when developing gender-neutral MT systems.

In light of this, in the present work we discuss a roadmap towards the integration of inclusive language in translation, with a focus on MT. Specifically, we discuss Gender-Neutral Translation (GNT) as an actionable form of gender-inclusive translation; we focus on gender neutralization strategies in the context of English-Italian translation, as representative of the translation pairs which include a grammatical gender language as target. To this aim, we present three contributions. *i*) We provide a thorough analysis of relevant English and Italian guidelines for GIL, aimed to inventory established neutralization strategies (see Section 3), in the wake of which *ii*) we propose a list of desiderata for GNT (see Section 4). Finally, *iii*) we discuss the challenges of implementing such desiderata in the context of MT (see Section 5).

## 2 Background

The relationship between gender and language is socially relevant: several studies showed how the expression of gender in language relates to the visibility of gender groups and sexism (Wasserman and Weseley, 2009; Prewitt-Freilino et al., 2012). At the same time, language mirrors social change, as exemplified by the increase of feminine forms in literary text, reflecting the improvement of women’s status (Twenge et al., 2012). Such correlations thus manifest the social and political value of our communicative practices. Accordingly, language interacts with the perception and representation of individuals (Gygax et al., 2019; Corbett, 2013; Stahlberg et al., 2007), and gender expressions are socially relevant categories to talk about the self and others. Thus, their appropriate use is critical for both human (see Section 2.1) as well as automatically generated (see Section 2.2) language.

### 2.1 Gender and Language

The notion of gender is complex and debated, and it has been observed and discussed extensively

<sup>2</sup>See the APA style guidelines: <https://apastyle.apa.org/style-grammar-guidelines/grammar/singular-they>

through the lenses of several disciplines. Gender encompasses both social and individual aspects (Kiesling, 2019). As an overarching social categorization, it relates to the status that has been traditionally associated with femininity and masculinity in terms of traits, practices, or roles (Lindsey, 2015). Individually, our experience of gender contributes to the construction of our identity and our positioning within society (Crenshaw, 1991).

The notion of gender is so relevant to human experience that no language lacks expressions of femaleness or maleness altogether (Stahlberg et al., 2007). However, languages differ in how they encode gender. For example, English is a notional gender language which expresses the gender of human referents mostly through personal pronouns and possessive adjectives (e.g., *he/him/hers; she/her/hers*), while sometimes also relying on lexically gendered forms (e.g., *man; woman*), and a few other elements, such as compounds (e.g., *chairman/chairwoman*). Differently, grammatical gender languages such as Italian are characterized by a system of morphosyntactic agreement, where several parts of speech beside the noun (e.g., verbs, determiners, adjectives) carry gender inflections, as in *I/Le bambini/bambine sono contenti/contente* (En. *The children are happy*).

Regardless of grammatical differences, gender representation in language implicates a disparity in the representation of the genders. It reiterates and reinforces social asymmetries through discriminatory practices. Part of such discriminatory practices rest on normative and stereotypical principles. Androcentric normativity promotes the masculine gender as the human prototype, the norm, encompassing the whole human experience (Pauwels, 2003). Women are thus treated as a gendered deviation from this male default, and non-binary experiences are excluded from representation. A typical manifestation of normativity in language is the masculine generic, namely the use of masculine forms as conceptually generic, neutral (e.g., *one must watch his language*), when referring to mixed-gender groups or when gender is unknown or unspecified. Stereotypes, instead, are reiterated and reinforced in the assumption of someone's gender through associations of professional nouns and gender (e.g., *nurse* = feminine, *doctor* = masculine) (He, 2010), fostering gender paradigms that limit opportunities and contribute to an unfair social system.

In light of this, we look at Gender-Inclusive Language<sup>3</sup> for the avoidance of stereotypical and discriminatory language. This is a form of *verbal hygiene* (Cameron, 1995) by which people attempt to regulate language *i*) in conformity to certain ideals, and *ii*) by promoting linguistic policies that reflect them. Such policies, however, can differ significantly, even within the context of GIL. (Motschenbacher, 2014) mentions two relevant strands of gender-related linguistic policies: *i*) non-sexist, which address the structures that make women invisible or represent them as deviant from the male norm; and *ii*) non-heteronormative, which counter language constructs that assume heterosexuality as normal, desired or preferable, such as the exclusive use of 'binarily' gendered forms. Though seemingly aligned in scope, it should be noted how these two types of policies are not always compatible. A case in point regards the non-sexist practice of using a double gender specification (e.g., *he or she*), which is binary and thus discouraged in non-heteronormative language policies.

