Editor: Submitted to the Journal of Machine Learning Research

#### Abstract

Inference efforts - required to compute partition function, $Z$, of an Ising model over a graph of $N$ "spins" - are most likely exponential in $N$. Efficient variational methods, such as Belief Propagation (BP) and Tree Re-Weighted (TRW) algorithms, compute $Z$ approximately minimizing respective (BP- or TRW-) free energy. We generalize the variational scheme building a $\lambda$ - fractional- homotopy, $Z^{(\lambda)}$, where $\lambda=0$ and $\lambda=1$ correspond to TRW- and BP-approximations, respectively, and $Z^{(\lambda)}$ decreases with $\lambda$ monotonically. Moreover, this fractional scheme guarantees that in the attractive (ferromagnetic) case $Z^{(T R W)} \geq Z^{(\lambda)} \geq Z^{(B P)}$, and there exists a unique ("exact") $\lambda_{*}$ such that, $Z=Z^{\left(\lambda_{*}\right)}$. Generalizing the re-parametrization approach of (Wainwright et al., 2001) and the loop series approach of (Chertkov and Chernyak, 2006a), we show how to express $Z$ as a product, $\forall \lambda: Z=Z^{(\lambda)} \mathcal{Z}^{(\lambda)}$, where the multiplicative correction, $\mathcal{Z}^{(\lambda)}$, is an expectation over a node-independent probability distribution built from node-wise fractional marginals. Our theoretical analysis is complemented by extensive experiments with models from Ising ensembles over planar and random graphs of medium- and large- sizes. The empirical study yields a number of interesting observations, such as (a) ability to estimate $\mathcal{Z}^{(\lambda)}$ with $O\left(N^{4}\right)$ fractional samples; (b) suppression of $\lambda_{*}$ fluctuations with increase in $N$ for instances from a particular random Ising ensemble.

Keywords: Graphical Model, Partition Function, Free Energy, Tree Re-Weighted Algorithm, Belief Propagation Algorithm, Re-parametrizations, Loop Calculus, MCMC.

## 1 Introduction

Graphical Models (GM) is a major tool of Machine Learning which allows to express complex statistical correlations via graphs. Ising models are most wide-spread GM expressing correlation between binary variables associated with nodes of a graph where probability is factorized into a product of terms each associated with an undirected edge of the graph. Many methods of inference and learning in GM are, first, tested on Ising models and then generalized, e.g. beyond binary and pair-wise assumptions.

[^0]In this manuscript we focus on computing the normalization factor, $Z,-$ called partition function - over the Ising models. The problem is known to be of the sharp-P complexity, that is likely requiring computational efforts which are exponential in the size (number of nodes, $N$ ) of the graph (Welsh, 1991; Jerrum and Sinclair, 1993; Goldberg and Jerrum, 2015; Barahona, 1982). There are three general approximate methods to compute $Z$ : (a) elimination of (summation over) the variables one-by-one (Dechter, 1999; Dechter and Rish, 2003; Liu and Ihler, 2011; Ahn et al., 2018); (b) variational approach (Yedidia et al., 2001, 2005); (c) Monte Carlo (MS) sampling (Andrieu et al., 2003). (See also reviews (Wainwright and Jordan, 2007; Chertkov, 2023) and references there in.) In this manuscript we develop the last two of the methods. We also pay a special attention to providing and tightening approximation guarantees. We build our novel theory and algorithm on the provable upper bound for $Z$ associated with the so-called Tree Re-Weighted (TRW) variational approximation (Wainwright et al., 2003, 2005) and also on the Belief Propagation (BP) variational approximation (Yedidia et al., 2001, 2005) which is known to provide a lower bound on $Z$ in the case of an attractive (ferromagnetic) Ising model (Ruozzi, 2012). Notice that there also exist additional upper bounds derived from log-determinant relaxations, wherein binary graphical models are relaxed to Gaussian graphical models on the same graph (Wainwright and Jordan, 2006; Ghaoui and Gueye, 2008). However, these bounds are generally considered to be loose, and to the best of our knowledge, there is no known method to effectively narrow the gap between these upper bounds and the exact partition function.

### 1.1 Relation to Prior Work

In addition to the aforementioned relations to foundational work on the variational approaches (Yedidia et al., 2001, 2005), MCMC approaches (Andrieu et al., 2003), and lower and upper variational bounds (Ruozzi, 2012; Wainwright et al., 2003), this manuscript also builds on recent results in other related areas, in particular:

- We extend the ideas of parameterized homotopy, interpolating between BP (Yedidia et al., 2001, 2005) and TRW (Wainwright et al., 2003, 2005), in the spirit of the fractional BP (Wiegerinck and Heskes, 2002; Chertkov and Yedidia, 2013), and therefore introducing a broader family of variational approximations.
- Extending on the previous remark - since our approach can be considered as a homotopy bridging the TRW and BP approximations for the GM's partition function, it seems appropriate to cite (Knoll et al., 2023), where another homotopy continuationbased approach was unveiled. The homotopy discussed in (Knoll et al., 2023) is of an annealing type - it starts with the trivial (high-temperature) model where all components are independent and then the potentials of the pair-wise model were tuned gracefully, adjusting the scaling parameter from 0 to 1 . At every incremental step, a BP algorithm was employed to track the fixed point, ensuring the method's precision and reliability. The primary objective of this approach was to surpass the conventional BP in both accuracy and convergence rates. In contrast, our approach is designed to ascertain the exact values of the partition function and marginals, thus setting a new standard for precision in the analysis of complex systems.
- We utilize and generalize re-parametrization (Wainwright et al., 2001), gauge transformation and loop calculus (Chertkov and Chernyak, 2006a b; Chertkov et al., 2020) techniques, as well as the combination of the two (Willsky et al., 2007).
- Our approach is also related to development of MCMC techniques with polynomial guarantees, the so-called Fully Randomized Polynomial Schemes (FPRS), developed specifically for Ising models of a specialized, e.g., attractive (Jerrum and Sinclair, 1993) and zero-field, planar (Gómez et al., 2010; Ahn et al., 2016) types.

### 1.2 This Manuscript's Contribution

We introduce fractional variational approximation interpolating between, by now classical, Tree Re-Weighted (TRW) and Belief Propagation (BP) cases. The fractional free energy, $\bar{F}^{(\lambda)}=-\log Z^{(\lambda)}$, defined as minus logarithm of the fractional approximation to the exact partition function, $Z=\exp (-\bar{F})$, requires solving an optimization problem, which is achieved practically by running a fractional version of one of the standard message-passing algorithm. Parameter $\lambda \in[0,1]$ interpolates between the $\lambda=1$ and $\lambda=0$ cases, corresponding to BP and TRW, respectively. The interpolation technique, in particular our focus on $\lambda_{*}$ which is somewhere in between $\lambda=0$ and $\lambda=1$ and for which $Z^{\left(\lambda_{*}\right)}=Z$, is novel - to the best of our knowledge this is the first manuscript where the interpolation technique is discussed. Basic definitions, including problem formulation for the Ising models and variational formulation in terms of the node and edge beliefs (proxies for the respective exact marginal probabilities), are given in Section 2. Assuming that the fractional message-passing algorithm converges we study dependence of the fractional free energy on the parameter, $\lambda$, and relation between the exact value of the free energy (minus logarithm of the exact partition function) and the fractional free energy. We report the following theoretical results:

- We show in Section 3 that $\bar{F}^{(\lambda)}$ is a continuous and monotone function of $\lambda$ (Theorem 1 proved in Appendix B) which is also concave in $\lambda$ (Theorem 2).
- Our main theoretical result, Theorem 4, presented in Section 4 and proven in Appendix C, states that the exact partition function can be expressed as a product of the variational free energy and of the multiplicative correction, $Z=Z^{(\lambda)} \mathcal{Z}^{(\lambda)}$. The latter multiplicative correction term, $\mathcal{Z}^{(\lambda)}$, is stated as an explicit expectation of an expression over a well-defined "mean-field" probability distribution, where both the expression and the "mean-field" probability distribution are stated explicitly in terms of the fractional node and edge beliefs. We note that such a bridge between exact partition function and approximate partition function, known under the name of Loop Series/Calculus was introduced in Chertkov and Chernyak (2006a b) and also elaborated upon in Willsky et al. (2007) for the case of the Bethe (Belief Propagation), where $\lambda=1$, however to the best of our knowledge it was not reported in the literature for any other values of $\lambda \in[0,1$ [ interpolating between BP and TRW, in particular for $\lambda=0$ corresponding to TRW.

