

Outer Bounds on the CEO Problem with Privacy Constraints

Vamoua Yachongka Hideki Yagi Hideki Ochiai

Abstract—We investigate the rate-distortion-leakage region of the Chief Executive Officer (CEO) problem with a passive eavesdropper and privacy constraints, considering a general distortion measure. While an inner bound directly follows from the previous work, an outer bound is newly developed in this paper. To derive this bound, we introduce a new lemma tailored for analyzing privacy constraints. As a specific instance, we demonstrate that the tight bound for discrete and Gaussian sources is obtained when the eavesdropper can only observe the messages under logarithmic loss distortion. We further investigate the rate-distortion-leakage region for a scenario where the eavesdropper possesses the messages and side information under the same distortion, and provide an outer bound for this particular case. The derived outer bound differs from the inner bound by only a minor quantity that appears in the constraints associated with the privacy-leakage rates, and it becomes tight when the distortion is large.

Index Terms—Eavesdropper, logarithmic loss, privacy leakage, rate region, the CEO problem.

I. INTRODUCTION

The Chief Executive Officer (CEO) problem, introduced by Berger et al. in [1], can be viewed as a particular case of multiterminal source coding [2], [3]. As depicted in Fig. 1, multiple encoders observe noisy measurements of a remote source and separately transmit compressed messages to the decoder. The task of the decoder is to reconstruct the original source sequence within a prescribed distortion level, taking into account the independent noises added during the observation process. Practical applications related to this problem encompass a broad range of areas, with a focus on distributed sensor networks [4] and collaborative communications [5].

In the early 1980s, an achievable rate-distortion region of the CEO problem with two encoders was studied in [6]. Later, an alternative expression of the achievable region and some code-design techniques were developed in [7]. The problem was generalized by Berger et al. in [1] for discrete sources. The case of Gaussian sources and quadratic distortion was studied in [8], where the asymptotic trade-off between sum rate and distortion was characterized. This characterization was subsequently refined in [9]. The CEO problem has been broadly investigated in many subsequent papers, but even to date, finding a tight rate-distortion region for a general distortion measure remains to be solved.

H. Yagi is with the Department of Computer and Network Engineering, The University of Electro-Communications, Chofu, Tokyo, 182-8585 Japan.

For some special cases, however, notable progress has been made. The tight rate-distortion region for the quadratic Gaussian CEO problem has been elegantly delineated in [10]–[12]. Numerous extensions of the scalar Gaussian case are found in [13]–[20]. The vector Gaussian source, for which the tight rate-distortion region has not been clarified, is extensively discussed in [21]–[24]. Additionally, some new results have been presented for the non-regular CEO problem in [25], as well as for both regular and non-regular CEO problems incorporating a generalized distortion metric in [26]. Logarithmic loss (log-loss) distortion, which allows the decoder to reproduce the sequence generated by the remote source with a soft decision, emerges as an alternative distortion metric that yields the tight bound for the CEO problem [27]. Based on this fundamental result, a practical coding scheme is proposed in [28], [29] for the binary CEO problem. Expansions to continuous alphabets for complete characterizations of the logarithmic Gaussian CEO problem for scalar and vector Gaussian sources can be found in [30] and [31], respectively.

In physical layer security, privacy conservation of sensitive information sources is important and commonly arises in many real-life applications such as secure-packet transmissions in distributed sensor networks as well as smart-grid systems [32], privacy in database [33], [34], confidential images sharing in satellite communications [35], and key agreement using physical unclonable functions (PUFs) [36], [37]. See also [38]–[41] for discussions of multi-party function computations with privacy. Taking the privacy issues into consideration, multiterminal source coding in the presence of a passive eavesdropper (Eve) has been investigated in [42], [43], where Eve can obtain not only the messages sent over the noise-free link connected among encoders and the decoder but also a correlated sequence of the source, called side information (SI) in this paper. In [43], compared to the conventional setups where the compression-rate and distortion constraints are imposed, the secrecy constraints are newly added in the problem formulation of the CEO problem to evaluate the maximum equivocation rates between the source sequence and the information available at Eve. The authors in [43] derive inner and outer bounds on the rate-distortion-equivocation region under a general distortion measure, and as an example, they also derive an achievable region for the model where the messages and SI are available at Eve, as well as the tight region for a simpler model where Eve does not have access to the correlated sequence under the quadratic distortion.

Nevertheless, with the secrecy constraints, in case one considers log-loss distortion, the tight bound may not be obtained even if the simpler model is taken into consider-

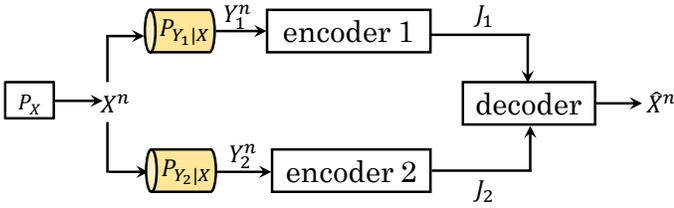

Fig. 1. The CEO problem with two encoders where Y_1^n and Y_2^n denote measurements of source sequence X^n observed through channels $P_{Y_1|X}$ and $P_{Y_2|X}$, respectively. The compressed messages J_1 and J_2 are transmitted to the central decoder over noiseless channels. The decoder utilizes these messages to reconstruct \hat{X}^n , a reproduced sequence of the source X^n .

ation (see Appendix D for a counterexample). In different settings, a privacy-leakage constraint, which evaluates the minimal amount of leakage on the measurement observed at the encoder gained by Eve, is analyzed in multiterminal source coding with an untrusted public helper in [44], where the tight bound under log-loss distortion is attained. Inspired by this result, in this paper, we impose privacy-leakage constraints instead of equivocation constraints in the problem formulation of the CEO problem¹ and aim to characterize the optimal trade-offs among compression rates, privacy-leakage rates, and distortion, referred to as the rate-distortion-leakage region in the sequel, under log-loss distortion. Moreover, we note that the difference between the privacy and secrecy constraints is a conditional entropy. By a simple deduction of the inner bound and outer bounds of the rate-distortion-equivocation region under a general distortion measure derived in [43, Theorems 1 and 2], we can obtain the counterparts on the rate-distortion-leakage region for the CEO problem. However, the resulting expression for the outer bound is somehow simplistic and offers limited insights into the possibility of deriving a tighter bound for the log-loss case. Therefore, in this paper, we are also interested in exploring a novel outer bound for a general distortion measure.

It is worth noting that the recent developments in [45], [46] discuss the utilization of private keys that are confidential from Eve and shared among the encoders and decoder beforehand in order to conceal the privacy of source sequence in multiterminal source coding with decoder-side information. In contrast to these studies, our objective is to determine the minimal achievable privacy-leakage rates without assuming the use of private keys, which is motivated by the fact that the ideal assumption of perfect confidentiality on the private keys from Eve may not be realistic in some practical scenarios [47]. Furthermore, in our system model, the decoder does not have access to a noisy version of the source sequence and is interested in reconstructing the sequence generated by the remote source, rather than the measurements observed at the encoder.

The main contributions of this paper are summarized as follows:

- We derive a novel outer bound on the rate-distortion-leakage region of the CEO problem with Eve under a general distortion measure. Compared to the outer bound

¹We deal only with the CEO problem with two encoders since the m -link ($m \geq 2$) case follows by a straightforward argument [27].

obtained by a simple reduction from [43, Theorem 2], this new bound bears a closer resemblance to the expression of the inner bound. To obtain the novel outer bound, we establish a lemma to bound the privacy-leakage rates and their sum rate explicitly.

- We demonstrate that it is possible to characterize a tight bound for the model without SI at Eve under log-loss distortion for both discrete and Gaussian sources by evaluating the privacy-leakage rates. Moreover, numerical examples are conducted for a case where compression rates are fixed. The obtained results reveal that the distortion is in a saturation state as the privacy-leakage rate becomes large, implying that further improvement on the distortion is not possible. In addition, as the distortion decreases, the compression rates as well as the privacy-leakage rate increase.
- We provide an extended version of the lemma used for analyzing the outer bound under a general distortion measure, and apply this lemma to characterize an outer bound under the log-loss distortion for the model with SI at Eve. The derived bound does not generally match the inner bound, but the difference between these bounds is only a quantity that appears in the constraints of the privacy-leakage rates and their sum rate. Also, when the distortion is large, the inner and outer bounds become tight.

For notation, uppercase X and lowercase x denote a random variable (RV) and its realization, respectively. The probability mass function of RV X is written as $P_X(\cdot)$. The superscript n denotes n -length sequences across time, e.g., $X^n = (X_1, X_2, \dots, X_n)$, where the subscript represents the position of an RV in the string. Denote $X^{n \setminus t} = (X_1, \dots, X_{t-1}, X_{t+1}, \dots, X_n)$ and $X_{\mathcal{A}} = (X_k : k \in \mathcal{A})$ for a set \mathcal{A} . For integers j and k such that (s.t.) $j < k$, $[j : k] = \{j, j+1, \dots, k\}$. The closed interval between real numbers x and y is denoted by $[x, y]$. The set of non-negative real numbers is denoted as \mathbb{R}_+ , $\mathbb{E}[\cdot]$ denotes the expected value of a random variable, and $\log x$ ($x > 0$) is the logarithm of base two.

The rest of this paper is organized as follows: We describe our system model and formulate the achievability definition in Section II. An outer bound on the rate-distortion-leakage region under a general distortion measure is given in Section III. Section IV presents the statement of our main results under log-loss distortion measure, and finally, concluding remarks and future work are given in Section V.