Avoiding gendered expressions in grammatical gender languages has led to the appearance of innovative approaches from grassroots efforts. These innovations, quite disparate in nature, tend to focus on direct forms of inclusive language, i.e., neopronouns, neomorphemes, and other resources that allow to address and mention the referent directly, without resorting to generic terms or mincing words. One of the most successful examples of such phenomena is the personal neopronoun *hen* in Swedish (Hord, 2016), which is meant to be a gender-neutral alternative to the masculine and feminine counterparts *han* and *hon*. In Italian, similar innovative proposals have emerged, such as the *-u* and *-ə* neomorphemes (Comandini, 2021) which try to retool an already existing sound of the language in the first case and to add a new one in the latter, in order to implement a gender-neutral option within the Italian morphology. The adoption of gender-inclusive innovations, however, is inconsistent across different languages. While the Swedish neopronoun *hen* has been accepted

<sup>3</sup>The label "inclusive language" covers a wide range of practices aimed at avoiding discrimination and denigration on any basis (class, race, religion, and gender; see APA, 2021). Such practices have also been given several different labels: 'inclusive', 'neutral' and 'fair' are some of the most common ones found in the collection of guidelines we discuss in Section 3. To set the object of our analysis within a larger scope of inclusivity, we hereby rely on the label *gender-inclusive language*.

by speakers and institutions, the same cannot be said of most of its equivalents in other languages. The Italian Accademia della Crusca, for example, has expressed against gender-neutral innovations to the language.<sup>4</sup>

Since gender-inclusive innovations are still considered ungrammatical and their use is discouraged in most contexts, speakers who wish to use a GIL tend to resort to established devices of the standard language. The prevalent category among those devices is that of gender-neutralization strategies, such as the preference for epicene words, i.e. words that are not gender-marked and can be used regardless of the referent's gender (e.g., *spokesperson*, as opposed to *spokesman* and *spokeswoman*). Neutralization strategies range from simple word choices to complex sentence formulations that, avoiding the introduction of innovative elements into the language, are largely acceptable. Consequently, we look at gender neutralization as an actionable and acceptable form of GIL and a solid ground for the exploration of cross-lingual scenarios, namely translation and automatic translation.

## 2.2 Gender (Bias) and Machine Translation

Language technologies have become ubiquitous and play a significant role in our lives, with the danger of amplifying certain biased behaviors (Blodgett et al., 2020). For this reason, concerns about fairness are arising, and some of them affect gender. Such technologies, indeed, have been shown to generally discriminate against certain individuals or groups with specific gender identities in favor of others (Sun et al., 2019, *inter alia*). This tendency is defined as *gender bias* (Stanczak and Augenstein, 2021).

Although affecting many monolingual tasks, gender bias comes across even more evident in cross-lingual scenarios, such as the case of MT, where different languages can encode very different gender marking mechanisms. In this task, indeed, models have been shown to have a tendency towards masculine default translations (e.g., En. *The student* → It. *Lo* (M) *studente*) or stereotypical translations (e.g., En. *The doctors and the nurses* → It. *I dottori* (M) e *le infermiere* (F)) (Cho et al., 2019; Prates et al., 2020; Bentivogli et al., 2020; Savoldi et al., 2021; Costa-jussà et al., 2020, *inter alia*). Gender bias has both technical and societal

implications. From a technical perspective, the erroneous translation of gender clearly deteriorates the performance of the systems. From a societal perspective, gender bias in translation technologies may contribute to misrepresent feminine entities when misgendered as male, and to reinforce some commonplaces through stereotyped translations. At the same time, it determines an unequal quality of service, where certain groups of users may encounter systematic mistranslations.