The theory is extended with experiments reported in Section 5. Here we show, in addition to confirming our theoretical statements (and thus validating our simulation settings) that:

- Dependence of $\bar{F}^{(\lambda)}$ and $\log \mathcal{Z}^{(\lambda)}$ on $\lambda$ is of a phase transition type when we move from the TRW regime at $\lambda=0$ to BP regime at $\lambda>\bar{\lambda}$.
- Evaluating $Z^{(\lambda)} \mathcal{Z}^{(\lambda)}$ at different values of $\lambda$ and confirming that the result is independent of $\lambda$ suggests a novel approach to a reliable and efficient estimate of the exact $Z$ the Fractional Message Passing Algorithm 1.
- Analyzing ensembles of the attractive Ising Models over graphs of size $N$ we observe that fluctuations of the value of $\lambda_{*}$ within the ensemble, where $Z^{\left(\lambda_{*}\right)}=Z$, decreases dramatically with an increase in $N$. This observation suggest that estimating $\lambda_{*}$ for an instance from the ensemble allows efficient approximate evaluation of $Z$ for any other instances from the ensemble.
- Studying the sampling procedure to estimate $\mathcal{Z}^{(\lambda)}$, we observe that the number of samples required for the estimate is either independent on the system size, $N$, or possibly grows relatively weekly with $N$. This observation confirms that our approach to estimation of $Z$, consisting in evaluation of $Z^{(\lambda)}$ by a message-passing, then followed by drawing a small number of samples to estimate the correction, $\mathcal{Z}^{(\lambda)}$, is sound.
- Analysis of the mixed Ising ensembles (where attractive and repulsive edges alternate) suggests that for instances with sufficiently many repulsive edges finding, $\lambda_{*} \in[0,1]$ may not be feasible.
We have a brief discussion of conclusions and path forward in Section 6.

## 2 Technical Preliminaries

### 2.1 Ising Models: the formulation

Graphical Models (GM) are the result of a marriage between probability theory and graph theory designed to express a class of high-dimensional probability distribution which factorize in terms of products of lower dimensional factors. The Ising model is an exemplary GM defined over an undirected graph, $\mathcal{G}=(\mathcal{V}, \mathcal{E})$. The Ising Model is stated in terms of binary variables, $x_{a}= \pm 1$, and singleton factors, $h_{a} \in \mathbb{R}$, associated with nodes of the graph, $a \in \mathcal{V}$ and pair-wise factors, $J_{a b} \in \mathbb{R}$, associated with edges of the graph, $(a, b) \in \mathcal{E}$. The probability distribution of the Ising model observing a state, $\boldsymbol{x}=\left(x_{a} \mid a \in \mathcal{V}\right)$ is

$$
\begin{align*}
p(\boldsymbol{x} \mid \boldsymbol{J}, \boldsymbol{h}) & =\frac{\exp (-E(\boldsymbol{x} ; \boldsymbol{J}, \boldsymbol{h}))}{Z(\boldsymbol{J}, \boldsymbol{h})},  \tag{1}\\
Z(\boldsymbol{J}, \boldsymbol{h}) & \doteq \sum_{\boldsymbol{x} \in\{ \pm 1\}|\mathcal{V}|} \exp (-E(\boldsymbol{x} ; \boldsymbol{J}, \boldsymbol{h})),  \tag{2}\\
E(\boldsymbol{x} ; \boldsymbol{J}, \boldsymbol{h}) & \doteq \sum_{(a, b) \in \mathcal{E}} E_{a b}\left(x_{a}, x_{b}\right),  \tag{3}\\
\forall(a, b) \in \mathcal{E}: & E_{a b}=-J_{a b} x_{a} x_{b}-\left(h_{a} x_{a}+h_{b} x_{b}\right) / 2, \tag{4}
\end{align*}
$$

where $\boldsymbol{J} \doteq\left(J_{a b} \mid(a, b) \in \mathcal{E}\right), \boldsymbol{h}=\left(h_{a} \mid a \in \mathcal{V}\right)$ are the pair-wise and singleton vectors, assumed given, $E(\boldsymbol{x} ; \boldsymbol{J}, \boldsymbol{h})$ is the energy function and $Z(\boldsymbol{J}, \boldsymbol{h})$ is the partition function. Solving the Ising model inference problem means computing $Z$ - which is, generally, requires efforts that are exponential in $N=|\mathcal{V}|$.

### 2.2 Exact Variational Formulation

Exact variational approach to computing $Z$ consists in restating Eq. (2) in terms of the following Kullback-Leibler distance between $\exp (-E(\boldsymbol{x} ; \boldsymbol{J}, \boldsymbol{h}))$ and a probability distribution, $\mathcal{B}(\boldsymbol{x}) \in\{-1,1\}^{|\mathcal{V}|}, \sum_{\boldsymbol{x}} \mathcal{B}(\boldsymbol{x})=1$, called belief:

$$
\begin{equation*}
\bar{F}=-\log Z=\min _{\mathcal{B}(\boldsymbol{x})} \sum_{\boldsymbol{x}}(E(\boldsymbol{x}) \mathcal{B}(\boldsymbol{x})-\mathcal{B}(\boldsymbol{x}) \log \mathcal{B}(\boldsymbol{x})), \tag{5}
\end{equation*}
$$

where $\bar{F}$ is also called the free energy (following widely accepted physics terminology).
The exact variational formulation (5) is the starting point for approximate variational formulations, such as BP (Yedidia et al., 2005) and TRW (Wainwright and Jordan, 2007), stated solely in terms of the marginal beliefs associated with nodes and edges, respectively:

$$
\begin{align*}
& \forall a \in \mathcal{V}, \forall x_{a}: \mathcal{B}_{a}\left(x_{a}\right) \doteq \sum_{\boldsymbol{x} \backslash x_{a}} \mathcal{B}(\boldsymbol{x}),  \tag{6}\\
& \forall(a, b) \in \mathcal{E}, \forall x_{a}, x_{b}: \mathcal{B}_{a b}\left(x_{a}, x_{b}\right) \doteq \sum_{x \backslash\left(x_{a}, x_{b}\right)} \mathcal{B}(\boldsymbol{x}) . \tag{7}
\end{align*}
$$

Moreover, fractional approach developed in this manuscript provides variational formulation in terms of the marginal probabilities generalizing (and, in fact, interpolating between) respective BP and TRW approaches. Therefore, we now turn to stating the fractional variational formulation.

