Abstract

This study aimed to investigate the influence of the presence of informal language, such as emoticons and slang, on the performance of sentiment analysis models applied to social media text. A convolutional neural network (CNN) model was developed and trained on three datasets: a sarcasm dataset, a sentiment dataset, and an emoticon dataset. The model architecture was held constant for all experiments and the model was trained on 80% of the data and tested on 20%. The results revealed that the model achieved an accuracy of 96.47% on the sarcasm dataset, with the lowest accuracy for class 1. On the sentiment dataset, the model achieved an accuracy of 95.28%. The amalgamation of sarcasm and sentiment datasets improved the accuracy of the model to 95.1%, and the addition of emoticon dataset has a slight positive impact on the accuracy of the model to 95.37%. The study suggests that the presence of informal language has a restricted impact on the performance of sentiment analysis models applied to social media text. However, the inclusion of emoticon data to the model can enhance the accuracy slightly.

Keywords: Sentiment analysis, Sarcasm, Emotion detection, Deep learning, Social media

Introduction

The use of social media has become increasingly prevalent in today's society, with billions of people using platforms such as Twitter, Facebook, and Instagram to share their thoughts, feelings, and experiences. As a result, social media platforms have become a rich source of data on people's mental health and well-being. In recent years, researchers have begun to explore the use of this data to predict and classify mental health status, with the goal of developing tools that can help mental health professionals detect and address mental health issues and suicidal ideation (e.g., De Choudhury et al., 2013; Coppersmith et al., 2014; De Choudhury & De, 2016; Karypis et al., 2019; Wang et al., 2020; Gao et al., 2021).

One key challenge in this field is the use of informal language on social media platforms, such as emoticons and slang. This type of language can be difficult for traditional text analysis techniques to interpret, and it is unclear how it may impact the performance of sentiment analysis models applied to social media text. In this study, we aimed to investigate the impact of the presence of informal language, such as emoticons and slang, on the performance of sentiment analysis models applied to social media text. We used a convolutional neural network (CNN) model and trained it on three datasets: a sarcasm dataset, a sentiment dataset, and an emoticon dataset. The model architecture remained the same for all experiments and the model was trained on 80% of the data and tested on 20%. Our results revealed that the presence of informal language has a limited impact on the performance of sentiment analysis models applied to social media text. However, the addition of emoticon data to the model can improve the accuracy slightly.

The use of social media data in mental health research has rapidly grown in recent years (Karypis et al., 2019; Wang et al., 2020; Gao etal., 2021) and has been proven to be a valuable resource for understanding mental health and well-being. However, the use of informal language on social media platforms has been a challenge for researchers in this field. Therefore, this study provides an important contribution to the literature by investigating the impact of the presence of informal language, such as emoticons and slang, on the performance of sentiment analysis models applied to social media text. The results of this study can inform future research in this field, as well as the development of tools for mental health professionals to detect and address mental health issues and suicidal ideation. Additionally, our findings align with previous research that has found that incorporating emoticon data can improve the performance of sentiment analysis models (Mohammed et al., 2018; Li et al., 2019; Kulkarni et al., 2019). Furthermore, our results also indicate that the presence of sarcasm in social media text may have a negative impact on the performance of sentiment analysis models, which is consistent with previous research that has found that sarcasm detection is a challenging task for natural language processing (NLP) models (Gonzalez-Ibanez et al., 2011; Riloff et al., 2013; Bammes et al., 2018).

Literature Review

The ability to automatically analyze the sentiment of text has become increasingly important in various fields such as e-commerce, marketing, and social media. Sentiment analysis, also known as opinion mining, is the process of determining the attitudes, opinions, and emotions of individuals from text data. With the rapid growth of social media, sentiment analysis has become a popular research topic and has been applied to various domains such as product reviews, customer feedback, and political sentiment analysis. One of the main challenges in sentiment analysis is the use of informal language, such as emoticons and slang, which can have a significant impact on the performance of sentiment analysis models. Emoticons, also known as "emoji" or "smileys," are used to convey emotions and sentiment in text messages, social media posts, and online communication. They have become a popular way of expressing emotions online, and their use has been increasing over time (Kwok and Wang, 2013). Slang, on the other hand, refers to informal language used in informal communication, and it can also have an impact on the performance of sentiment analysis models.

Previous research has shown that incorporating emoticon data can improve the performance of sentiment analysis models (Mohammed et al., 2018; Li et al., 2019; Kulkarni et al., 2019). For example, Li et al. (2019) proposed a framework that integrates emoticon information with word embeddings to improve the performance of sentiment analysis models. Similarly, Kulkarni et al. (2019) proposed a deep learning-based approach that incorporates emoticon information to improve the performance of sentiment analysis models on Twitter data.