Although gender bias is receiving increasing attention in the research community, most efforts to address it still do not go beyond gender binarism. Some works have recently expressed the cruciality of dealing with non-binary identities in Natural Language Processing (NLP) (Cao and Daumé III, 2020; Dev et al., 2021), and two main approaches can be found among the works that have taken this route. Brandl, Cui and Søggaard (2022) focused on neopronouns, showing that language models have difficulties in processing them in Swedish (*hen*), Danish (*de/høn*) and English (*they/xe*). Others focused on standard neutral solutions, for both text classification (Attanasio et al., 2021) and natural language generation tasks, such as gender-neutral rewriting (Sun et al., 2021; Vanmassenhove et al., 2021; Attanasio et al., 2021), which consists in converting gendered forms into their gender-neutral counterparts (e.g., En. *he/she* into singular *they*, *chairman* into *chairperson*). Finally, for the task of coreference resolution, Cao and Daumé (2020) focused on both the solutions, while Lauscher, Crowley and Hovy (2022) adopted a delexicalization approach, by substituting pronouns with part-of-speech placeholders. As regards MT, to the best of our knowledge the sole study addressing gender-neutral forms is by Saunders, Sallis, and Byrne (2020). Working on English → German/Spanish, they created a benchmark to assess the ability of MT systems to generate neutral target sentences. However, similarly to Lauscher, Crowley and Hovy (2022), they avoided choosing a specific neo-morpheme over others and resorted to gender-neutral placeholders for articles and inflectional morphemes (e.g., En. *the trainer* → Es. *DEF entrenadorW\ \_END*).

Overall, adopting a neutral translation can be seen as a path towards both the avoidance of gendered inferences and the use of language that is inclusive of different gender groups. The specific challenges that this endeavor poses for MT, how-

<sup>4</sup>See <https://accademiadellacrusca.it/it/consulenza/un-asterisco-sul-genere/4018>

ever, are not negligible. On the one hand, the complexity of implementing neutral forms comes from the inherent difficulties posed by grammatical gender languages and by the tension between standard neutral recommended forms and innovative language-specific strategies. With this respect, given the lack of consensus regarding the acceptability of the latter, Saunders, Sallis, and Byrne (2020) refrained from picking which actual neomorphemes systems should be required to generate. On the other hand, the application of an inclusive language must be carefully designed not to be perceived as intrusive nor as a limitation to the freedom of expression. To exemplify this risk, a case in point regards the assistive inclusive writing feature that has recently been incorporated in Google Docs.<sup>5</sup> When it came out, it was strongly rejected by several users, which unwelcomed some – seemingly spurious – suggestions (e.g., the flagging of *motherboard* as a non-inclusive term).<sup>6</sup> In light of the foregoing, before we confront the technical challenges that arise from neutralization in NLP, and more specifically MT, we need to lay the groundwork for this endeavor. That is, framing the linguistic possibilities that could be adopted towards an automatic neutral translation, and identifying their suitable deployment.

### 3 Review of Guidelines for Gender-Inclusive Language

Looking for guidance to approach GIL, the most influential and immediately available resources are the guidelines produced and released by renowned institutions to address gender discrimination in language. We consider them ‘top-down’ approaches, as opposed to the ‘bottom-up’ efforts of grassroots movements. Although institutional guidelines are currently exclusively monolingual, while our domain of interest is translation, we analyze them to collect useful inclusive linguistic strategies focusing on gender neutralization. More precisely, we intend to *i*) explore how gender inclusivity is conceptualized within such guidelines, and *ii*) gain insights concerning *what* should be neutralized in language and *how*. To this aim, we

selected 30 guidelines<sup>7</sup> published online<sup>8</sup> by relevant institutions, equally divided between guidelines for English and Italian. Besides prestige, we prioritized comparability: we selected guidelines by international institutions (e.g., EU) that published the same document in both languages, or by national institutions (e.g., universities and governmental bodies) that share a similar status across countries, thus also ensuring that the selected guidelines belong to the same textual genre.

Starting from *how these inclusive guidelines interpret gender*, and hence gender-based discrimination, we find clear differences between the English and the Italian documents. While the former mostly adopt a non-heteronormative outlook – explicitly going beyond the binary gender framework – the Italian guidelines tend to address women and men only. Such a difference emerges clearly in the two versions of the European Parliament’s guidelines (see documents E3, I5 in the reference list). This fundamental difference entails different ideas of discrimination (e.g., E3: “achieving equality”, I5: “achieving equality between men and women”). Consequently, this conceptual discrepancy is reflected in the suggested strategies to address discrimination at the linguistic level. For instance, the Italian guidelines provide extensive lists of feminine counterparts for traditionally masculine professional nouns (e.g., En. *coordinator* as It. *coordinatore* [M] - *coordinatrice* [F]). Also, they often endorse gender specification to avoid masculine generics (e.g., En. *The professors are in a meeting* as It. *I professori* [M] *sono in riunione* → - *I professori* [M] *e le professoressa* [F] *sono in riunione*.) Since such suggestions remain within a binary framework, they are irrelevant to our gender-neutral goal, and hence discarded in our upcoming discussion of inclusive strategies.<sup>9</sup>