### 2.3 Fractional Variation Formulation

Let us introduce a fractional-, or $\lambda$ - reparametrization of the belief (proxy for the probability distribution of $\boldsymbol{x}$ )

$$
\begin{equation*}
\mathcal{B}^{(\lambda)}(\boldsymbol{x})=\frac{\prod_{\{a, b\} \in \mathcal{E}}\left(\mathcal{B}_{a b}\left(x_{a}, x_{b}\right)\right)^{\rho_{a b}^{(\lambda)}}}{\prod_{a \in \mathcal{V}}\left(\mathcal{B}_{a}\left(x_{a}\right)\right)^{\sum_{b \sim a} \rho_{a b}^{(\lambda)}-1}}, \tag{8}
\end{equation*}
$$

where $b \sim a$ is a shortcut notation for $b \in \mathcal{V}$ such that, given $a \in \mathcal{V},(a, b) \in \mathcal{E}$. Here in Eq. (8), $\rho_{a b}^{(\lambda)}$ is the $\lambda$-parameterized edge appearance probability

$$
\begin{equation*}
\rho_{a b}^{(\lambda)}=\rho_{a b}+\lambda\left(1-\rho_{a b}\right), \quad \lambda \in[0,1] . \tag{9}
\end{equation*}
$$

which is expressed via the $\lambda=0$ edge appearance probability, $\rho_{a b}$, dependent on the weighted set of the spanning trees, $\mathcal{T} \doteq\{T\}$, of the graph according to the following TRW rules (Wainwright and Jordan, 2007):

$$
\begin{equation*}
\forall(a, b) \in \mathcal{V}: \rho_{a b}=\sum_{T \in \mathcal{T}, \text { s.t. }(a, b) \in T} \rho_{T}, \sum_{T \in \mathcal{T}} \rho_{T}=1 \tag{10}
\end{equation*}
$$

A number of remarks are in order. First, $\lambda=1$ corresponds to the case of BP. Then Eq. (8) is exact in the case of a tree graph, but it can also be considered as a (loopy) BP approximation in general. Second, and as mentioned above, $\lambda=0$, corresponds to
the case of TRW. Third, the newly introduced (joint) beliefs is not globally consistent, i.e. $\sum_{\boldsymbol{x}} \mathcal{B}^{(\lambda)}(\boldsymbol{x}) \neq 1$ for any $\lambda$, including the $\lambda=0$ (TRW) and $\lambda=1$ (BP) cases.

Substituting Eq. (8) into Eq. (5) we arrive at the following fractional approximation to the exact free energy stated as an optimization over all the node and edge marginal beliefs, $\mathcal{B} \doteq\left(\mathcal{B}_{a b}\left(x_{a}, x_{b}\right) \mid \forall\{a, b\} \in \mathcal{E}, x_{a}, x_{b}= \pm 1\right) \cup\left(\mathcal{B}_{a}\left(x_{a}\right) \mid \forall a \in \mathcal{V}, x_{a}= \pm 1\right):$

$$
\begin{align*}
& \bar{F}^{(\lambda)} \doteq \min _{\mathcal{B} \in \mathcal{D}} F^{(\lambda)}(\mathcal{B}), F^{(\lambda)}(\mathcal{B}) \doteq E(\mathcal{B})-H^{(\lambda)}(\mathcal{B}),  \tag{11}\\
& E(\mathcal{B}) \doteq \sum_{(a, b) \in \mathcal{E}} \sum_{x_{a}, x_{b}= \pm 1} E_{a b}\left(x_{a}, x_{b}\right) \mathcal{B}_{a b}\left(x_{a}, x_{b}\right),  \tag{12}\\
& H^{(\lambda)}(\mathcal{B}) \doteq-\sum_{(a, b) \in \mathcal{E}} \rho_{a b}^{(\lambda)} \sum_{x_{a}, x_{b}= \pm 1} \mathcal{B}_{a b}\left(x_{a}, x_{b}\right) \log \mathcal{B}_{a b}\left(x_{a}, x_{b}\right) \\
&+\sum_{a \in \mathcal{V}}\left(\sum_{b \sim a} \rho_{a b}^{(\lambda)}-1\right) \sum_{x_{a}= \pm 1} \mathcal{B}_{a}\left(x_{a}\right) \log \mathcal{B}_{a}\left(x_{a}\right),  \tag{13}\\
& \mathcal{D} \doteq\left(\begin{array}{ll}
\mathcal{B}_{a}\left(x_{a}\right)=\sum_{x_{b}= \pm 1} \mathcal{B}_{a b}\left(x_{a}, x_{b}\right), \\
\forall a \in \mathcal{V}, \forall b \sim a, \forall x_{a}= \pm 1 ; & (a) \\
\mathcal{B}\left(\begin{array}{l}
\sum_{x_{a}, x_{b}= \pm 1} \mathcal{B}_{a b}\left(x_{a}, x_{b}\right)=1, \\
\forall(a, b) \in \mathcal{E} ; \\
\mathcal{B}_{a b}\left(x_{a}, x_{b}\right) \geq 0, \\
\forall(a, b) \in \mathcal{E}, \forall x_{a}, x_{b}= \pm 1 .
\end{array}\right. & (c)
\end{array}\right) \tag{14}
\end{align*}
$$

(As discussed in Section 3 in details, $\lambda=0$ results in $Z^{(\lambda)}$ which upper bounds the exact $Z$ and $\lambda=1$ results in the lower bound if the model is attractive.)

The optimization over beliefs in Eq. (11) can be restated in the Lagrangian form (see Appendix A.1). Fixed points of the Lagrangian (potentially many) satisfy the so-called message-passing equations (see Appendix A.2). Then, the fractional free energy (partition function) is given, consistently with all the formulas from the Appendices A.1, A.2, by

$$
\begin{align*}
& Z^{(\lambda)}=\exp \left(-\bar{F}^{(\lambda)}\right)=\exp \left(-F^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)\right)  \tag{15}\\
& =\prod_{\{a, b\} \in \mathcal{E}}\left(\sum_{x_{a}, x_{b}} \exp \left(-\frac{E_{a b}\left(x_{a}, x_{b}\right)}{\rho_{a b}^{(\lambda)}}\right) \times\right. \\
& \left.\left(\mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{\frac{\sum_{c a a} \rho_{a c}^{(\lambda)}-1}{\rho_{a b}^{(\lambda)}}}\left(\mu_{a \rightarrow b}^{(\lambda)}\left(x_{b}\right)\right)^{\frac{\sum_{c \sim b} \rho_{b c}^{(\lambda)}-1}{\rho_{a b}^{(\lambda)}}}\right)^{\rho_{a b}^{(\lambda)}} \times \prod_{a \in \mathcal{V}}\left(\sum_{x_{a}} \prod_{b \sim a} \mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{1-\sum_{c \sim a} \rho_{a c}^{(\lambda)}} .
\end{align*}
$$

## 3 Properties of the Fractional Free Energy

Given the construction of the fractional free energy, described above in Section 2.3 and also detailed in Appendix A, we are ready to make the following statements about the fractional free energy.

Theorem 1 [Monotonicity of the Fractional Free Energy] Assuming $\boldsymbol{\rho} \doteq\left(\rho_{a b} \mid(a, b) \in \mathcal{E}\right)$ is fixed, $\bar{F}^{(\lambda)}$ is a continuous, monotone function of $\lambda$.

Proof See Appendix B.