II. SYSTEM MODEL AND PROBLEM FORMULATION

A. System Model

Our system model is described in Fig. 2. Random vectors X^n and \hat{X}^n stand for the source sequence and its reconstructed version, respectively. Assume that the sequence X^n is independently and identically distributed (i.i.d.) generated from the source P_X , and the channel to the first encoder (agent) $f_1(\mathcal{X}, P_{Y_1|X}, \mathcal{Y}_1)$, the channel to the second agent $f_2(\mathcal{X}, P_{Y_2|X}, \mathcal{Y}_2)$, and the channel to Eve ($\mathcal{X}, P_{Z|X}, \mathcal{Z}$) are all

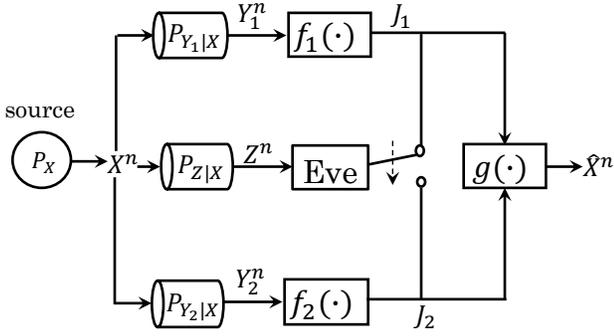

Fig. 2. System model of the CEO problem in the presence of a passive eavesdropper.

discrete and memoryless. The joint distribution of the random vectors X^n, Y_1^n, Y_2^n, Z^n is given as

$$P_{X^n Y_1^n Y_2^n Z^n} = \prod_{t=1}^n P_{Y_{1,t}|X_t} \cdot P_{X_t} \cdot P_{Y_{2,t}|X_t} \cdot P_{Z_t|X_t}. \quad (1)$$

For $k \in \{1, 2\}$, let \mathcal{J}_k be the set of messages generated from the agent f_k . We basically assume that all alphabets $\mathcal{Y}_k, \mathcal{X}$, and \mathcal{Z} are finite, which will be relaxed for the derivation of Gaussian sources in Section IV-A.

The agent f_k generates message $J_k \in \mathcal{J}_k$, which we denote as $J_k = f_k(Y_k^n)$. The message J_k can be regarded as compressed versions of Y_k^n , and both J_1 and J_2 are passed to the decoder g (the CEO or the fusion center) via public noiseless channels, over which the sent information can completely be intercepted by Eve. Upon receiving the messages, the CEO reconstructs a lossy version of the original source sequence as $\hat{X}^n = g(J_1, J_2)$.

The distortion measure between the source and reconstructed sequence is expressed as

$$d^{(n)}(x^n, \hat{x}^n) = \frac{1}{n} \sum_{t=1}^n d(x_t, \hat{x}_t), \quad (2)$$

where $d: \mathcal{X} \times \hat{\mathcal{X}} \rightarrow \mathbb{R}_+$ is a single-letter measure.

Eve observes Z^n and passively eavesdrops on (J_1, J_2) . She uses this information to sniff the source sequence X^n , which is hidden from the public networks. In this paper, our objective is to evaluate the minimum amount of leakage of X^n to Eve.

B. Problem Formulation

The achievability definition of our model is defined as follows:

Definition 1. A tuple of compression rates, privacy-leakage rates, and distortion $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ is said to be achievable if for small enough $\delta > 0$ and large enough n , there exist encoders (f_1, f_2) and decoder g satisfying

$$\log |\mathcal{J}_k| \leq n(R_k + \delta), \quad (\text{storage rate}) \quad (3)$$

$$I(X^n; J_k | Z^n) \leq n(L_k + \delta), \quad (\text{privacy leakage}) \quad (4)$$

$$\mathbb{E}[d^{(n)}(X^n, \hat{X}^n)] \leq D + \delta, \quad (\text{distortion}) \quad (5)$$

for $k \in \{1, 2\}$. \square

Definition 2. \mathcal{R} is defined as the closure of the set of all achievable rate tuples, called the rate-distortion-leakage

region in this paper. Moreover, inner and outer bounds of \mathcal{R} are denoted as \mathcal{R}_{in} and \mathcal{R}_{out} , respectively, where it holds that $\mathcal{R}_{\text{in}} \subseteq \mathcal{R}$ and $\mathcal{R}_{\text{out}} \supseteq \mathcal{R}$. For a special case where the log-loss distortion is used, we deploy $\mathcal{R}_{\text{in}}^L$ and $\mathcal{R}_{\text{out}}^L$ to denote the inner and outer bounds, respectively. \square

The technical meaning of each constraint in Definition 1 can be interpreted as follows: The constraint (3) is imposed to minimize the set of messages to reduce the transmission and hardware cost, (4) evaluates the minimal amount of privacy leakage of the source sequence to Eve², and (5) indicates that the distortion between X^n and \hat{X}^n should not exceed D .

III. INNER AND OUTER BOUNDS FOR GENERAL DISTORTION MEASURE

In this section, we present inner and outer bounds on the rate-distortion-leakage region under a general distortion measure. The inner bound directly stems from the result presented in [43, Theorem 1]. In contrast, the outer bound is newly derived, and its expression shares more similarity with the inner bound compared to the one obtained by a simple deduction from [43, Theorem II].

A. An Inner Bound

The inner bound on the rate-distortion-leakage region is given below, where the time-sharing random variable Q , independent of (X, Y_k, Z) , is used for convexification.

Theorem 1. An inner bound \mathcal{R}_{in} on the rate-distortion-leakage region is characterized as the closure of the set of all rate tuples $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ s.t.

$$R_1 \geq I(Y_1; U_1 | U_2, Q), \quad R_2 \geq I(Y_2; U_2 | U_1, Q), \quad (6)$$

$$R_1 + R_2 \geq I(Y_1, Y_2; U_1, U_2 | Q), \quad (7)$$

$$L_1 \geq I(X; U_1 | U_2, Q) + I(V_1; U_2 | Q) - I(Z; V_1 | Q), \quad (8)$$

$$L_2 \geq I(X; U_2 | U_1, Q) + I(V_2; U_1 | Q) - I(Z; V_2 | Q), \quad (9)$$

$$L_1 + L_2 \geq I(X; U_1, U_2 | Q) + I(V_1; V_2 | Q) - I(Z; V_1 | Q) - I(Z; V_2 | Q), \quad (10)$$

$$R_1 + L_2 \geq I(Y_1, X; U_1, U_2 | Q) - I(Z; V_2 | Q), \quad (11)$$

$$R_2 + L_1 \geq I(X, Y_2; U_1, U_2 | Q) - I(Z; V_1 | Q), \quad (12)$$

$$D \geq \mathbb{E}[d(X, \hat{X}(U_1, U_2, Q))] \quad (13)$$

for all joint distributions $P_{V_1 U_1 Y_1 X Z Y_2 U_2 V_2 Q}$ factorized as

$$P_X P_{Z|X} P_Q \prod_{k=1}^2 P_{Y_k|X} P_{U_k|Y_k Q} P_{V_k|U_k Q} \quad (14)$$

with $|\mathcal{V}_k| \leq |\mathcal{Y}_k| + 8$, $|\mathcal{U}_k| \leq (|\mathcal{Y}_k| + 8)(|\mathcal{Y}_k| + 6)$, $|\mathcal{Q}| \leq 6$, and a reproduction function $\hat{X}: \mathcal{U}_1 \times \mathcal{U}_2 \times \mathcal{Q} \rightarrow \hat{\mathcal{X}}$.

Proof: As the privacy constraint in (4) can be expressed as $H(X^n | Z^n) - H(X^n | J_k, Z^n)$, Theorem 1 is immediately

²In Definition 1, (4) assesses the privacy leakage at each agent separately. The exploration of joint leakage, represented by $I(X^n; J_1, J_2 | Z^n)$ as discussed in [39], [46, Section III], will be a subject of future analysis.

obtained by subtracting the right-hand side of each constraint in [43, Theorem 1] from $H(X|Z)$. For a detailed expansion of the right-hand side of each constraint in [43, Theorem 1] with the Markov chains defined in (14), the readers are referred to [43, Appendix F]. \square

The constraints (6), (7) and (13) in Theorem 1 coincide with the Berger-Tung inner bound [2], [3] when the auxiliary sequences $(V_1^n, U_1^n, U_2^n, V_2^n)$ are reliably estimated at the decoder within a certain distortion level D . Equation (9) expresses the minimal amounts of the privacy-leakage rate at each agent, and (10) is their sum rate. The conditions (11) and (12) reflect trade-offs of the compression and privacy-leakage rates from different agents. This trade-off suggests that in terms of the sum rate, the inner region of the CEO problem with privacy constraints is not only constrained by the sum rate of compression rates and the sum rate of privacy-leakage rates but also a jointly mixed combination of these rates from distinct agents.

B. An Outer Bound

In this subsection, we provide an outer bound on the rate-distortion-leakage region of the CEO problem under a general distortion measure, which is one of the main contributions in this paper. For $k \in \{1, 2\}$, we define the index

$$k' = 3 - k, \quad (15)$$

and an information quantity

$$\xi_k = I(V_k; U_{k'} | Y_k, Y_{k'}, Q). \quad (16)$$

Note that if auxiliary random variables V_1, U_1, U_2, V_2 satisfy the long Markov chain in (14), the quantity ξ_k is just zero.