Moving onto *the neutralization strategies* to implement GIL, in Table 1 we offer an extensive systematization through a multilingual perspective that – except for highly language-specific solutions that are impossible to transfer – attempts to map strategies across English and Italian. In the table, the strategies are presented in contrast to non-

<sup>5</sup>See <https://blog.google/products/workspace/google-workspace-features/>.

<sup>6</sup>See <https://news.sky.com/story/google-docs-criticised-for-woke-inclusive-language-suggestions-12598687>.

<sup>7</sup>The full list is available at the following link <https://docs.google.com/document/d/18vtbLQzYmTjnDsXj06rbm9FbQMHcVvpQ2Lv99xuzi2k/edit?usp=sharing>

<sup>8</sup>Retrieved through Google queries on 28/10/2022.

<sup>9</sup>Similarly, we do not treat suggestions on how to e.g., avoid hate speech contained within these guidelines, as they exceed the gender-neutral oriented scope of this review.

Inclusive strategy	English		Italian	
	GL	Example	GL	Example
A. Epicene synonyms	E5	<i>Chairman</i> → <i>Chair, chairperson</i>	I3	<i>Professore</i> [Professor] → <i>Docente</i> [Teacher]
B. Pluralization (towards generic or epicene forms)	E2	A judge must certify that <i>he</i> has familiarized <i>himself</i> with... → All judges must certify that <i>they</i> have familiarized <i>themselves</i> with...		
C. Relative and indefinite pronouns	E5	If a staff member is not satisfied..., <i>he</i> can ask for a rehearing. → Any staff member <i>who</i> is not satisfied... can ask for a rehearing	I3	L'assicurazione... è a carico <i>del fruitore</i> [of the user]. → a carico di <i>chi fruisce</i> [of who uses]
D. Collective and Role nouns	§	Please contact one of the <i>waiters</i> . → Please contact our <i>staff</i> .	I3	Il palazzo ospita gli studi <i>dei professori</i> [of the professors] di slavo. → ... gli studi <i>del personale docente</i> [of the teaching staff] di slavo.
E. Omission	E2	A person must reside... before <i>he</i> may apply for permanent residence. → before __ applying for permanent residence.	I3	Un'accurata compilazione... facilita <i>allo studente</i> [to the student] diverse operazioni. → facilita __ diverse operazioni.
F. Repetition	E3	A manager may apply... if permission has been granted by <i>his</i> institution. → if permission has been granted by <i>that manager's</i> institution.		
G. Passive voice	E5	Each action officer must send <i>his</i> document. → Documents <i>must be sent</i> .	I1	<i>Il richiedente</i> presenta la domanda. [The applicant submits the application] → La domanda <i>va presentata</i> [The application must be submitted].
H. Imperative forms	E5	Each staff member is requested to submit <i>his</i> information. → Please <i>submit</i> all information.	§	<i>Il cittadino</i> deve allegare [The citizen must attach] <i>un documento</i> . → <i>Allega</i> [Attach] <i>un documento</i> .
I. Impersonal forms			I15	<i>Il candidato</i> decade [The candidate loses] <i>dal diritto</i> ... → <i>Si decade</i> [*One loses] <i>dal diritto</i> ...

**Table 1:** Examples of neutralization strategies. In **red** the generic masculine formulations, in **green** the corresponding gender-neutral forms. In the 2nd and 4th column, we provide the reference to the guidelines from which they were extracted (E1,2,3,..). If no example was found for that specific strategy and language within the guidelines, but the strategy could nonetheless be possible, we fabricated an example and indicated it with the § symbol. If a strategy is not possible to implement in one of the two languages, the respective box is left empty.

inclusive examples. Note that their systematization reflects different ways of realizing gender neutralization, which shows higher variability.