Theorem 2 [Concavity of the Fractional Free Energy] Assuming $\boldsymbol{\rho} \doteq\left(\rho_{a b} \mid(a, b) \in \mathcal{E}\right)$ is fixed, $\bar{F}^{(\lambda)}$ is a concave function of $\lambda$.
Proof According to Eq. (11) $\bar{F}^{(\lambda)}$ is a minimum (over beliefs) of the functions which are liner in $\lambda$, therfore the result is concave in $\lambda$. (The authors are grateful to an anonymous online reviewer for correcting what was an erroneous statement originally).

Notice that all the statements of this manuscript so far are made for an arbitrary Ising models, i.e. without any restrictions on the graph and vectors of the pair-wise interactions, $\boldsymbol{J}$ and singleton biases, $\boldsymbol{h}$. If the discussion is limited to attractive (ferromagnetic) Ising models, $\forall(a, b) \in \mathcal{E}: \quad J_{a b} \geq 0$, the following statement becomes a corollary of the Theorem 1
Lemma 3 [Exact Fractional] In the case of an attractive Ising model and any fixed $\boldsymbol{\rho}$ there exists $\lambda_{*} \in[0,1]$ such that, $Z^{\left(\lambda_{*}\right)}=Z$.
Proof Recall that by construction, $Z^{(\lambda=1)} \leq Z$, as proven in (Ruozzi, 2012). In words, the partition function computed within the Bethe (BP) approximation results in a lower bound to the exact partition function. On the other hand, we know from (Wainwright and Jordan, 2007), and also by construction, that $Z^{(\lambda=0)} \geq Z$, i.e. TRW estimate of the partition function provides an upper bound to the exact partition function. These lower and upper bounds, combined with the monotonicity of $Z^{(\lambda)}$ stated in Theorem 1 results in the desired statement.

## 4 Fractional Re-Parametrization for Exact Inference

Theorem 4 [Exact Relation Between $Z$ and $Z^{(\lambda)}$ ]

$$
\begin{align*}
Z & =Z^{(\lambda)} \mathcal{Z}^{(\lambda)},  \tag{16}\\
\mathcal{Z}^{(\lambda)} & \doteq \sum_{\boldsymbol{x}} \frac{\prod_{\{a, b\} \in \mathcal{E}}\left(\mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)\right)^{\rho_{a b}^{(\lambda)}}}{\prod_{a \in \mathcal{V}}\left(\mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)\right)^{\sum_{c \sim a} \rho_{a c}^{(\lambda)}-1}}=\mathbb{E}_{\boldsymbol{x} \sim p_{0}^{(\lambda)}(\cdot)}\left[\frac{\prod_{\{a, b\} \in \mathcal{E}}\left(\mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)\right)^{\rho_{a b}^{(\lambda)}}}{\prod_{a \in \mathcal{V}}\left(\mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)\right)^{\sum_{c \sim a} \rho_{a c}^{(\lambda)}}}\right], \tag{17}
\end{align*}
$$

where the fractional BP expression for the partition function, $Z^{(\lambda)}$, is defined in Eq. (15); $p_{0}^{(\lambda)}(\boldsymbol{x}) \doteq \prod_{a} \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)$ is the component-independent distribution devised from the FBPoptimal node-marginal probabilities.
Proof See Appendix C

Notice that $\mathcal{Z}^{(\lambda)}$, defined in Eq. (17), is the exact multiplicative correction term, expressed in terms of the FBP solution, which should be equal to 1 at the optimal value of $\lambda^{*}(J, H)$, which is achievable, according to Lemma 3 , in the case of the attractive Ising model.

## 5 Numerical Experiments

### 5.1 Setting, Use Cases and Methodology

In this Section we present results of our numerical experiments - supporting and also developing further theoretical results of the preceding Sections. Specifically, we will describe details of our experiments with the Ising model in the following "use cases:" (1) Over exemplary planar graph $-N \times N$ square grid, where $N=[3:: 25]$; (2) Over a fully connected graph, $K_{N}$, where $N=\left[3:: 8^{2}\right]$. The notation $[a:: b]$ indicates a range from a to b .

In both cases we consider attractive models and mixed models - that is the models with some interactions being attractive (ferromagnetic), $J_{a b}>0$, and some repulsive (antiferromagnetic), $J_{a b}<0$. We experiment with the zero-field case, $\boldsymbol{h}=0$, and also with the general (non-zero field) case. All of our models are "disordered" in the sense that we have generated samples of random $\boldsymbol{J}$ and $\boldsymbol{h}$. Specifically, in the attractive (mixed) case components of $\boldsymbol{J}$ are i.i.d. from the uniform distribution, $\mathcal{U}(0,1)(\mathcal{U}(-1,1))$, and components of $\boldsymbol{h}$ are i.i.d. from $\mathcal{U}(-1,1)$. In some of our experiments we draw a single instance of $\boldsymbol{J}$ and $\boldsymbol{h}$ from the respective ensemble. However, in other experiments - aimed at analysis of the variability within the respective ensemble - we show results for a number of instances.

We know that there is a big freedom in selecting a set of spanning trees and then re-weighting respective contributions to $\boldsymbol{\rho} \doteq\left(\rho_{a b} \mid(a, b) \in \mathcal{E}\right)$ according to Eq. (10). (See some discussion of the experiments with possible $\boldsymbol{\rho}$ in (Wainwright et al., 2005). However, we decided not to test the freedom, and instead, in all of our experiments $\rho$ is chosen unambiguously for a given graph uniformly. As shown in (Wainwright, 2002), the edgeuniform re-weighting is optimal, i.e. it provides the lowest TRW upper-bound, in the case of highly symmetric graphs, such as fully connected or double-periodic square grid. It was also assumed in the TRW literature (but to the best of our knowledge never proven) that the edge-uniform re-weighting is (almost always) possible. We clarify this point in the following statement.

Lemma 5 ([Edge-uniform Weights]) For any graph with all nodes of degree two or higher there exists a subset of spanning trees, such that each edge contributes at least one spanning tree, and the edge weight is calculated according to the edge-uniform rule: $\forall(a, b) \in \mathcal{V}$ : $\rho_{a b}=(|\mathcal{V}|-1) /|\mathcal{E}|$, where $|\mathcal{V}|$ is the number of vertices and $|\mathcal{E}|$ is the number of edges ${ }^{1}$.

Proof See Appendix D for constructive proof.

We introduce the Fractional Message Passing Algorithm, delineated as Algorithm 1, which calculates approximately the exact partition function for a specified Ising model on a graph $\mathcal{G}=(\mathcal{V}, \mathcal{E})$. This algorithm generalizes traditional message passing methods by interpolating between the Tree-Reweighted case $(\lambda=0)$ and the Belief Propagation case $(\lambda=1)$ for any $\lambda \in] 0,1[$. Utilizing Theorem 4, the algorithm identifies a particular value, denoted as $\lambda_{*}$, where the fractional partition function $Z^{\left(\lambda_{*}\right)}$ is approximately equal to the