Theorem 2. *An outer bound \mathcal{R}_{out} on the rate-distortion-leakage region is provided as the closure of the set of all rate tuples $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ s.t.*

$$\begin{aligned} R_1 &\geq I(Y_1; U_1 | U_2, Q), & R_2 &\geq I(Y_2; U_2 | U_1, Q), \\ R_1 + R_2 &\geq I(Y_1, Y_2; U_1, U_2 | Q), \\ L_1 &\geq I(X; V_1 | V_2, Q) + I(V_1; U_2 | Q) - I(Z; V_1 | Q) - \xi_1, \\ L_2 &\geq I(X; V_2 | V_1, Q) + I(V_2; U_1 | Q) - I(Z; V_2 | Q) - \xi_2, \\ L_1 + L_2 &\geq I(X; V_1, V_2 | Q) + I(V_1; V_2 | Q) - I(Z; V_1 | Q) \\ &\quad - I(Z; V_2 | Q) - \min\{\xi_1, \xi_2\}, \\ R_1 + L_2 &\geq I(Y_1; U_1 | U_2, Q) + I(X; V_2 | Q) - I(Z; V_2 | Q), \\ R_2 + L_1 &\geq I(Y_2; U_2 | U_1, Q) + I(X; V_1 | Q) - I(Z; V_1 | Q), \\ D &\geq \mathbb{E}[d(X, \hat{X}(U_1, U_2, Q))], \end{aligned} \quad (17)$$

where random variables $(V_1, U_1, Y_1, X, Z, Y_2, U_2, V_2)$ satisfy the Markov chain $V_k - U_k - Y_k - X - (Y_{k'}, Z)$ for given k and Q . The cardinalities of auxiliary random variables can be limited to $|\mathcal{V}_k| \leq |\mathcal{Y}_k| + 10$ and $|\mathcal{U}_k| \leq (|\mathcal{Y}_k| + 10)(|\mathcal{Y}_k| + 5)$, $|\mathcal{Q}| \leq 6$, and a reproduction function $\hat{X} : \mathcal{U}_1 \times \mathcal{U}_2 \times \mathcal{Q} \rightarrow \mathcal{X}$.

Proof: See Appendix A. \square

IV. LOG-LOSS DISTORTION MEASURE

For log-loss distortion measure, the reconstruction alphabet $\hat{\mathcal{X}}$ is defined as the set of probability distributions on \mathcal{X} . Given

$x_t \in \mathcal{X}$ and $\hat{x}_t \in \hat{\mathcal{X}}$, the symbol-wise distortion in (2) is defined as

$$d(x_t, \hat{x}_t) = \log \left(\frac{1}{\hat{x}_t(x_t)} \right) \quad \text{for } t \in [1 : n], \quad (18)$$

where $\hat{x}_t(\cdot)$ is the t th symbol in the reconstructed sequence \hat{x}^n , and this distribution is evaluated based on the outcome x_t . The readers may refer to [27, Section II] and [28] for more details about its definition and the motivation for using this distortion metric in multiterminal source coding problems.

A. Tight Bounds for the Model Without SI at Eve

The model that we deal with in this section corresponds to a special case of the one shown in Fig. 2 where Z is independent of other random variables. For this model, the auxiliary random variable $V_k, k \in \{1, 2\}$, does not appear in the expression of the rate-distortion-leakage region, and it is shown to be exactly tight.

For discrete sources, the following inner and outer bounds are obtained. We present the expressions of these bounds in detail so as to facilitate the comprehension of a difference on the rate-distortion-leakage region compared to the model with SI at Eve in the upcoming subsection.

Proposition 1. *An inner bound $\mathcal{R}_{\text{in}}^{\text{L}}$ on the rate-distortion-leakage region of the model without SI at Eve under log-loss distortion is given as the closure of the set of all tuples $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ s.t.*

$$\begin{aligned} R_1 &\geq I(Y_1; U_1 | U_2, Q), & R_2 &\geq I(Y_1; U_2 | U_1, Q), \\ R_1 + R_2 &\geq I(Y_1, Y_2; U_1, U_2 | Q) \\ L_1 &\geq I(X; U_1 | U_2, Q), & L_2 &\geq I(X; U_2 | U_1, Q), \\ L_1 + L_2 &\geq I(X; U_1, U_2 | Q), \\ R_1 + L_2 &\geq I(Y_1, X; U_1, U_2 | Q), \\ R_2 + L_1 &\geq I(X, Y_2; U_1, U_2 | Q), \\ D &\geq H(X | U_1, U_2, Q) \end{aligned} \quad (19)$$

for all joint distributions

$$P_{QXY_1Y_2U_1U_2} = P_Q P_X P_{Y_1|X} P_{U_1|Y_1Q} P_{Y_2|X} P_{U_2|Y_2Q} \quad (24)$$

with $|\mathcal{U}_k| \leq |\mathcal{Y}_k| + 3$ and $|\mathcal{Q}| \leq 6$.

Proof: The proof follows by setting V_k and Z as constants and choosing the reproduction function $\hat{X}(U_1, U_2, Q) = P_{X|U_1U_2Q}(x|U_1, U_2, Q)$ for $x \in \mathcal{X}$ in Theorem 1. \square

Proposition 2. *An outer bound $\mathcal{R}_{\text{out}}^{\text{L}}$ is characterized as the closure of the set of all tuples $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ s.t.*

$$\begin{aligned} R_1 &\geq I(Y_1; U_1 | X, Q) + H(X | U_2, Q) - D, \\ R_2 &\geq I(Y_2; U_2 | X, Q) + H(X | U_1, Q) - D, \\ R_1 + R_2 &\geq I(Y_1; U_1 | X, Q) + I(Y_2; U_2 | X, Q) \\ &\quad + H(X) - D, \\ L_1 &\geq H(X | U_2, Q) - D, \\ L_2 &\geq H(X | U_1, Q) - D, \\ L_1 + L_2 &\geq H(X) - D, \\ R_1 + L_2 &\geq I(Y_1; U_1 | X, Q) + H(X) - D, \\ R_2 + L_1 &\geq I(Y_2; U_2 | X, Q) + H(X) - D, \\ D &\geq H(X | U_1, U_2, Q) \end{aligned} \quad (25)$$

$$R_2 \geq I(Y_2; U_2 | X, Q) + H(X | U_1, Q) - D, \quad (26)$$

$$R_1 + R_2 \geq I(Y_1; U_1 | X, Q) + I(Y_2; U_2 | X, Q) + H(X) - D, \quad (27)$$

$$L_1 \geq H(X | U_2, Q) - D, \quad (28)$$

$$L_2 \geq H(X | U_1, Q) - D, \quad (29)$$

$$L_1 + L_2 \geq H(X) - D, \quad (30)$$

$$R_1 + L_2 \geq I(Y_1; U_1 | X, Q) + H(X) - D, \quad (31)$$

$$R_2 + L_1 \geq I(Y_2; U_2 | X, Q) + H(X) - D, \quad (32)$$

$$D \geq H(X | U_1, U_2, Q) \quad (33)$$

for the joint distribution defined in (24) with $|\mathcal{U}_k| \leq |\mathcal{Y}_k| + 3$ and $|Q| \leq 6$.

Proof: See Appendix B. \square

Although the expression of the inner bound in Proposition 1 is different from that of the outer bound in Proposition 2, it can be shown that these regions are equivalent by the same technique used in [27, Proof of Theorem 3]. The readers may also refer to Appendix E for a detailed discussion. Therefore, we have the following theorem.

Theorem 3. *The rate-distortion-leakage region of the CEO problem under log-loss distortion is characterized as*

$$\mathcal{R} = \mathcal{R}_{\text{in}}^L = \mathcal{R}_{\text{out}}^L. \quad (34)$$

\square

Constraints (25)–(27), and (33) in Proposition 2 are the rate-distortion region of the typical CEO problem under log-loss distortion measure [27, Theorem 2].

Next, we derive a tight bound for Gaussian sources and channels. Consider that each symbol of the sources $X \sim \mathcal{N}(0, \sigma_X^2)$, which is a Gaussian distribution with zero mean and variance σ_X^2 , and the channels $P_{Y_1|X}$ and $P_{Y_2|X}$ are respectively modeled as $Y_1 = X + N_1$ and $Y_2 = X + N_2$, where the noises of each channel are $N_1 \sim \mathcal{N}(0, \sigma_{N_1}^2)$ and $N_2 \sim \mathcal{N}(0, \sigma_{N_2}^2)$.

Here, let \mathcal{S} be a subset of the set $\{1, 2\}$, and its complement set is denoted by \mathcal{S}^c . This notation rule is applied to other sets as well.

Theorem 4. *The region \mathcal{R} for Gaussian sources under log-loss distortion measure is characterized by the set of all tuples $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ satisfying*

$$\sum_{k \in \mathcal{K}} R_k + \sum_{k' \in \mathcal{K}^c} L_{k'} \geq \sum_{k \in \mathcal{K}} r_k + \frac{1}{2} \log 2\pi e \left(\frac{1}{\sigma_X^2} + \sum_{j \in \mathcal{S}^c} \frac{1 - 2^{-2r_j}}{\sigma_{N_j}^2} \right)^{-1} - D \quad (35)$$

for all $\mathcal{K} \subseteq \mathcal{S}$ s.t. $\mathcal{K} \cup \mathcal{K}^c = \mathcal{S}$ and all $\mathcal{S} \subseteq \{1, 2\}$ s.t. $\mathcal{S} \cup \mathcal{S}^c = \{1, 2\}$, and some $r_1, r_2 \geq 0$.

Proof: See Appendix C. \square

In case the privacy-leakage rates are not considered, i.e., $L_{k'}$ can be removed from (35), Theorem 4 reduces to the rate-distortion region of the CEO problem under log-loss distortion derived in [30, Theorem 5].