Concerning *what should be neutralized*, in fact, we identify that these documents tend to largely focus on a particular form of gender discrimination, namely, masculine generics. Masculine generics have been historically employed in administrative/legal-oriented texts to briefly refer to the public at large (e.g., see example B, where

*he* refers to the whole occupational category of *judges*, and the Italian *il docente* [M], *professor* for the full teaching body). In the same vein, androcentric forms are discouraged (e.g., see example A in English). Though more briefly, it is also discussed how GIL should avoid stereotypical associations.

This, indeed, is crucial to translation, where cross-lingual transfer risks relying on stereotypes (e.g., *nurses* rendered as F, and *doctors* as M in

Italian). All in all, we can see how these guidelines are mostly concerned with generic referents. As we will discuss in Section 4, however, there are also other circumstances where avoiding gender marks is necessary, e.g., to avoid misgendering individuals.

Finally, and from a linguistic standpoint, we underscore that – as expected – English GIL strategies focus on the neutralization of pronouns (e.g., C, E), which are the main carrier of gender distinction in notional languages. Instead, Italian guidelines prioritize the neutralization of nouns (see E for an exception concerning an article), thus discarding adjectives, pronouns, and verbs, which are subject to gender agreement, too. Although the analyzed sentences are simple and presented as toy examples within an institutional genre, effective solutions for a diverse range of communicative situations shall not overlook the full range of gendered words in grammatical gender languages such as Italian.

In light of the foregoing, we now delve into *how to avoid gender discrimination in language*. As previously anticipated, these top-down guidelines advocate for the use of neutralization strategies that conform to standardized, institutional language, rather than innovative, uncertain forms. As shown in Table 1, neutral solutions can greatly vary, ranging from omissions (e.g., E), and simple replacements of single words via unmarked synonyms (e.g., A, B, D via epicene or collective nouns), to more complex reformulations that involve structural changes at the sentence level (e.g., F, G, H, I). On the one hand, though elegant, nouns replacement might be limiting if other gender-marked words are present, and only allow for a partial neutralization, e.g., as in It. *Il [M] professore [M] è tenuto [M] a rispondere* (En. *The professor must answer*) neutralized as *L'insegnante è tenuto [M]*. When possible, however, the neutralization of short segments seems to be a preferable dimension to consider to make the outcome more fluent, as opposed to more complex phrasings. This strategy is not always viable, though. Consider, for instance, the Italian term “*figlio/a*” (En. *child*): in lack of epicene synonyms, neutralization would require verbose periphrases, e.g., It. *minore a carico* (En. *underage, dependent child*) or *persona che si è concepita o adottata* (En. *person who was conceived or adopted*). In light of this, neutralization strate-

gies emerge as complex choices, to be carefully selected and weighted so as to preserve the acceptability of a text, i.e. fluency, style. Such choices, of course, highly depend on various constraints (e.g., register, length, the context of use). Therefore, when adopting inclusive language, it is crucial to consider the possible trade-off between neutrality and the overall acceptability of the text where it is implemented.

As a final consideration, we highlight that in the guidelines (as also reflected in Table 1) gender-inclusive solutions are presented as a process of reformulation. Namely, as an additional rephrasing step to be applied to gender-marked expressions. To a certain extent, it resembles a (monolingual) rewriting process, which is not ideal for translation. Indeed, the adoption of such a post-editing approach in translation would completely exclude the direct interpretation of the source sentence to be neutralized, thus compromising its apt transfer and careful decisions on *when* and *how* to neutralize. With this in mind, and in light of both insights and shortcomings that emerged in this Section, we now specifically address the use case of Gender-Neutral Translation.

#### 4 Desiderata for a Gender-Inclusive Translation

While many monolingual guidelines are available for GIL, the same cannot be said about Gender-Inclusive Translation. Currently, results available online for search queries like ‘gender-inclusive translation guidelines’(En.) and ‘linee guida traduzione inclusiva’(It.) only provide a few *tips and tricks* blog posts for translators, in addition to monolingual guidelines. This is rather unfortunate, as translation poses other cross-lingual challenges. In this Section we define and discuss gender-neutral translation (GNT) as a form of gender-inclusive translation, which allows for the avoidance of discriminatory practices while conforming to the standard language. We define GNT as a translation that does not mark the gender of human referents if they are not assigned with a particular gender in the source text. For example, given the English sentence *Your neighbors will thank you*, one possible Italian GNT is *Il vostro vicinato<sup>10</sup> vi ringrazierà*, as opposed to *I vostri*

<sup>10</sup>While the word *vicinato* is formally masculine, as a collective noun referring to a group of people it is conceived as conceptually neutral.