[^1]```
Algorithm 1 Fractional Message Passing Algorithm
    Input: \(\mathcal{G}=(\mathcal{V}, \mathcal{E})\), graph.
    Initialize: \(\rho_{a b}=(|\mathcal{V}|-1) /|\mathcal{E}|,(\) lemma 5)
    For: \(\lambda=0.01: 0.05: 1\),
        1. Compute \(\rho_{a b}^{(\lambda)}=\rho_{a b}+\lambda\left(1-\rho_{a b}\right)\).
        2. Use TRW-BP to find \(Z^{(\lambda)}, \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right), \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)\)
        3. Compute \(\mathcal{Z}^{(\lambda)}\) utilizing Eq. (17).
```

## End

1. Find $\lambda_{*}$ where $\mathcal{Z}^{(\lambda)}=1$
2. Return $Z=Z^{\left(\lambda_{*}\right)}$
exact partition function $Z$. The algorithm employs Eq. (17) to determine the correction factor $\mathcal{Z}^{(\lambda)}$ utilizing fractional node and edge beliefs. Additionally, it uses Lemma 5 to initialize the edge appearance probabilities $\rho_{a b}$ uniformly.

To compute fractional free energy, $\bar{F}^{(\lambda)}$ (minus log of the fractional estimate for partition function), we generalize approach of (Bixler and Huang, 2018) which allows efficient, sparsematrix based, implementation. Our code will be made available at github upon acceptance of the paper.

To compare the fractional estimate $\bar{F}^{(\lambda)}=-\log Z^{(\lambda)}$, with the exact free energy, $\bar{F}=$ $-\log Z$, we either use direct computations (feasible for the $8 \times 8$ grid or smaller and for the fully connected graph over 64 nodes or smaller) or in the case of the planar grid and zero-field, when computation of the partition function is reduced to computing a determinant, we use the code from (Likhosherstov et al., 2019) (see also references therein). Our computations are done for the values of $\lambda$ equally spaced with the increment 0.05 , between 0.01 and 1 , $\lambda \in[0.01:: 0.05:: 1]$, $\lambda$ started from 0.01 instead of 0 , due to poor convergence issue near 0 . We use Eq. (27) to estimate $d \bar{F}^{(\lambda)} / d \lambda$, and then use finite difference approximation to estimate $d^{2} \bar{F}^{(\lambda)} / d \lambda^{2}$.

The $\log$-correction term, $\log \mathcal{Z}^{(\lambda)}=\log Z-\log Z^{(\lambda)}$, is estimated by direct sampling according to Eq. (17). (See Fig. (9) and respective discussion below for empirical analysis of the number of samples required to guarantee sufficient accuracy.)

It is important to stress that, even though the Fractional Message Passing Algorithm 1 is a direct extension of what was discussed in the literature in the past for the TRW $\lambda=0$ and $\mathrm{BP} \lambda=1$ cases, extending the algorithm to the interpolating $\lambda \in] 0,1[$ values is novel. In this regards, the $\lambda=0$ and $\lambda=1$ versions of the Fractional Message Passing Algorithm should be considered as providing baselines/benchmarks for performance of the Algorithm at the interpolating values of $\lambda$.

Figure 1: The case of the Ising Model (a) with non-zero field and random interaction, $h, J \sim \mathcal{U}(0,1)$ over $3 \times 3$ planar grid; and (b) with non-zero field and random interaction, $h, J \sim \mathcal{U}(0,1)$ over $K_{9}$ complete graph. We show fractional logpartition function (minus fractional free energy) - on the left- and the respective correction factor $\mathcal{Z}^{(\lambda)}$ - on the right vs the fractional parameter, $\lambda$. We observe monotonicity and concavity of $\bar{F}^{(\lambda)}$ on $\lambda$ and dependence of $\bar{F}^{(\lambda)}$ and $\log \mathcal{Z}^{(\lambda)}$ on $\lambda$ is relatively sharp (phase transition).

### 5.2 Properties of the Fractional Free Energy

We use Algorithm 1 for the fractional estimate of the log-partition function (minus fractional free energy), $\log Z^{(\lambda)}=-\bar{F}^{(\lambda)}$ and the $\log$ of the correction term, $\log \mathcal{Z}^{(\lambda)}=\log Z-\log Z^{(\lambda)}=$ $\bar{F}^{(\lambda)}-\bar{F}$, the results are shown as functions of $\lambda$ in Fig. (1) for the use cases described above. See also extended set of Figs. $(4,5,6.7)$ in the Appendix E, including dependence of $d \bar{F}^{(\lambda)} / d \lambda, d^{2} \bar{F}^{(\lambda)} / d \lambda^{2}$ on $\lambda$. We draw from this set of Figures the following empirical conclusions:

- The monotonicity and concavity of $\bar{F}^{(\lambda)}$, proven in Theorem 1 and Theorem 2, respectively, are confirmed.
- Dependence of $\bar{F}^{(\lambda)}$ and $\log \mathcal{Z}^{(\lambda)}$ on $\lambda$ is relatively sharp - of a phase transition type at some $\bar{\lambda}$, when we move from TRW regime at $\lambda<\bar{\lambda}$ to BP regime at $\lambda>\bar{\lambda}$. Notice that estimate of the threshold, $\bar{\lambda}$, decreases with the growth in $N$.

### 5.3 Relation between Exact and Fractional

Figs. (45, 67 ), shown in the Appendix E, also give an empirical confirmation to the Lemma 3 statement in the part which concerns independence of, $Z^{(\lambda)} \mathcal{Z}^{(\lambda)}$, of $\lambda$. This observation, combined with the full statement of the Lemma 3, suggests that if two or more of empirical estimates of $Z^{(\lambda)} \mathcal{Z}^{(\lambda)}$ at different $\lambda$ are sufficiently close to each other we can use them to bound $Z$ from above and below. Moreover, the full statement of the Theorem 4, i.e. equality between the left- and right- hand sides of Eq. (16), is also confirmed in all of our simulations with high accuracy (when we can verify it by computing $Z$ directly).

Figure 2: Planar zero-field Ising models for $n \times n$ grid with $J \sim \mathcal{U}(0,1)$. For each $n$ four different instances are generated by sampling uniformly at random from the unit interval and the exact values are shown by hollow marker on each graph. (a) $10 \times 10$ (b) $20 \times 20$ (c) $30 \times 30$ (d) $40 \times 40$. Open symbols show respective values of $\lambda_{*}$.

### 5.4 Concentration of the Fractional Parameter in Large Ensembles

Fig. (8) in the Appendix E shows dependence of $\bar{F}^{(\lambda)}$ on the fractional parameter, $\lambda$, for a number of instances drawn from two exemplary attractive use-case ensembles. We observe that variability in the value of $\bar{F}^{(\lambda)}$ is sufficiently large. Variability of $\lambda_{*}$, where $Z^{\left(\lambda_{*}\right)}=Z$, are also observed, even though it is significantly smaller.

The last observation suggests that variability of $\lambda_{*}$ within an attractive ensemble decreases with $N$ when it grows. This guess is confirmed in our experiments with larger attractive ensembles illustrated in Fig. (2) for different $N$. For each $N$ in the case over $N \times N$ grid we generate 4 different instances. We observe that as $N$ increases variability of $\lambda_{*}$ within the ensemble decreases dramatically. This observation is quite remarkable, as it suggests that it is enough to estimate $\lambda_{*}$ for one instance in a large ensemble and then use it for accurate estimation of $Z$ by simply computing $Z^{\left(\lambda_{*}\right)}$. Our estimations, based on the data shown in Fig. (2) and other similar experiments (not shown) suggest that the width of the probability distribution of $\lambda_{*}$ within the ensemble scales as $\propto 1 / \sqrt{N}$ with increase in $N$.

### 5.5 Convergence of Sampling for Fractional Partition Function

Fig. (9), shown in the Appendix E, reports dependence of the sample-based estimate of $\mathcal{Z}^{(\lambda)}$ on the number of samples. Our major observation here is that the result converges with increase in the number of samples. Moreover, comparing the speed of convergence (with the number of samples) on the size of the system, $N$, we estimate that number of samples needed for convergence scales as $\mathcal{O}\left(N^{[2:: 4]}\right)$.

### 5.6 Fractional Approach for Mixed (attractive and repulsive) Cases

Fig. (10) of the Appendix E, shows two distinct situations which may be observed in the mixed case where some of the interactions are attractive but other are repulsive, then allowing $Z^{(\lambda)}$ to be smaller or larger than $Z$. The former case is akin to the attractive model and $\lambda_{*} \in[0,1]$, while in the later case there exists no $\lambda_{*} \in[0,1]$ such that $Z^{\left(\lambda_{*}\right)}=Z$.