Remark 1. *It should be noted that the rate-distortion-leakage region of the quadratic Gaussian CEO problem where the symbol-wise distortion in (2) is measured by*

$$d(x_t, \hat{x}_t) = (x_t - \hat{x}_t)^2 \quad \text{for } t \in [1 : n], \quad (36)$$

is also tight for this simpler model. The obtained region is given by a similar form of Theorem 4 by replacing the constraint (35) with the following inequality

$$\sum_{k \in \mathcal{K}} R_k + \sum_{k' \in \mathcal{K}^c} L_{k'} \geq \sum_{k \in \mathcal{K}} r_k + \frac{1}{2} \log \left(\frac{1}{D} \left(\frac{1}{\sigma_X^2} + \sum_{j \in \mathcal{S}^c} \frac{1 - 2^{-2r_j}}{\sigma_{N_j}^2} \right)^{-1} \right) \quad (37)$$

for all $\mathcal{K} \subseteq \mathcal{S}$ s.t. $\mathcal{K} \cup \mathcal{K}^c = \mathcal{S}$ and all $\mathcal{S} \subseteq \{1, 2\}$ s.t. $\mathcal{S} \cup \mathcal{S}^c = \{1, 2\}$, and some $r_1, r_2 \geq 0$. See [43, Appendix F] for a similar proof.

This result matches the rate-distortion region of the quadratic Gaussian CEO problem derived in [10]–[12] as a special case where the privacy-leakage rates are not considered.

B. Numerical Examples

In this section, we examine the relationship between privacy-key rate L_1 and minimum distortion D (min D) for a practical situation where both the compression rates R_1 and R_2 are fixed. Additionally, the constraint of privacy-leakage rate L_2 is relaxed in the calculations. The detailed numerical results are shown in Figure 3, where Figures 3(a) and 3(b) correspond to the curves of the Gaussian CEO problem under log-loss distortion (Theorem 4) and quadratic distortion (Remark 1), respectively. Relevant parameters are summarized in Table I.

TABLE I
LIST OF PARAMETERS AND CORRESPONDING CURVES IN FIG. 3.

Variances			Rates		Results
σ_X^2	$\sigma_{N_1}^2$	$\sigma_{N_2}^2$	R_1	R_2	
2	1	1	0.5	0.5	blue curves marked with circles
2	1	1	1.0	0.5	blue curves marked with triangles
5	1	1	0.5	0.5	red curves marked with circles
5	1	1	1.0	0.5	red curves marked with triangles

From the behaviors of each graph, one can see that when the privacy-leakage rate L_1 becomes large, the minimum distortion is in a saturation state, and this appearance is justified below. For brevity, we use the quadratic Gaussian case to explain this phenomenon. After performing some algebras, alternative forms for the constraints on L_1 are expressed as follows:

$$D \geq 2^{-2L_1} \left(\frac{1}{\sigma_X^2} + \frac{1 - 2^{-2r_2}}{\sigma_{N_2}^2} \right)^{-1}, \quad D \geq 2^{-2(L_1 + R_2 - r_2)} \sigma_X^2 \quad (38)$$

for some $r_1, r_2 \geq 0$.

Since both R_1 and R_2 are fixed at 0.5, from the constraints in (37), it is clear that the ranges of r_1 and r_2 are limited to $[0, 0.5]$. When L_1 is large, i.e., 2^{-2L_1} converges to zero exponentially, the conditions in (38) become redundant. The minimum value of distortion D subject to other constraints in (37) when r_1 and r_2 vary over $[0, 0.5] \times [0, 0.5]$ remains unchanged, and therefore the saturation occurs. The same observation follows in the case of log-loss distortion measure (cf. Fig. 3(a)). The relationship of linearity of L_1 with minimum D in the low rate regime of L_1 is obvious from the constraints in Theorem 4. Moreover, from the behaviors of graphs in Figure 3, it is clear that for the rate pair $(R_1, R_2) = (1.0, 0.5)$, a lower value in regard to the minimum D is achievable compared to the case of $(R_1, R_2) = (0.5, 0.5)$, which implies that the smaller the distortion, the larger the compression and privacy-leakage rates.

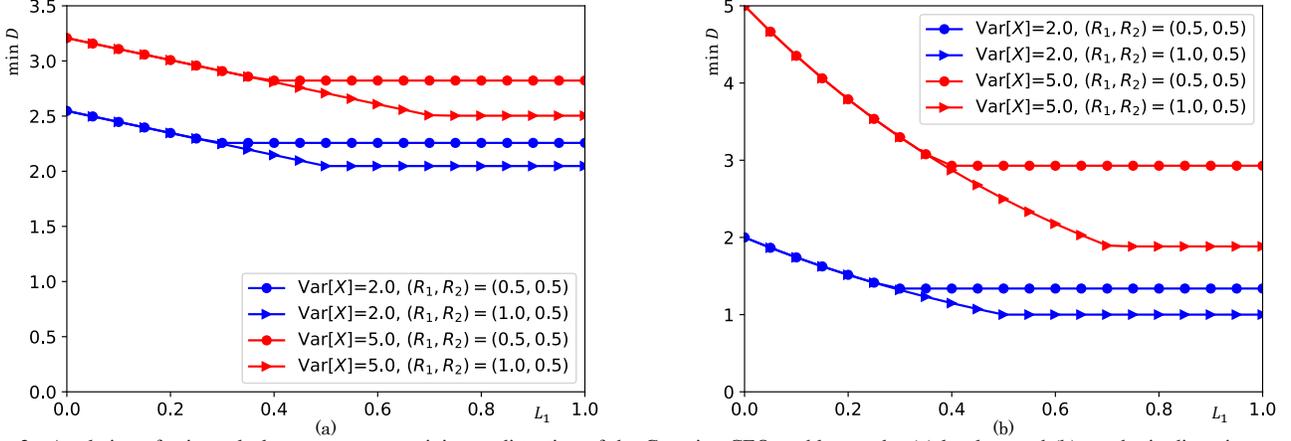

Fig. 3. A relation of privacy-leakage rate versus minimum distortion of the Gaussian CEO problem under (a) log-loss and (b) quadratic distortion measures.

C. Inner and Outer Bounds for the Model With SI at Eve

In the previous subsection, we have seen that for the model without SI at Eve, the exact rate region under log-loss distortion is derivable for both discrete and Gaussian sources. However, this is not the case for the model where SI is available at Eve. In the following, we provide inner and outer bounds for the model with SI at Eve. The inner bound is given below.

Proposition 3. An inner bound $\mathcal{R}_{\text{in}}^{\text{L}}$ on the rate-distortion-leakage region under log-loss distortion is given by all constraints in \mathcal{R}_{in} defined in Theorem 1 with replacing the distortion constraint (13) by

$$D \geq H(X|U_1, U_2, Q), \quad (39)$$

where auxiliary random variables V_k, U_k for $k \in \{1, 2\}$ satisfy the joint distribution (14) with their cardinalities bounded as $|\mathcal{V}_k| \leq |\mathcal{Y}_k| + 8$, $|\mathcal{U}_k| \leq (|\mathcal{Y}_k| + 8)(|\mathcal{Y}_k| + 6)$, and $|\mathcal{Q}| \leq 6$.

Proof: The proof is straightforward from Theorem 1 by considering $\hat{X}(U_1, U_2, Q) = P_{X|U_1 U_2 Q}(x|U_1, U_2, Q)$ for $x \in \mathcal{X}$. \square

Upon comparing Propositions 1 and 3, one can observe that the difference between these regions appears in the constraints related to the privacy-leakage rates. For example, the difference between the privacy-leakage rate L_1 of the first agent for the model with and without SI at Eve is $I(V_1; U_2|Q) - I(Z; V_1|Q)$. This quantity indeed serves as an upper bound on the term $-I(Z^n; J_1)$ when evaluating the privacy-leakage rate in the achievability part, as it can be expanded as $I(X^n; J_k|Z^n) = I(X^n; J_k) - I(Z^n; J_k)$.

Hereafter, we exhibit an outer bound on the rate-distortion-leakage region in the context of log-loss distortion. A genuine challenge for deriving the outer bound lies in providing the optimal lower bound for the term $-I(Z^n; J_k)$, that is, it should be lower bounded by $I(V_1; U_2|Q) - I(Z; V_1|Q)$ when the blocklength is sufficiently large. In the proof, while the optimal lower bound for this term has not been achieved, a lower bound that is close to the desired upper one is derived.

To present an outer bound of the rate-distortion-leakage region under log-loss distortion, let us define $\xi' = I(V_1; V_2|Q)$.

Proposition 4. An outer bound $\mathcal{R}_{\text{out}}^{\text{L}}$ is given as the closure of the set of all rate tuples $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ s.t.

$$\begin{aligned} R_1 &\geq I(Y_1; U_1|X, Q) + H(X|U_2, Q) - D, \\ R_2 &\geq I(Y_2; U_2|X, Q) + H(X|U_1, Q) - D, \\ R_1 + R_2 &\geq I(Y_1; U_1|X, Q) + I(Y_2; U_2|X, Q) + H(X) - D, \\ L_1 &\geq H(X|U_2, Q) - D + I(V_1; U_2|Q) \\ &\quad - I(Z; V_1|Q) - \xi', \\ L_2 &\geq H(X|U_1, Q) - D + I(V_2; U_1|Q) \\ &\quad - I(Z; V_2|Q) - \xi', \\ L_1 + L_2 &\geq H(X) - D + I(V_1; V_2|Q) - I(Z; V_1|Q) \\ &\quad - I(Z; V_2|Q) - \xi', \\ R_1 + L_2 &\geq I(Y_1; U_1|X, Q) + H(X) - D - I(Z; V_2|Q), \\ R_2 + L_1 &\geq I(Y_2; U_2|X, Q) + H(X) - D - I(Z; V_1|Q), \\ D &\geq H(X|U_1, U_2, Q), \end{aligned} \quad (40)$$

where auxiliary random variables V_k, U_k for $k \in \{1, 2\}$ satisfy the joint distribution (14) with $|\mathcal{V}_k| \leq |\mathcal{Y}_k| + 9$, $|\mathcal{U}_k| \leq (|\mathcal{Y}_k| + 9)(|\mathcal{Y}_k| + 4)$, and $|\mathcal{Q}| \leq 6$.