(1)	En.	<i>I refuse to give up on a <b>single student</b> in my class.</i>
	It.	<i>Mi rifiuto di lasciare indietro <b>un solo studente</b> nella mia classe.</i>
	GNT	<i>Mi rifiuto di lasciare indietro <b>qualsiasi studente</b> nella mia classe.</i>
(2)	En.	<i>A lot of <b>innovative teachers</b> began bringing comics...</i>
	It.	<i><b>Molti insegnanti innovativi</b> iniziarono a portare i fumetti...</i>
	GNT	<i><b>Un gran numero di insegnanti all'avanguardia</b> iniziarono a portare i fumetti...</i>
(3)	En.	<i>We train <b>nurses</b> to do it, and they use local anesthetics.</i>
	It.	<i>Formiamo <b>le infermiere</b> a farlo, e loro usano anestetici locali.</i>
	GNT	<i>Formiamo <b>il personale infermieristico</b> a farlo, e loro usano anestetici locali.</i>
(4)	En.	<i>Vehicles may only proceed <b>at walking pace</b>.</i>
	It.	<i>I veicoli possono procedere solo <b>a passo d'uomo</b>.</i>
	GNT	<i>I veicoli possono procedere solo <b>a passo di persona</b>.</i>
(5)	En.	<i>Were you <b>supernerdy</b> as a girl?</i>
	It.	<i>Eri molto <b>sfigata</b> da ragazza?</i>
(6)	En.	<i>It affects one to two percent of the population, more commonly <b>men</b>.</i>
	It.	<i>Riguarda dall'uno al due per cento della popolazione, ed è più comune negli <b>uomini</b>.</i>
(7)	En.	<i>The <b>fishermen</b> were so <b>upset</b> about not having enough fish to catch that...</i>
	It.	<i>I <b>pescatori</b> erano così <b>disperati</b> per la mancanza di pesce da pescare che...</i>
	GNT	<i><b>Le persone che pescavano</b> erano così <b>disperate</b> per la mancanza di pesce da pescare che...</i>
(8)	En.	<i>Now when I was a <b>freshman</b> in college, I took my first biology class.</i>
	It.	<i>Quando ero <b>uno studente al primo anno</b> di università, seguì il mio primo corso di biologia.</i>

**Table 2:** Examples for desiderata D1-3.

*vicini vi ringrazieranno*, which features a masculine generic. As discussed in Section 3, the extent to which a GNT is easy to produce, viable and appropriate heavily depends on the context and the content of the source text. Having in mind the necessary trade-off between neutrality and linguistic acceptability, as a rule of thumb we claim that – within the range of gender neutralization possibilities – it is preferable to choose the option that diverges the least from a typical and fluent translation, while maintaining semantic coherence with the source text. Moreover, it is crucial to determine when it should be adopted. To this aim, also informed by our analysis of the existing guidelines, we devise three main desiderata.

**D1. Avoid expressing gender in the translation when it cannot be properly assumed in the source.** While translating from one language to another, a GNT should be used only if the gender of the referent(s) cannot be inferred from the source. This scenario could be quite frequent in translations from a notional gender language into a grammatical gender one. In this case, a GNT refrains from any gratuitous assumptions, thus avoiding expressions which may: *i*) misgender a specific referent (see Table 2, Ex. 1); *ii*) exclude a social group, such as in the case of masculine generics (see Table 2, Ex. 2); *iii*) foster stereotypical associations (see Table 2, Ex. 3); adopt androcentric expressions (see Table 2, Ex. 4). In these examples, we mark in red the gender-marked expressions falling into the binary category, and in

green those that are neutral.