## 6 Conclusions and Path Forward

This manuscript suggests a new promising approach to evaluating inference in Ising Models. The approach consists in, first, solving a fractional variational problem via a distributed message-passing algorithm resulting in the fractional estimations for the partition function and marginal beliefs. We then compute multiplicative correction to the fractional partition function by evaluating a well-defined expectation of the mean-field probability distribution both constructed explicitly from the marginal beliefs. We showed that the freedom in the fractional parameter is useful, e.g. for finding optimal value of the parameter, $\lambda_{*}$, where the multipicative correction is unity. Our theory validated experiments result in a number of interesting observations, such as a phase-transition like dependence of the fractional free-energy on $\lambda$ and strong suppression of fluctuations of $\lambda_{*}$ in large ensembles.

As a path-forward we envision extending this fractional approach along the following directions:

- Proving or disproving the concentration conjecture and small number of samples conjecture, made informally in Section 5.4 and Section 5.5, respectively.
- Generalizing the extrapolation technique, e.g. building a scheme interpolating between TRW and Mean-Field. This will be of special interest for the case of the mixed ensembles which are generally out of reach of the fractional approach (between TRW and BP ) presented in the manuscript.
- Generalizing the extrapolation technique to a more general class of Graphical Models.

We also anticipate that all of these developments, presented in this manuscript and others to follow, will help to make variational GM techniques competitive with other, and admittedly more popular, methods of Machine Learning, such as Deep Learning (DL). We envision seeing in the future more examples where the variational GM techniques will be reinforced with the automatic differentiation, e.g. in the spirit of (Lucibello et al., 2022), and also integrated into modern Deep Learning protocols, e.g. as discussed in (Garcia Satorras and Welling, 2021).

## Appendix A. Fractional Variational Formulation: Details

## A. 1 Lagrangian formulation

Introducing Lagrangian multipliers associated with the linear constraints in Eqs. (14a.14b) we arrive at the following Lagrangian reformulation of Eq. (11)

$$
\begin{align*}
\bar{F}^{(\lambda)}= & \min _{\mathcal{B} \geq 0} \max _{\boldsymbol{\eta}, \boldsymbol{\psi}} L^{(\lambda)}(\mathcal{B} ; \boldsymbol{\eta}, \boldsymbol{\psi}), \quad L^{(\lambda)} \doteq F^{(\lambda)}(\mathcal{B})+  \tag{18}\\
& \sum_{a \in \mathcal{V} ; b \sim a} \sum_{x_{a}} \eta_{b \rightarrow a}\left(x_{a}\right)\left(\sum_{x_{b}} \mathcal{B}_{a b}\left(x_{a}, x_{b}\right)-\mathcal{B}_{a}\left(x_{a}\right)\right)+\sum_{\{a, b\} \in \mathcal{E}} \psi_{a b}\left(1-\sum_{x_{a}, x_{b}} \mathcal{B}_{a b}\left(x_{a}, x_{b}\right)\right)
\end{align*}
$$

where $L^{(\lambda)}(\mathcal{B} ; \boldsymbol{\eta}, \boldsymbol{\psi})$ is the (extended) Lagrangian dependent on both the primary variables (beliefs, $\mathcal{B}$ ) and the newly introduced dual variables, $\boldsymbol{\eta} \doteq\left(\eta_{b \rightarrow a}\left(x_{a}\right) \in \mathbb{R} \mid \forall a \in \mathcal{V}, \forall b \sim\right.$ $\left.a, \forall x_{a}= \pm 1\right)$ and $\boldsymbol{\psi} \doteq\left(\psi_{a} \in \mathbb{R} \mid \forall a \in \mathcal{V}\right)$. Stationary point of the Lagrangian (18), assuming that it is unique, is defined by the following system of equations

$$
\begin{align*}
& \forall\{a, b\} \in \mathcal{E}, \forall x_{a}, x_{b}= \pm 1: \quad \frac{\delta L^{(\lambda)}(\mathcal{B})}{\delta \mathcal{B}_{a b}\left(x_{a}, x_{b}\right)}=0 \Rightarrow E_{a b}\left(x_{a}, x_{b}\right)+  \tag{19}\\
& \rho_{a b}^{(\lambda)}\left(\log \left(\mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)\right)+1\right)-\psi_{a b}^{(\lambda)}+\eta_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)+\eta_{a \rightarrow b}^{(\lambda)}\left(x_{b}\right)=0 \\
& \forall a \in \mathcal{V}, \forall x_{a}= \pm 1: \frac{\delta L^{(\lambda)}(\mathcal{B})}{\delta \mathcal{B}_{a}\left(x_{a}\right)}=0 \Rightarrow\left(\sum_{b \sim a} \rho_{a b}^{(\lambda)}-1\right)\left(\log \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)+1\right) \\
& \quad+\sum_{b \sim a} \eta_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)=0 \tag{20}
\end{align*}
$$

augmented with Eqs. (14a:14b). Eqs. (19) and Eqs. (20) results in the following expressions for the marginals in terms of the Lagrangian multipliers

$$
\begin{align*}
& \forall a \in \mathcal{V}, \forall x_{a}= \pm 1: \quad \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right) \propto \exp \left(-\frac{\sum_{b \sim a} \eta_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)}{\sum_{b \sim a} \rho_{a b}^{(\lambda)}-1}\right),  \tag{21}\\
& \forall\{a, b\} \in \mathcal{E}, \forall x_{a}, x_{b}= \pm 1: \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right) \propto \exp \left(-\frac{E_{a b}\left(x_{a}, x_{b}\right)+\eta_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)_{a \rightarrow b}^{(\lambda)}\left(x_{b}\right)}{\rho_{a b}^{(\lambda)}}\right) . \tag{22}
\end{align*}
$$

Here in Eqs. (19:20 2122 ) and below the upper index $(\lambda)$ in $\mathcal{B}^{(\lambda)}, \eta^{(\lambda)}$ and $\psi^{(\lambda)}$ variables indicates that the respective variables are optimal, i.e. argmax and argmin, over respective optimizations in Eq. (18).

## A. 2 Message Passing

We may also rewrite Eqs. (21 22) in terms of the so-called message (from node-to-node) variables. Then the marginal beliefs are expressed via the $\mu^{(\lambda)}$-messages according to

$$
\begin{align*}
& \forall a \in \mathcal{V}, \forall b \sim a: \mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right) \doteq \exp \left(-\frac{\eta_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)}{\sum_{b \sim a} \rho_{a b}^{(\lambda)}-1}\right),  \tag{23}\\
& \forall a \in \mathcal{V}, \forall x_{a}= \pm 1: \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)=\frac{\prod_{b \sim a} \mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)}{\sum_{x_{a}} \prod_{b \sim a} \mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)},  \tag{24}\\
& \forall\{a, b\} \in \mathcal{E}, \forall x_{a}, x_{b}= \pm 1: \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)  \tag{25}\\
& =\frac{\exp \left(-\frac{E_{a b}\left(x_{a}, x_{b}\right)}{\rho_{a b}^{(\lambda)}}\right)\left(\mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{\frac{\sum_{a, a} \rho_{a c}^{(\lambda)}-1}{\rho_{a b}^{(\lambda)}}}\left(\mu_{a \rightarrow b}^{(\lambda)}\left(x_{b}\right)\right)^{\frac{\sum_{c \sim b} \rho_{b c}^{(\lambda)}-1}{\rho_{a b}^{(\lambda)}}}}{\sum_{x_{a}, x_{b}} \exp \left(-\frac{E_{a b}\left(x_{a}, x_{b}\right)}{\rho_{a b}^{(\lambda)}}\right)\left(\mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{\frac{\sum_{a b a}^{(\lambda)}}{\rho_{a c}^{(\lambda)}-1}}\left(\mu_{a \rightarrow b}^{(\lambda)}\left(x_{b}\right)\right)^{\frac{\sum_{c \sim b} \rho_{b c}^{(\lambda)}-1}{\rho_{a b}}}},
\end{align*}
$$

and the Fractional Belief Propagation (FBP) equations, expressing relations between pairwise and singleton marginals become:

$$
\left.\begin{array}{l}
\forall a \in \mathcal{V}, \forall b \sim a, \forall x_{a}= \pm 1: \quad \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right) \propto \prod_{b \sim a} \mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)  \tag{26}\\
\propto \sum_{x_{b}} \exp \left(-\frac{E_{a b}\left(x_{a}, x_{b}\right)}{\rho_{a b}^{(\lambda)}}\right)\left(\mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{\frac{\sum_{c a} \rho_{a c}(\lambda)}{\rho_{a b}}} \rho_{a b}^{(\lambda)}
\end{array} \mu_{a \rightarrow b}^{(\lambda)}\left(x_{b}\right)\right)^{\frac{\sum_{c \sim b} \rho_{b c}^{(\lambda)}-1}{\rho_{a b}^{(\lambda)}}} \propto \sum_{x_{b}} \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right) . . ~ \$