Proof: See Appendix C. \square

As a final remark, the established outer bound in Proposition 4 is not yet tight, which can be confirmed when examining the scenario where the distortion is optimal, namely, when $D = H(X|U_1, U_2, Q)$. For this case, it is evident that $\mathcal{R}_{\text{in}}^{\text{L}} \subseteq \mathcal{R}_{\text{out}}^{\text{L}}$ due to the inclusion of ξ' in the constraints of the privacy-leakage rates and their sum rate. Consequently, the characterization of the tight bound for the CEO problem, in which Eve possesses SI under log-loss distortion, remains an open question. Nevertheless, only under the specific situation where the distortion $D \geq I(Y_1; U_1|X, Q) + I(Y_2; U_2|X, Q) + H(X)$, the inner and outer bounds coincide. This follows because any point $(0, 0, 0, 0, D)$ with $D \geq I(Y_1; U_1|X, Q) + I(Y_2; U_2|X, Q) + H(X)$ in Proposition 4 is dominated by the point $(0, 0, 0, 0, H(X))$, achieved by setting all auxiliary random variables (V_1, U_1, U_2, V_2) as constants in Proposition 3.

V. CONCLUSIONS

In this work, we have investigated an outer bound on the rate-distortion-leakage region for the CEO problem in the presence of Eve. As a special case where the log-loss distortion measure is used at the CEO, we have shown that the inner and outer bounds of the model without SI at Eve are exactly tight. Also, we have derived an outer bound for the model where SI is available at Eve and shown that the outer bound is close to the inner bound but not yet tight in general. As a direction for future research, the characterization of the tight bound remains open for both quadratic and log-loss distortion in the model with SI at Eve. Investigating and establishing the tight bound for this model is of significant interest.

APPENDIX A PROOF OF THEOREM 2

Assume that a rate tuple $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ is achievable with respect to Definition 1, implying that there exists at least one pair of encoder and decoder that satisfies all the conditions in Definition 1. As in [43], define $V_{k,t} = (J_k, X^{t-1})$ and $U_{k,t} = (J_k, Y_k^{t-1}, Y_{k'}^{t-1}, X^{t-1})$ for $k \in \{1, 2\}$ and $t \in [1 : n]$, where the definition of k' follows (15). These settings guarantee the Markov chains

$$V_{k,t} - U_{k,t} - Y_{k,t} - X^t - (Y_{k',t}, Z_t). \quad (41)$$

Prior to the detailed proof, we introduce an important lemma that enables us to find the single-letter expression for the outer bound on the rate-distortion-leakage region, which serves as a key contribution of this proof.

Lemma 1. Define $\xi_{k,t} = I(V_{k,t}; U_{k',t} | Y_{k,t}, Y_{k',t})$. Then, we have that

$$I(J_k; J_{k'}) - I(Z^n; J_k) \geq \sum_{t=1}^n \{I(V_{k,t}; U_{k',t}) - I(Z_t; V_{k,t}) - \xi_{k,t}\}. \quad (42)$$

Proof: Observe that

$$\begin{aligned} I(J_k; J_{k'}) - I(Z^n; J_k) &= H(J_k | Z^n) - H(J_k | J_{k'}) \\ &= H(Y_k^n, J_k | Z^n) - H(Y_k^n | J_k, Z^n) - H(Y_k^n, Y_{k'}^n, J_k | J_{k'}) \\ &\quad + H(Y_k^n, Y_{k'}^n | J_k, J_{k'}) \\ &= H(Y_k^n | Z^n) - H(Y_k^n | J_k, Z^n) - H(Y_k^n, Y_{k'}^n | J_{k'}) \\ &\quad + H(Y_k^n, Y_{k'}^n | J_k, J_{k'}) \end{aligned} \quad (43)$$

$$\begin{aligned} &\stackrel{(a)}{=} \sum_{t=1}^n \{H(Y_{k,t} | Z_t) - H(Y_{k,t} | J_k, X^{t-1}, Y_k^{t-1}, Z^n) \\ &\quad - H(Y_{k,t}, Y_{k',t} | J_{k'}, X^{t-1}, Y_k^{t-1}, Y_{k'}^{t-1}) \\ &\quad + H(Y_{k,t}, Y_{k',t} | J_k, J_{k'}, X^{t-1}, Y_k^{t-1}, Y_{k'}^{t-1})\} \\ &\stackrel{(b)}{\geq} \sum_{t=1}^n \{H(Y_{k,t} | Z_t) - H(Y_{k,t} | J_k, X^{t-1}, Z_t) \\ &\quad - H(Y_{k,t}, Y_{k',t} | U_{k',t}) + H(Y_{k,t}, Y_{k',t} | V_{k,t}, U_{k',t})\} \end{aligned} \quad (44)$$

$$\begin{aligned} &= \sum_{t=1}^n \{H(Y_{k,t} | Z_t) - H(Y_{k,t} | V_{k,t}, Z_t) - H(Y_{k,t}, Y_{k',t} | U_{k',t}) \\ &\quad + H(Y_{k,t}, Y_{k',t} | V_{k,t}, U_{k',t})\} \\ &= \sum_{t=1}^n \{I(Y_{k,t}; V_{k,t} | Z_t) - H(Y_{k,t} | U_{k',t}) + H(Y_{k,t} | V_{k,t}, U_{k',t}) \\ &\quad - H(Y_{k',t} | Y_{k,t}, U_{k',t}) + H(Y_{k',t} | Y_{k,t}, V_{k,t}, U_{k',t})\} \\ &= \sum_{t=1}^n \{I(Y_{k,t}; V_{k,t} | Z_t) - I(V_{k,t}; Y_{k,t} | U_{k',t}) \\ &\quad - I(V_{k,t}; Y_{k',t} | Y_{k,t}, U_{k',t})\} \\ &\stackrel{(c)}{=} \sum_{t=1}^n \{H(V_{k,t} | Z_t) - H(V_{k,t} | Y_{k,t}) - H(V_{k,t} | U_{k',t}) \\ &\quad + H(V_{k,t} | Y_{k,t}, U_{k',t}) - I(V_{k,t}; Y_{k',t} | Y_{k,t}, U_{k',t})\} \\ &= \sum_{t=1}^n \{H(V_{k,t} | Z_t) - H(V_{k,t} | U_{k',t}) - I(V_{k,t}; U_{k',t} | Y_{k,t}) \\ &\quad - I(V_{k,t}; Y_{k',t} | Y_{k,t}, U_{k',t})\} \\ &= \sum_{t=1}^n \{I(V_{k,t}; U_{k',t}) - I(Z_t; V_{k,t}) - I(V_{k,t}; Y_{k',t}, U_{k',t} | Y_{k,t})\} \\ &\stackrel{(d)}{=} \sum_{t=1}^n \{I(V_{k,t}; U_{k',t}) - I(Z_t; V_{k,t}) - \xi_{k,t}\}, \end{aligned} \quad (45)$$

where (a) is due to the Markov chains $Y_{k,t} - (J_k, Y_k^{t-1}, Z^n) - X^{t-1}$ and $(Y_{k,t}, Y_{k',t}) - (J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) - X^{t-1}$, (b) follows as conditioning reduces entropy, and (c) and (d) hold by the Markov chains $V_{k,t} - Y_{k,t} - Z_t$ and $V_{k,t} - Y_{k,t} - Y_{k',t}$, respectively. \square

For the compression-rate and distortion constraints, the discussions are omitted as they follow the steps demonstrated in [43, Appendix C]. That is, for any $\mathcal{S} \subseteq \{1, 2\}$, it holds that

$$n \left(\sum_{k \in \mathcal{S}} R_k + |\mathcal{S}| \delta \right) \geq \sum_{t=1}^n I(Y_{\mathcal{S},t}; U_{\mathcal{S},t} | U_{\mathcal{S}^c,t}), \quad (46)$$

$$n(D + \delta) \geq \sum_{t=1}^n \mathbb{E}[d(X_t, \hat{X}_t(U_{k,t}, U_{k',t}))]. \quad (47)$$

The analyses of the privacy-leakage rates, their sum rate, and the mixed sum rate are verified as follows:

i) *Analysis of the Privacy-Leakage Rate:* From (4), we have

$$\begin{aligned} n(L_k + \delta) &\geq I(X^n; J_k | Z^n) \stackrel{(a)}{=} I(X^n; J_k) - I(Z^n; J_k) \\ &\stackrel{(b)}{=} I(X^n; J_k | J_{k'}) + I(J_{k'}; J_k) - I(Z^n; J_k) \\ &= \sum_{t=1}^n I(X_t; J_k | J_{k'}, X^{t-1}) + I(J_{k'}; J_k) - I(Z^n; J_k) \\ &= \sum_{t=1}^n I(X_t; J_k, X^{t-1} | J_{k'}, X^{t-1}) + I(J_{k'}; J_k) - I(Z^n; J_k) \\ &\stackrel{(c)}{\geq} \sum_{t=1}^n \{I(X_t; V_{k,t} | V_{k',t}) + I(V_{k,t}; U_{k',t}) - I(Z_t; V_{k,t}) \\ &\quad - \xi_{k,t}\}, \end{aligned} \quad (49)$$

where (a) and (b) are due to the Markov chains $J_k - X^n - Z^n$ and $J_k - X^n - J_{k'}$, respectively, and (c) follows since Lemma 1 applies.