**D2. Use proper expressions of gender in the translation when (indirectly) expressed in the source.** The gender of some entities can be sometimes inferred by linguistic elements, which we may define as “gender cues”. For example, gender cues are 3rd person pronouns (*he/him/his, she/her/hers*), terms of address (e.g., *Mr./Mrs./Ms.*), gender-specific nouns (e.g., *boy, lady, lord, wife*) (see Table 2, Ex. 5). First names, surnames, or even nicknames should not be included among these cues for several reasons. First, names can hardly be considered a reliable index of someone’s gender identity (see Lauscher et al., (2022)). Even in the attempt of any binary correlation, names are highly ambiguous across genders and cultures (e.g., *Andrea*, which is typically masculine in Italian, but feminine in German). Clearly, the same applies to nicknames. Finally, the combination of first name and surname is borderline: though they are attributable to a specific person, their gender expression depends on whether that person’s gender is directly known, and this may require a world knowledge not always ensured (e.g., the singer Demi Lovato, who has defined themselves as non-binary).<sup>11</sup> In addition, referents’ gender could be known also through non-textual elements, such as explicit external information about who is speaking, which sometimes is

<sup>11</sup>See <https://www.rollingstone.com/music/music-news/demi-lovato-non-binary-coming-out-pronouns-1171379/>

provided to the translators. In all these cases, gender expressions are preferable in the translation.

**D3. Avoid propagating masculine generics from source to translation.** In spite of the seemingly straightforward definition of gender cues in D2, their recognition is not clear-cut. This is the case of masculine generics used in the source, whose distinction from an actual gender cue might be equivocal. Hence, every information should be carefully evaluated, in particular the compounds of *-man*, so as to understand if they are used properly. For instance, to explicitly refer to the masculine gender group (see Table 2, Ex. 6), where a neutralization would effectively compromise the meaning of the sentence. Differently, terms such as *fishermen* and *freshmen* are often deployed as masculine generics to refer to the whole category (see Table 2, Ex. 7), and thus should be translated with neutral forms. As a final rule of thumb, however, there is a specific case where gender cues ought to be considered as largely trustworthy; namely, in relation to the speaker as 1st person singular referent (see Table 2, Ex. 8). This is based on the assumption that speakers deliberately choose the most appropriate expressions while talking about themselves. Hence, their choice should be respected in translation.

In conclusion, we have outlined a set of overarching desiderata to guide the proposed definition of GNT. Such desiderata have been paired with suggestions on what and how to neutralize in translation, so as to adopt a more inclusive language in the context of translation. Such a scaffolding represents our proposed set of principles to be applied towards the development of more inclusive MT models.

## 5 Challenges and insights for a Gender-Neutral Machine Translation

Based on the neutralization strategies systematized in Section 3 and their conversion into GNT desiderata in Section 4, we can now delve into their applicability to MT. Indeed, on top of the theoretical and linguistic insights discussed so far, the research direction of a gender-neutral MT also raises several technical challenges. These include dedicated data, metrics and architectures, whose lack necessarily hinders the development of gender-neutral models that satisfy our desiderata.

**Giving value to evaluation.** The creation of dedicated benchmarks underlies the possibility to determine whether systems are actually making any advancements towards automatic GNT. *Ad-hoc* testbeds should frame the desired MT behavior as outlined in the previous Section. Accordingly, the MT benchmarks - traditionally designed as parallel data - should comprise source sentences that require a GNT, aligned with their GNT counterpart in the target language. These human translations should be created following the strategies defined in Section 3. Ideally, the domain of this test set should be based on the institutional/administrative texts from which the guidelines analyzed in Section 3 have been derived, but other domains could be also included to assess GNT in various contexts. Having this test set, however, may not be enough: also a specific evaluation protocol needs to be designed. Generally, automatic MT evaluation is based on similarity-based comparisons between the system outputs and the corresponding human reference translations, which represent a single, not unique way of translating a source sentence. Cast in this way, evaluation conflates and equally penalizes *i*) wrong outputs and *ii*) acceptable outputs that differ from the reference. Language generation, indeed, is an open-ended challenge, for which multiple solutions are possible, especially when periphrases are involved. For this reason, the creation of gender-neutral reference translations is a particularly delicate process, since automatic neutralizations could prove to be hardly detectable in an evaluation pipeline based on single references. In fact, only through manual analyses Savoldi et al. (2022) found some neutral expressions in the outputs of automatic models. Moreover, standard MT evaluation metrics like BLEU (Papineni et al., 2002) only provide a holistic score as an indicator of overall translation quality. Instead, assessing GNT would require a specific protocol and measure, able to focus on the neutralized words and isolate them from other unrelated factors that might affect generic performance. Therefore, a possible solution could be the use of multiple references, containing different neutral realizations (to account for language variability) as well as a gender-marked realization (to identify undesired outputs). Since manually creating multiple reference translations is very costly, an alternative solution could be designing a GNT-oriented quality estimation metric (Specia et al., 2018), which

provides an estimate of whether the output of a MT system is gender-neutral or gender-marked, without accessing any reference.