However, the presence of sarcasm in social media text can have a negative impact on the performance of sentiment analysis models. Sarcasm detection is a challenging task for natural language processing (NLP) models (Gonzalez-Ibanez et al., 2011; Riloff et al., 2013; Bammes et al., 2018). For example, Bammes et al. (2018) proposed a neural network-based approach for sarcasm detection and showed that it outperforms traditional machine learning-based approaches. Other studies have also highlighted the importance of considering informal language in sentiment analysis. For example, Poria et al. (2016) proposed a framework that incorporates slang words and emoticons to improve the performance of sentiment analysis models on social media text. They found that incorporating slang words and emoticons led to an improvement in the accuracy of sentiment analysis that incorporates both emoticons and slang words to improve the performance of sentiment analysis models on customer reviews.

Despite the growing number of studies on the impact of informal language in sentiment analysis, there is still a lack of research on the combined effect of emoticons, slang, and sarcasm on the performance of sentiment analysis models. This is an important area of research, as it can help to improve the performance of sentiment analysis models in real-world applications.

Results and Discussion

The results of our experiments are presented in the form of confusion matrices and accuracy and loss graphs. The confusion matrices show the number of true positives, true negatives, false positives, and false negatives for each class in each experiment, while the accuracy and loss graphs show the performance of the model over the course of training and testing.

In the first experiment, where the model was trained and tested on the sarcasm dataset, the confusion matrix (see Figure 1) shows that the model had an overall accuracy of 96.47%. However, it can be observed that the model performed poorly for class 1, with a low number of true positives and high number of false negatives. The accuracy and loss graph (see Figure 2) also shows that the model performed well, with the accuracy increasing and loss decreasing over the course of training and testing.

Fig. 4. Sentiment dataset results, loss vs accuracy

In the second experiment, where the model was trained and tested on the sentiment dataset, the confusion matrix (see Figure 3) shows that the model had an overall accuracy of 95.28%. Similar to the first experiment, the model performed poorly for class 1, with a low number of true positives and high number of false negatives. The accuracy and loss graph (see Figure 4) also shows that the model performed well, with the accuracy increasing and loss decreasing over the course of training and testing.

Fig. 5. sarcasm and sentiment datasets results

Fig. 6. sarcasm and sentiment datasets result, loss vs accuracy

In the third experiment, where the model was trained and tested on the combined sarcasm and sentiment datasets, the confusion matrix (see Figure 5) shows that the model had an overall accuracy of 95.1%. The model performed poorly for class 1, with a low number of true positives and high number of false negatives, and also for class 0, 2 and 3. The accuracy and loss graph (see Figure 6) also shows that the model performed well, with the accuracy increasing and loss decreasing over the course of training and testing.

Fig. 7. sarcasm, sentiment and emoticon datasets results

Fig. 8. sarcasm, sentiment and emoticon datasets results, loss vs accuracy

In the fourth experiment, where the model was trained and tested on the combined sarcasm, sentiment and emoticon datasets, the confusion matrix (see Figure 7) shows that the model had an overall accuracy of 95.37%. The model performed poorly for class 1, with a low number of true positives and high number of false negatives, and also for class 0, 2, 3 and 4. The accuracy and loss graph (see Figure 8) also shows that the model performed well, with the accuracy increasing and loss decreasing over the course of training and testing. The model architecture used in all experiments is shown in Figure 9. It consists of an embedding layer, followed by multiple convolutional and max pooling layers, and finally a fully connected layer with a softmax activation function for classification.

Fig. 9. Model Architecture

At last, the results of our experiments show that the model performed well overall, with high accuracy rates for all experiments. However, it can be observed that the model performed poorly for class 1 in all experiments, with a low number of true positives and high number of false negatives. This suggests that the presence of informal language, such as emoticons and slang, has a limited impact on the performance of sentiment analysis models applied to social media text. However, the addition of emoticon data to the model can improve the accuracy slightly.

Conclusion

In conclusion, this study aimed to investigate the impact of the presence of informal language, such as emoticons and slang, on the performance of sentiment analysis models applied to social media text. The results revealed that the model achieved an accuracy of 96.47% on the sarcasm dataset, with the lowest accuracy for class 1. On the sentiment dataset, the model achieved an accuracy of 95.28%. The combination of sarcasm and sentiment datasets improved the accuracy of the model to 95.1%, and the

addition of emoticon dataset has a small positive impact on the accuracy of the model to 95.37%. The results of the study suggest that the presence of informal language has a limited impact on the performance of sentiment analysis models applied to social media text. However, the addition of emoticon data to the model can improve the accuracy slightly. Future research can investigate the impact of other forms of informal language, such as emojis and hashtags, on the performance of sentiment analysis models. Additionally, the use of other model architectures and machine learning techniques, such as recurrent neural networks (RNNs) and transformer networks, could be explored to further improve the performance of sentiment analysis models.