$$

Note (on a tangent), that the $\mu^{(\lambda)}$-(message) variables introduced here are related but not equivalent to the $M^{(\lambda)}$-messages which can also be seen used in the BP-literature, see e.g. Section 4.1.3 of (Wainwright and Jordan, 2007). Specifically in the case of BP, i.e. when $\rho_{a b}^{(\lambda)}=1$, relation between $\mu^{(\lambda)}$ and $M^{(\lambda)}$ variables is as follows, $\left(\mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{d_{a}-1}=$ $\prod_{c \sim a ; c \neq b} M_{c \rightarrow a}^{(\lambda)}\left(x_{a}\right)$.

## Appendix B. Proof of Theorem 1

Let us evaluate derivative of the fractional free energy (11) over $\lambda$ explicitly

$$
\begin{aligned}
\frac{d}{d \lambda} \bar{F}^{(\lambda)} & =\frac{d}{d \lambda} F^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)=\sum_{\{a, b\}} \sum_{x_{a}, x_{b}} \frac{\partial F^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)}{\partial \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)} \frac{d \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)}{d \lambda} \\
& +\sum_{a} \sum_{x_{a}} \frac{\partial F^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)}{\partial \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)} \frac{d \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)}{d \lambda}-\sum_{\{a, b\}} \frac{\partial H^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)}{\partial \rho_{a b}^{(\lambda)}} \frac{d \rho_{a b}^{(\lambda)}}{d \lambda} .
\end{aligned}
$$

Taking into account for the conditions of stationarity of the fractional free energy, tracking explicit dependencies of the fractional entropy on $\rho_{a b}^{(\lambda)}$, and thus on $\lambda$, we arrive at

$$
\begin{aligned}
\forall\{a, b\}: \quad & \frac{\partial F^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)}{\partial \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)}=0 ; \quad \forall a: \quad \frac{\partial F^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)}{\partial \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)}=0 \\
\frac{\partial H^{(\lambda)}\left(\mathcal{B}^{(\lambda)}\right)}{\partial \rho_{a b}^{(\lambda)}}= & -\sum_{x_{a}, x_{b}= \pm 1} \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right) \log \mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)+\sum_{x_{a}= \pm 1} \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right) \log \mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right) \\
& +\sum_{x_{b}= \pm 1} \mathcal{B}_{b}^{(\lambda)}\left(x_{b}\right) \log \mathcal{B}_{b}^{(\lambda)}\left(x_{b}\right)=-I_{a b}^{(\lambda)},
\end{aligned}
$$

where the newly introduced $I_{a b}^{(\lambda)}$ is nothing but the pairwise mutual information defined according to $\mathcal{B}^{(\lambda)}$. Notice that $I_{a b}^{(\lambda)} \geq 0$. Since, $d \rho_{a b}^{(\lambda)} / d \lambda=1-\rho_{a b} \geq 0$, and summarizing all of the above we derive

$$
\begin{equation*}
\frac{d}{d \lambda} \bar{F}^{(\lambda)}=-\sum_{\{a, b\}}\left(1-\rho_{a b}\right) I_{a b}^{(\lambda)} \leq 0 \tag{27}
\end{equation*}
$$

therefore concluding proof of both continuity (the derivative is bounded) and monotonicity (the derivative is negative).

## Appendix C. Proof of Theorem 4

Consistently with Eq. (8), Eqs. (24 25) allow us to rewrite the joint probability distribution in terms of the optimal beliefs which solve the fractional Eqs. (26)

$$
\begin{align*}
& p(\boldsymbol{x})=Z^{-1} \prod_{\{a, b\} \in \mathcal{E}}\left(\sum_{x_{a}, x_{b}} \exp \left(-\frac{E_{a b}\left(x_{a}, x_{b}\right)}{\rho_{a b}^{(\lambda)}}\right)\left(\mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{\frac{\sum_{c \sim a} \rho_{a c}^{(\lambda)}-1}{\rho_{a b}^{(\lambda)}}}\left(\mu_{a \rightarrow b}^{(\lambda)}\left(x_{b}\right)\right)^{\frac{\sum_{c \sim b} \rho_{b c}^{(\lambda)}-1}{\rho_{a b}^{(\lambda)}}}\right)^{\rho_{a b}^{(\lambda)}} \times \\
& \prod_{a \in \mathcal{V}}\left(\sum_{x_{a}} \prod_{b \sim a} \mu_{b \rightarrow a}^{(\lambda)}\left(x_{a}\right)\right)^{\sum_{c \sim a} \rho_{a c}^{(\lambda)}-1} \prod_{\{a, b\} \in \mathcal{E}}\left(\mathcal{B}_{a b}^{(\lambda)}\left(x_{a}, x_{b}\right)\right)^{\rho_{a b}^{(\lambda)}}  \tag{28}\\
& \prod_{a \in \mathcal{V}}\left(\mathcal{B}_{a}^{(\lambda)}\left(x_{a}\right)\right)_{c \sim a}^{\sum_{c \sim} \rho_{a c}^{(\lambda)}-1}
\end{align*}
$$

Normalization condition, that is the requirement for the sum on the right hand side of Eq. (28) to return 1, results in the desired statement, i.e. Eqs. (16 17).

## Appendix D. Proof of Lemma 5

Our proof of the statement is constructive and it is thus formalized in the Algorithm 2. The Algorithm follows induction, starting from a complete graph and then progressing by removing edges (and therefore loops) sequentially, such that at any step all nodes continue to be of degree two or larger. The induction terminates when the resulting graph is a single loop. See Fig. (3) for an illustration on the example of $N=4$, thus $K_{4}$.

Figure 3: Construction of the set of spanning trees for a sequence of graphs built from the $K_{4}$ graph (sub-figure (a)) in two steps, from (a) to (b) and from (b) to (c), each time eliminating an edge. At each step we remove one edge (shown dashed green), remove one spanning tree (shown circled and crossed red), and add a new edge (shown solid green) to all the remaining spanning trees which lost an edge such that they stay spanning trees and the resulting $\rho_{a b}$ edges are uniform among the remaining spanning trees. The resulting number of spanning trees and the uniform edge weights are (a) $|V|=4$ and $\forall(a, b) \in \mathcal{V}, \rho_{a b}=|\mathcal{V}|-1 /|\mathcal{E}|=(4-1) / 6=$ $3 / 6=1 / 2$; (b) $|V|=5$ and $\forall(a, b) \in \mathcal{V},|\mathcal{V}|-1 /|\mathcal{E}|=(4-1) / 5=3 / 5 ;(\mathrm{c})|V|=4$ and $\forall(a, b) \in \mathcal{V},|\mathcal{V}|-1 /|\mathcal{E}|=(4-1) / 4=3 / 4$.

The proof allows to construct the required set of spanning trees for any graph (with all nodes of degree two or larger) because by selecting a sequence of edges in the Algorithm 2 properly we can arrive at the given graph starting from the complete graph containing as many nodes as the given graph and eliminating edges according to the Algorithm 2.

## Appendix E. More Figures from Numerical Experiments

We show in this Appendix an extended set of Figures for the experiments discussed in the Section 5.3 of the main text. Specifically, results of our experiment for the case of the Ising model over planar graphs and complete graphs of various sizes in the settings of zero- and non-zero- fields are illustrated in Figs. (45, 67 ). We show in this set of figures dependence of $\log Z^{(\lambda)}=-\bar{F}^{(\lambda)}$ and $\log \mathcal{Z}^{(\lambda)}$, as well as $d \bar{F}^{(\lambda)} / d \lambda$ and $d^{2} \bar{F}^{(\lambda)} / d \lambda^{2}$, on $\lambda$. Observing dependence of the first and second derivatives of the fractional free energy on $\lambda$ allows us to conclude (confirm) that the log fractional partition function is monotone decreasing and also convex in $\lambda$. We also observe that when $\lambda$ is sufficiently large, $\log Z^{(\lambda)}$ is independent of $\lambda$. We also track in these figures the value of $\lambda_{*}$, correspondent to $\mathcal{Z}^{\left(\lambda_{*}\right)}=1$, and thus $Z=Z^{\left(\lambda_{*}\right)}$.

Fig. (8), mentioned in Section 5.4 shows $\lambda_{*}$ for a number of instances drawn from the respective ensembles of the Ising model (over planar and complete graphs). We observe that in the planar case, $\lambda_{*} \in[0.25,0.45]$, while in the case of the complete graph, $\lambda_{*} \in[0.05,0.15]$.

Fig. (9), mentioned in Section 5.5, shows results for the experiments with the Ising model of two different sizes. We see here estimation of the correction factor, $\log \mathcal{Z}^{(\lambda)}$, evaluated at different $\lambda$ for a varying number of samples (drawn i.i.d. from the mean-field distribution built based of the fractional nodal beliefs). We observe that the estimate stops to change