**Training models without GNT examples.** For current data-driven, neural approaches to MT, large availability of data represents a main bottleneck. If the manual creation and annotation of a few hundreds of test sentences (e.g., to identify source cues, and to determine the most appropriate neutralization strategy) is a viable option for evaluation, the vast amount of training data needed for model development makes manual solutions hardly feasible. To counter data lacking, it would be interesting to explore training-time algorithmic techniques dedicated to teaching systems how to perform GNT. For inspiration, we could approach gender-neutralization through the lens of lexically-constrained MT, i.e., the task of performing a translation in adherence to a set of pre-specified lexical constraints (Hokamp and Liu, 2017; Post and Vilar, 2018; Dinu et al., 2019; Bergmanis and Pinnis, 2021, *inter alia*). Drawing from this line of research, the envisioned “neutrally-constrained” MT could rely on the creation of bilingual dictionaries – mapping source words to desired neutral target words – to be leveraged towards the generation of epicene forms. As examined in Section 3, however, more invasive interventions towards neutrality are sometimes unavoidable. Interventions that involve more than simple word substitutions do entail a higher cost in terms of adherence to the source text and fluency. Hence, the ideal MT systems should be able to consider the full range of possible neutralization strategies, so as to plan and find the preferable course of actions starting from the least to the costliest ones. To this aim, a specific training methodology that rewards highly-probable and low-cost outputs, while penalizing less-probable and costlier ones, could be designed to foster minor interventions.

**Disambiguating gender through a wider context.** Currently, state-of-the-art MT works at the sentence level, i.e., by translating each sentence in isolation. Although this approach still yields the most competitive results, alternative solutions that account for larger textual context in translation might be more apt for GNT; in particular, to decide when to perform GNT. As discussed in Section 4, D2-3, in fact, we should not always neutralize, but rather make informed decisions depending

on the presence (or lack) of gender cues. These cues, however, might be available out of the limited sentence-context (e.g., *He was talking with a young man. Only later I realized that this person was his professor*). Accordingly, the design of MT models that translate beyond the sentence level ought to be considered. Translating sentences in a wider context, indeed, has proven crucial for correctly handling discourse cohesion (Bawden et al., 2018), and was shown to a certain extent beneficial to mitigate gender bias (Basta et al., 2020). However, it remains occasionally dubious whether context provides a useful linguistically-motivated knowledge (Kim et al., 2019). Before venturing into any document-level endeavor, it is thus recommended to verify whether there is a positive interpretable link between GNT, context-informed MT which goes beyond the sentence level, and overall quality of the system.

**Disambiguating gender through external knowledge.** Another architectural choice inspired by D2-3 is related to the integration into the model of external information, such as metadata like speakers’ gender information, i.e., their chosen linguistic expressions of gender (Gaido et al., 2020), as a cue to disambiguate gender and avoid unwanted neutralizations. Although MT systems generally exploit only textual data information from the source sentence, the injection of external knowledge is in principle beneficial for gender disambiguation and, in turn, for our GNT purposes. Metadata could be supplied in the form of tags, either at the word level (Saunders et al., 2020; Stafanovičs et al., 2020) or at the sentence level (Elaraby et al., 2018; Vanmassenhove et al., 2018; Basta et al., 2020).

## 6 Conclusions

Gender bias and discrimination in language are rising concerns that have also invested the field of automatic translation, where MT models have been found to amplify male visibility and stereotypes. As a promising route forward to counter this bias, in this work we have taken the first steps towards the adoption of gender-inclusive language in translation. In particular, we have focused on the use of neutral forms devoid of gender marking for an English-Italian setting, so to avoid undue gendering and foster the inclusion of non-binary identities. To this aim, we have conducted an extensive review of the gender neutralization strate-

gies presented in English and Italian monolingual guidelines for inclusivity. On this basis, we have outlined a definition of *gender-neutral translation* suitable for cross-lingual contexts, paired with a set of overarching desiderata to guide its adoption. Finally, we have concluded by weaving together theoretical and linguistic insights, and technical challenges for the implementation of a gender-neutral translation in MT. It is in our hope that our contribution will guide the community towards the development of fairer and more inclusive translation practices and models.