ii) *Analysis of the Sum Rate:* Again from (4), on one hand, observe that

$$\begin{aligned}
n(L_1 + L_2 + 2\delta) &\geq I(X^n; J_1 | Z^n) + I(X^n; J_2 | Z^n) \\
&= I(X^n; J_1) + I(X^n; J_2) - I(Z^n; J_1) - I(Z^n; J_2) \quad (50) \\
&= I(X^n; J_1) + I(X^n; J_2 | J_1) + I(J_1; J_2) - I(Z^n; J_1) \\
&\quad - I(Z^n; J_2) \\
&\stackrel{(a)}{\geq} \sum_{t=1}^n \{I(X_t; J_1, J_2, X^{t-1}) - I(Z_t; J_2, X^{t-1}, Z^{t-1})\} \\
&\quad + I(J_1; J_2) - I(Z^n; J_1) \\
&\stackrel{(b)}{=} \sum_{t=1}^n \{I(X_t; V_{1,t}, V_{2,t}) - I(Z_t; V_{2,t})\} \\
&\quad + I(J_1; J_2) - I(Z^n; J_1) \\
&\stackrel{(c)}{\geq} \sum_{t=1}^n \{I(X_t; V_{1,t}, V_{2,t}) + I(V_{1,t}; V_{2,t}) - I(Z_t; V_{1,t}) \\
&\quad - I(Z_t; V_{2,t}) - \xi_{1,t}\}, \quad (51)
\end{aligned}$$

where (a) holds since each symbol of (X^n, Z^n) is i.i.d. generated and thus $\sum_{t=1}^n I(X_t; X^{t-1}) = \sum_{t=1}^n I(Z_t; Z^{t-1}) = 0$, (b) is due to the Markov chain $Z_t - (J_2, X^{t-1}) - Z^{t-1}$, and (c) is due to Lemma 1.

On the other hand, in (50), we can also rearrange the equation as $I(X^n; J_2) + I(X^n; J_1 | J_2) - I(Z^n; J_1) + I(J_2; J_1) - I(Z^n; J_2)$. Tracing the steps from (50) to (51), we also obtain

$$\begin{aligned}
n(L_1 + L_2 + 2\delta) &\geq \sum_{t=1}^n \{I(X_t; V_{1,t}, V_{2,t}) + I(V_{1,t}; V_{2,t}) \\
&\quad - I(Z_t; V_{1,t}) - I(Z_t; V_{2,t}) - \xi_{2,t}\}. \quad (52)
\end{aligned}$$

As a result, it follows that

$$\begin{aligned}
n(L_1 + L_2 + 2\delta) &\geq \sum_{t=1}^n \{I(X_t; V_{1,t}, V_{2,t}) + I(V_{1,t}; V_{2,t}) \\
&\quad - I(Z_t; V_{1,t}) - I(Z_t; V_{2,t}) - \min\{\xi_{1,t}, \xi_{2,t}\}\}. \quad (53)
\end{aligned}$$

iii) *Analysis of the Mixed Sum Rate:* From (3) and (4),

$$\begin{aligned}
n(R_{k'} + L_k + 2\delta) &\geq \log |\mathcal{J}_{k'}| + I(X^n; J_k | Z^n) \\
&\geq H(J_{k'}) + I(X^n; J_k) - I(Z^n; J_k) \quad (54) \\
&= H(J_{k'} | J_k) + I(X^n; J_k) + I(J_k; J_{k'}) - I(Z^n; J_k) \\
&\geq H(J_{k'} | J_k) + I(X^n; J_k) - I(Z^n; J_k) \\
&\stackrel{(a)}{=} H(J_{k'} | J_k) + \sum_{t=1}^n \{I(X_t; J_k, X^{t-1}) - I(Z_t; J_k, Z^{t-1})\} \\
&\geq H(J_{k'} | J_k) + \sum_{t=1}^n \{I(X_t; J_k, X^{t-1}) \\
&\quad - I(Z_t; J_k, X^{t-1}, Z^{t-1})\} \\
&\stackrel{(b)}{=} \sum_{t=1}^n \{I(Y_{k',t}; U_{k',t} | U_{k,t}) + I(X_t; V_{k,t}) - I(Z_t; V_{k,t})\}, \quad (55)
\end{aligned}$$

where (a) follows from the i.i.d. property of (X^n, Z^n) and (b) is due to the Markov chain $Z_t - (J_k, X^{t-1}) - Z^{t-1}$.

The proof is wrapped up with the standard single-letterization argument by considering a time-sharing random

variable $Q \sim \text{Unif}[1 : n]$ and denoting $X = X_Q$, $Z = Z_Q$, $Y_k = Y_{k,Q}$, $Y_{k'} = Y_{k',Q}$, $U_k = V_{k,Q}$, and $V_k = V_{k,Q}$ for given Q , so that the Markov chain $V_k - U_k - Y_k - X - (Y_{k'}, Z)$ holds.

Moreover, using the support lemma [48, Appendix C], one can show that it suffices to limit $|\mathcal{Y}_k| \leq |\mathcal{Y}_k| + 10$ and $|\mathcal{U}_k| \leq (|\mathcal{Y}_k| + 10)(|\mathcal{Y}_k| + 5)$ for preserving \mathcal{R}_{out} . Furthermore, $|\mathcal{Q}| \leq 6$ follows from the Fenchel-Eggleston-Carathéodory theorem [48, Appendix A]. Finally, by letting $n \rightarrow \infty$ and $\delta \downarrow 0$, the converse proof completes. \square

APPENDIX B

PROOF OF PROPOSITION 2 AND THEOREM 4

A. Proof of Proposition 2

For the converse part, again assume that a rate tuple $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ is achievable with respect to Definition 1.

For $k \in \{1, 2\}$ and $t \in [1 : n]$, as in [27], we define $U_{k,t} = (J_k, Y_k^{t-1})$ and $Q_t = X^{n,t}$. Note that conditioned on Q_t , the random variables $(V_{k,t}, U_{k,t}, Y_{k,t}, X_t, Z_t)$ satisfy the long Markov chain defined by (24).

The next lemma is useful for simplifying equation developments during the analysis. For a set $\mathcal{K} \subseteq \{1, 2\}$, the notation $J_{\mathcal{K}} = 0$ for $\mathcal{K} = \emptyset$, $J_{\mathcal{K}} = J_1$ or J_2 for $\mathcal{K} = \{1\}$ or $\{2\}$, respectively, and $J_{\mathcal{K}} = (J_1, J_2)$ for $\mathcal{K} = \{1, 2\}$.

Lemma 2. *It holds that for all $\mathcal{K} \subseteq \{1, 2\}$,*

$$H(J_{\mathcal{K}} | X^n) = \sum_{k \in \mathcal{K}} \left\{ \sum_{t=1}^n I(Y_{k,t}; U_{k,t} | X_t, Q_t) \right\}. \quad (56)$$

Proof: The equation can be developed as

$$\begin{aligned}
H(J_{\mathcal{K}} | X^n) &= H(Y_{\mathcal{K}}^n, J_{\mathcal{K}} | X^n) - H(Y_{\mathcal{K}}^n | J_{\mathcal{K}}, X^n) \\
&\stackrel{(a)}{=} H(Y_{\mathcal{K}}^n | X^n) - H(Y_{\mathcal{K}}^n | J_{\mathcal{K}}, X^n) \\
&= \sum_{t=1}^n \left\{ H(Y_{\mathcal{K},t} | X^n) - H(Y_{\mathcal{K},t} | J_{\mathcal{K}}, Y_{\mathcal{K}}^{t-1}, X^n) \right\} \\
&= \sum_{t=1}^n \left\{ H(Y_{\mathcal{K},t} | X_t, Q_t) - H(Y_{\mathcal{K},t} | U_{\mathcal{K},t}, X_t, Q_t) \right\} \\
&\stackrel{(b)}{=} \sum_{t=1}^n \left\{ \sum_{k \in \mathcal{K}} I(Y_{k,t}; U_{k,t} | X_t, Q_t) \right\}, \quad (57)
\end{aligned}$$

where (a) follows because $J_{\mathcal{K}}$ is a function of $Y_{\mathcal{K}}^n$, and (b) is due to the Markov chain $Y_{k,t} - (X_t, U_{k,t}) - (Y_{k',t}, U_{k',t})$ for $k \in \{1, 2\}$. \square

Now we start analyzing each constraint. For the compression rates and distortion constraint, it was shown in [27] that for any $\mathcal{S} \subseteq \{1, 2\}$,

$$\begin{aligned}
n \left(\sum_{k \in \mathcal{S}} R_k + 2\delta \right) &\geq H(J_{\mathcal{S}}) \geq \sum_{t=1}^n \left\{ H(X_t | U_{\mathcal{S}^c,t}, Q_t) \right\} \\
&\quad + \sum_{k \in \mathcal{S}} \left\{ \sum_{t=1}^n I(Y_{k,t}; U_{k,t} | X_t, Q_t) \right\} - n(D + \delta), \quad (58)
\end{aligned}$$

$$n(D + \delta) \geq \sum_{t=1}^n H(X_t | U_{1,t}, U_{2,t}, Q_t). \quad (59)$$

Note that for a set $\mathcal{K} \subseteq \mathcal{S}$ with $\mathcal{K} \cup \mathcal{K}^c = \mathcal{S}$, the summation $\sum_{k \in \mathcal{S}} \{ \sum_{t=1}^n I(Y_{k,t}; U_{k,t} | X_t, Q_t) \}$ on the right-hand side of (58) can be rewritten as a sum of the following terms

$$\sum_{k \in \mathcal{K}} \left\{ \sum_{t=1}^n I(Y_{k,t}; U_{k,t} | X_t, Q_t) \right\} + \sum_{k' \in \mathcal{K}^c} \left\{ \sum_{t=1}^n I(Y_{k',t}; U_{k',t} | X_t, Q_t) \right\}. \quad (60)$$