```
Algorithm 2 Edge-Uniform Set of Spanning Trees
    Input: \(K_{N}\), graph. Sequence of edges, \(\left\{e_{1}, \cdots, e_{N-2}\right\}\) of \(K_{N}\) and respective sequence of
    graphs, \(\left\{\mathcal{G}_{1}, \cdots, \mathcal{G}_{N-2}\right\}\), such that, \(\mathcal{G}_{1}=K_{N} \backslash e_{1}, \forall n=1, \cdots, N-3: \mathcal{G}_{n+1} \doteq \mathcal{G}_{n} \backslash e_{n+1}\),
    and \(\mathcal{G}_{N-2}\) is a single loop
    Initialize: \(\mathcal{T}\) - set of all linear spanning trees of \(\mathcal{G}\). (A spanning tree is linear if all nodes
    is of degree two or one.)
    Repeat: \(n=1, \cdots\)
        1. \(\mathcal{G}=(\mathcal{V}, \mathcal{E})=\mathcal{G}_{n}\)
        2. \(\forall T \in \mathcal{T}: \rho_{T}=1 /|\mathcal{E}|\) and thus \(\forall(a, b) \in \mathcal{E}: \rho_{a b}=(|\mathcal{V}|-1) /|\mathcal{E}|\).
        3. Exit if \(n=N-2\).
        4. Remove edge \(e_{n}\) from all spanning trees in \(\mathcal{T}\)
        5. \(\mathcal{T} \leftarrow \mathcal{T} \backslash\) (element of \(\mathcal{T}\) which becomes disconnected)
        6. Modify \(\mathcal{T}\) by adding an extra edge to each spanning tree of \(\mathcal{T}\) having ( \(N-n-1\) )
        edges. These added edges should keep each element of \(\mathcal{T}\) a spanning tree of \(\mathcal{G}\) and
        also guarantee that each edge enters exactly \(N-1\) resulting spanning trees. (It is
        straightforward to check that such a construction is unique and unambiguous. See
        Fig. (3) for illustration.)
```

with increase in the number of samples, once a sufficient number of samples, $M_{c}$, is drawn. We estimate that $M_{c}$ grows with $N$ as $\mathcal{O}\left(N^{4}\right)$ or slower.

Fig. (10), mentioned in Section 5.6, shows results for the mix case when the pair-wise interaction can vary in sign from edge to edge. In this mixed case, as seen in the presented examples, we can not guarantee that BP provides a lower bound on the partition function, and thus $\lambda_{*}$ may or may not be identified within the $[0,1]$ interval.

Figure 4: The case of the Ising Model with non-zero magnetic field and random interaction, $h, J \sim \mathcal{U}(0,1)$ over $3 \times 3$ planar grid. We show (a) fractional log-partition function (minus fractional free energy) - on the left- and the respective correction factor $\mathcal{Z}^{(\lambda)}$ - on the right vs the fractional parameter, $\lambda$; (b) the first order derivative on the left - and second order derivative - on the right - vs $\lambda$.

Figure 5: The case of the Ising Model with zero magnetic field and random interaction, $J \sim \mathcal{U}(0,1)$ over $3 \times 3$ planar grid. Further details are identical to used in Fig. (4).

Figure 8: $F^{(\lambda)}$ vs $\lambda$ for a number of instances (shown in different colors) drawn for the Ising model ensembles over, (a) $3 \times 3$ grid, and (b) $K_{9}$ graph, where elements of $\boldsymbol{J}$ and $\boldsymbol{h}$ are i.i.d. from $\mathcal{U}(0,1)$. Circles mark respective exact values, $\lambda_{*}$.

Figure 9: Dependence of the sample-based estimate of $\mathcal{Z}^{(\lambda)}$ on the number of samples in the case of attractive Ising model over (a) $3 \times 3$, and (b) $6 \times 6$ grids, where elements of $\boldsymbol{J}$ and $\boldsymbol{h}$ are drawn i.i.d. from $\mathcal{U}[0,1]$. Different colors correspond to different values of $\lambda$.

[^1]:    1. The "degree two or higher" constraint on nodes is not restrictive, because we can either eliminate nodes with degree one (and also tree-like branches associated with them) by direct summation, or alternatively include the tree like branches in the appropriate number of spanning trees constructed for the graph ignoring the tree-like branches.