In the rest of the proof, we verify the constraints of privacy-leakage rates, their sum rate, and the mixed sum rate between privacy-leakage and compression rates. From (3) and (4) with $Z = \emptyset$, for all $\mathcal{K} \subseteq \mathcal{S} \subseteq \{1, 2\}$, we have that

$$\begin{aligned} n \left(\sum_{k \in \mathcal{K}} R_k + \sum_{k' \in \mathcal{K}^c} L_{k'} + 2\delta \right) &\geq \log |\mathcal{J}_{\mathcal{K}}| + \sum_{k' \in \mathcal{K}^c} I(X^n; J_{k'}) \\ &\geq H(J_{\mathcal{K}}) + H(J_{\mathcal{K}^c}) - \sum_{k' \in \mathcal{K}^c} H(J_{k'} | X^n) \\ &\geq H(J_{\mathcal{S}}) - \sum_{k' \in \mathcal{K}^c} H(J_{k'} | X^n) \\ &\stackrel{(a)}{\geq} \sum_{t=1}^n \left\{ H(X_t | U_{\mathcal{S}^c, t}, Q_t) + \sum_{k \in \mathcal{S}} I(Y_{k,t}; U_{k,t} | X_t, Q_t) \right. \\ &\quad \left. - \sum_{k' \in \mathcal{K}^c} I(Y_{k',t}; U_{k',t} | X_t, Q_t) \right\} - n(D + \delta) \\ &\stackrel{(b)}{=} \sum_{t=1}^n \left\{ \sum_{k \in \mathcal{K}} I(Y_{k,t}; U_{k,t} | X_t, Q_t) + H(X_t | U_{\mathcal{S}^c, t}, Q_t) \right\} \\ &\quad - n(D + \delta), \end{aligned} \quad (61)$$

where (a) is due to (56) and (58) and (b) holds since (60) applies. In (61), the constraint on L_k is derived when taking $\mathcal{S} = \{k\}$ and $\mathcal{K} = \emptyset$. The constraint on $L_1 + L_2$ follows from specifying $\mathcal{S} = \{1, 2\}$ and $\mathcal{K} = \emptyset$. In a similar manner, by setting $\mathcal{S} = \{k, k'\}$ and $\mathcal{K} = \{k\}$, we have the constraint on $R_k + L_{k'}$.

By the standard argument for single letterization with defining $X = X_T$, $Z = Z_T$, $Y_k = Y_{k,T}$, $U_k = U_{k,T}$, $V_k = V_{k,T}$, and $Q = (T, Q_T)$ for $T \sim \text{Unif}[1 : n]$, and letting $n \rightarrow \infty$ and $\delta \downarrow 0$, any achievable tuple (R_1, R_2, K_1, K_2, D) of the CEO problem with physical identifiers is contained in \mathcal{R}_{out} .

Moreover, using the Fenchel-Eggleston-Carathéodory theorem [48, Appendix A], one can limit $|\mathcal{Q}| \leq 6$, and by the support lemma [48, Appendix C], we can bound the cardinality on U_k as $|\mathcal{U}_k| \leq |\mathcal{Y}_k| + 3$. \square

B. Proof of Theorem 4

For achievability proof, consider that for $k \in \{1, 2\}$, $U_k = Y_k + \Theta_k$, where $\Theta_k \in \mathcal{N}(0, \sigma_{\Theta_k}^2)$. The rest of the achievability proof follows standard techniques, and thus we omit the details. We refer the readers to [43, Appendix F] for a similar proof.

For the converse part, note that the expression of single-letter characterization in (33) also holds for Gaussian sources. Therefore, we will use the expression to derive the closed-

form expression for the Gaussian case. Similar to the technique developed in [49], [50], for $k \in \{1, 2\}$, let us fix β_k such that

$$\begin{aligned} h(X | U_{\mathcal{S}^c}, Q) &= \frac{1}{2} \log 2\pi e \left(\frac{1}{\sigma_X^2} + \sum_{k \in \mathcal{S}^c} \frac{1}{\sigma_{N_k}^2 + \beta_k} \right)^{-1} \\ &= \frac{1}{2} \log 2\pi e \left(\frac{1}{\sigma_X^2} + \sum_{k \in \mathcal{S}^c} \frac{1 - 2^{-2r_k}}{\sigma_{N_k}^2} \right)^{-1}, \end{aligned} \quad (62)$$

where $r_k = \frac{1}{2} \log \left(\frac{\sigma_{N_k}^2 + \beta_k}{\beta_k} \right)$ for $\beta_k > 0$. Note that $r_k \geq 0$ for any $\beta_k > 0$. When the set \mathcal{S}^c is singleton, (62) reduces to

$$\begin{aligned} h(X | U_k, Q) &= \frac{1}{2} \log 2\pi e \left(\frac{1}{\sigma_X^2} + \frac{1}{\sigma_{N_k}^2 + \beta_k} \right)^{-1} \\ &= \frac{1}{2} \log 2\pi e \left(\frac{\sigma_X^2 (\sigma_{N_k}^2 + \beta_k)}{\sigma_X^2 + \sigma_{N_k}^2 + \beta_k} \right) \end{aligned} \quad (63)$$

for $k \in \{1, 2\}$. It is not so difficult to verify that there exists r_k such that (63) holds. The setting in (63) stems from the fact that the term inside the parenthesis is a continuous and monotonically decreasing function with respect to r_k , and when the auxiliary RV U_k varies, there always exists a r_k satisfying this condition since one can see that $\frac{1}{2} \log 2\pi e \left(\frac{\sigma_X^2 \sigma_{N_k}^2}{\sigma_X^2 + \sigma_{N_k}^2} \right) = h(X | Y_k) \leq h(X | U_k, Q) \leq h(X) = \frac{1}{2} \log 2\pi e \sigma_X^2$ holds. By taking $r_k = +\infty$ ($\beta_k \rightarrow 0$) and $r_k = 0$ ($\beta_k \rightarrow \infty$), we achieve the lower and upper bound this relation. By a similar analogy, we can check that (62) holds for any set of \mathcal{S}^c .

To further bound the right-hand side in (33) for Gaussian sources, we need to lower bound the terms $I(Y_k; U_k | X, Q)$ and $h(X | U_{\mathcal{S}^c}, Q)$. Now observe that the term $I(Y_k; U_k | X, Q) = I(Y_k; U_k | Q) - I(X; U_k | X, Q) = h(Y_k) - h(Y_k | U_k, Q) - h(X) + h(X | U_k, Q)$. Since $h(Y_k)$ and $h(X)$ are constant, and $h(X | U_k, Q)$ is obtained from (63), the remaining tasks are to derive the optimal upper bound on $H(Y_k | U_k, Q)$. Following the technique used in [51], the converted channel from Y_k to X is given as

$$X = \frac{\sigma_X^2}{\sigma_X^2 + \sigma_{N_k}^2} Y_k + N'_k, \quad N'_k \sim \mathcal{N}\left(0, \frac{\sigma_X^2 \sigma_{N_k}^2}{\sigma_X^2 + \sigma_{N_k}^2}\right). \quad (64)$$

Applying the conditional entropy power inequality [52] to (64) yields

$$\begin{aligned} 2^{2h(X | U_k, Q)} &\geq 2^{2h\left(\frac{\sigma_X^2}{\sigma_X^2 + \sigma_{N_k}^2} Y_k | U_k, Q\right)} + 2^{2h(N'_k | U_k, Q)} \\ &= \left(\frac{\sigma_X^2}{\sigma_X^2 + \sigma_{N_k}^2} \right)^2 2^{2h(Y_k | U_k, Q)} + 2\pi e \left(\frac{\sigma_X^2 \sigma_{N_k}^2}{\sigma_X^2 + \sigma_{N_k}^2} \right). \end{aligned}$$

Now using the condition (63) and after some algebras, it holds that

$$2^{2h(Y_k | U_k, Q)} \leq 2\pi e \left(\frac{\beta_k (\sigma_X^2 + \sigma_{N_k}^2)}{\sigma_X^2 + \sigma_{N_k}^2 + \beta_k} \right). \quad (65)$$

Therefore,

$$h(Y_k | U_k, Q) \leq \frac{1}{2} \log 2\pi e \left(\frac{\beta_k (\sigma_X^2 + \sigma_{N_k}^2)}{\sigma_X^2 + \sigma_{N_k}^2 + \beta_k} \right), \quad (66)$$

and combining the condition in (63) with (66) yields

$$\begin{aligned}
& I(Y_k; U_k | X, Q) \\
&= h(Y_k) - h(Y_k | U_k, Q) - h(X) + h(X | U_k, Q) \\
&\geq \frac{1}{2} \log 2\pi e \left(\frac{\sigma_X^2 + \sigma_{N_k}^2}{\sigma_X^2} \right) - \frac{1}{2} \log 2\pi e \left(\frac{\beta_k (\sigma_X^2 + \sigma_{N_k}^2)}{\sigma_X^2 + \sigma_{N_k}^2 + \beta_k} \right) \\
&\quad - \frac{1}{2} \log 2\pi e \sigma_X^2 + \frac{1}{2} \log 2\pi e \left(\frac{\sigma_X^2 (\sigma_{N_k}^2 + \beta)}{\sigma_X^2 + \sigma_{N_k}^2 + \beta} \right) \\
&= \frac{1}{2} \log \left(\frac{\sigma_{N_k}^2 + \beta}{\beta} \right) = r_k. \tag{67}
\end{aligned}$$

Finally, putting (62) and (67) into the constraints in (25)–(33), the converse proof of Theorem 4 completes. \square

APPENDIX C PROOF OF PROPOSITION 4

Assume that a rate tuple $(R_1, R_2, L_1, L_2, D) \in \mathbb{R}_+^5$ is achievable with respect to Definition 1. Define

$$V_{k,t} = (J_k, Y_k^{t-1}), \quad U_{k,t} = (J_k, Y_k^{t-1}, X^{t-1}), \quad Q_t = X^{n \setminus t} \tag{68}$$

for $k \in \{1, 2\}$. Note that conditioned on Q_t , the random variables $V_{1,t}, U_{1,t}, Y_{1,t}, X_t, Z_t, Y_{2,t}, U_{2,t}$, and $V_{2,t}$ satisfy all possible Markov chains defined by (14).

In the following lemma, we derive a lower bound on the term $-I(Z^n; J_k)$ for the settings in (68) via Lemma 1.

Lemma 3. Define $\xi'_t = I(V_{1,t}; V_{2,t} | Q_t)$. It holds that

$$-I(Z^n; J_k) \geq \sum_{t=1}^n \{I(V_{k,t}; U_{k',t} | Q_t) - I(Z_t; V_{k,t} | Q_t) - \xi'_t\}. \tag{69}$$

Proof: From the same development to derive (43), we have

$$\begin{aligned}
I(J_k; J_{k'}) - I(Z^n; J_k) &= \sum_{t=1}^n \{H(Y_{k,t} | Z_t) \\
&\quad - H(Y_{k,t} | J_k, Y_k^{t-1}, Z^n) - H(Y_{k,t}, Y_{k',t} | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) \\
&\quad + H(Y_{k,t}, Y_{k',t} | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1})\} \\
&= \sum_{t=1}^n \{H(Y_{k,t} | Z_t) - H(Y_{k,t} | J_k, Y_k^{t-1}, Z^n, Q_t) \\
&\quad - I(Q_t; Y_{k,t} | J_k, Z^n, Y_k^{t-1}) \\
&\quad - H(Y_{k,t}, Y_{k',t} | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, Q_t) \\
&\quad - I(Q_t; Y_{k,t}, Y_{k',t} | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) \\
&\quad + H(Y_{k,t}, Y_{k',t} | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, Q_t) \\
&\quad + I(Q_t; Y_{k,t}, Y_{k',t} | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1})\} \\
&\stackrel{(a)}{\geq} \sum_{t=1}^n \{H(Y_{k,t} | Z_t, Q_t) - H(Y_{k,t} | V_{k,t}, Z_t, Q_t) \\
&\quad - H(Y_{k,t}, Y_{k',t} | U_{k',t}, Q_t) + H(Y_{k,t}, Y_{k',t} | V_{k,t}, U_{k',t}, Q_t) \\
&\quad - I(Q_t; Y_{k,t} | J_k, Z^n, Y_k^{t-1}) \\
&\quad - I(Q_t; Y_{k,t}, Y_{k',t} | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) \\
&\quad + I(Q_t; Y_{k,t}, Y_{k',t} | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1})\} \\
&\geq \sum_{t=1}^n \{I(V_{k,t}; U_{k',t} | Q_t) - I(Z_t; V_{k,t} | Q_t)\} + F \tag{70}
\end{aligned}$$

with

$$\begin{aligned}
F &\equiv \sum_{t=1}^n \{-I(Q_t; Y_{k,t} | J_k, Z^n, Y_k^{t-1}) \\
&\quad - I(Q_t; Y_{k,t}, Y_{k',t} | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) \\
&\quad + I(Q_t; Y_{k,t}, Y_{k',t} | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1})\},
\end{aligned}$$

where (a) follows since conditioning reduces entropy and (b) follows from the Markov chain $Y_{k,t} - (J_k, Y_k^{t-1}, Z_t, Q_t) - Z^{n \setminus t}$ and the steps from (44) to (45) since the conditional mutual information $I(V_{k,t}; U_{k',t} | Y_{k,t}, Y_{k',t}, Q_t) = 0$.

Observe that F can be expressed as in (71) at the top of the next page, where (a) holds due to the Markov chains $Y_{k,t} - (J_k, Y_k^{t-1}, Z^n) - X^{t-1}$, $(Y_{k,t}, Y_{k',t}) - (J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) - X^{t-1}$ and $(Y_{k,t}, Y_{k',t}) - (J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) - X^{t-1}$, (b) follows from the Csiszár sum identify [48, Ch. 2], and (c) is due to reordering of the terms.

For the first summation in (71), it holds that

$$\begin{aligned}
& \sum_{t=1}^n \{-H(X_t | Z_t) + H(X_t | J_k, Y_k^{t-1}, X_{t+1}^n, Z^n) \\
&\quad - H(X_t) + H(X_t | J_{k'}, Y_{k'}^{t-1}, Y_{k'}^{t-1}, X_{t+1}^n) \\
&\quad + H(X_t | J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n) \\
&\quad - H(X_t | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, X_{t+1}^n)\} \\
&\stackrel{(a)}{=} \sum_{t=1}^n \{-H(X_t | Z_t) + H(X_t | J_k, Y_k^{t-1}, Z_t, Q_t) \\
&\quad - H(X_t) + H(X_t | J_{k'}, Y_{k'}^{t-1}, Q_t) \\
&\quad + H(X_t | J_{k'}, Y_{k'}^{t-1}, Q_t) \\
&\quad - H(X_t | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, Q_t)\} \\
&= \sum_{t=1}^n \{-H(X_t | Z_t) + H(X_t | V_{k,t}, Q_t, Z_t) - H(X_t) \\
&\quad + H(X_t | V_{k',t}, Q_t) + H(X_t | V_{k',t}, Q_t) \\
&\quad - H(X_t | V_{k,t}, V_{k',t}, Q_t)\} \\
&= \sum_{t=1}^n \{-I(X_t; V_{k,t} | Z_t, Q_t) - I(X_t; V_{k',t} | Q_t) \\
&\quad + I(X_t; V_{k,t} | V_{k',t}, Q_t)\} \\
&= \sum_{t=1}^n \{I(Z_t; V_{k,t} | Q_t) - I(X_t; V_{k',t} | Q_t) - I(V_{k,t}; V_{k',t} | Q_t)\} \\
&= \sum_{t=1}^n \{I(Z_t; V_{k,t} | Q_t) - I(X_t; V_{k',t} | Q_t) - \xi'_t\}, \tag{72}
\end{aligned}$$

where (a) holds due to the following Markov chains:

$$X_t - (J_k, Y_k^{t-1}, Z^n, X_{t+1}^n) - X^{t-1}, \tag{73}$$

$$X_t - (J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n) - Y_{k'}^{t-1}, \tag{74}$$

$$X_t - (J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, X_{t+1}^n) - X^{t-1}. \tag{75}$$

Note that as a particular case of (75), we also have $X_t - (J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n) - X^{t-1}$.

$$\begin{aligned}
F &\stackrel{(a)}{=} \sum_{t=1}^n \{-I(X_{t+1}^n; Y_{k,t} | J_k, Z^n, Y_k^{t-1}) - I(X_{t+1}^n; Y_{k,t}, Y_{k',t} | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}) + I(X_{t+1}^n; Y_{k,t}, Y_{k',t} | J_k, J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1})\} \\
&\stackrel{(b)}{=} \sum_{t=1}^n \{-I(X_t; Y_k^{t-1} | J_k, X_{t+1}^n, Z^n) - I(X_t; Y_k^{t-1}, Y_{k'}^{t-1} | J_{k'}, X_{t+1}^n) + I(X_t; Y_k^{t-1}, Y_{k'}^{t-1} | J_k, J_{k'}, X_{t+1}^n)\} \\
&= \sum_{t=1}^n \{-H(X_t | J_k, X_{t+1}^n, Z^n) + H(X_t | J_k, Y_k^{t-1}, X_{t+1}^n, Z^n) - H(X_t | J_{k'}, X_{t+1}^n) + H(X_t | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, X_{t+1}^n) \\
&\quad + H(X_t | J_k, J_{k'}, X_{t+1}^n) - H(X_t | Y_k^{t-1}, Y_{k'}^{t-1}, J_k, J_{k'}, X_{t+1}^n)\} \\
&= \sum_{t=1}^n \{I(X_t; J_k | X_{t+1}^n, Z^n) - H(X_t | Z_t) + H(X_t | J_k, Y_k^{t-1}, X_{t+1}^n, Z^n) + I(X_t; J_{k'} | X_{t+1}^n) - H(X_t) \\
&\quad + H(X_t | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, X_{t+1}^n) + I(X_t; Y_{k'}^{t-1} | J_k, J_{k'}, X_{t+1}^n) - I(X_t; J_k | J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n) + H(X_t | J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n) \\
&\quad - H(X_t | Y_k^{t-1}, Y_{k'}^{t-1}, J_k, J_{k'}, X_{t+1}^n)\} \\
&\stackrel{(c)}{=} \sum_{t=1}^n \{-H(X_t | Z_t) + H(X_t | J_k, Y_k^{t-1}, X_{t+1}^n, Z^n) - H(X_t) + H(X_t | J_{k'}, Y_k^{t-1}, Y_{k'}^{t-1}, X_{t+1}^n) \\
&\quad + H(X_t | J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n) - H(X_t | Y_k^{t-1}, Y_{k'}^{t-1}, J_k, J_{k'}, X_{t+1}^n)\} + \sum_{t=1}^n \{I(X_t; J_k | X_{t+1}^n, Z^n) \\
&\quad + I(X_t; J_{k'} | X_{t+1}^n) + I(X_t; Y_{k'}^{t-1} | J_k, J_{k'}, X_{t+1}^n) - I(X_t; J_k | J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n)\} \tag{71}
\end{aligned}$$

For the second summation in (71), it follows that

$$\begin{aligned}
&\sum_{t=1}^n \{I(X_t; J_k | X_{t+1}^n, Z^n) + I(X_t; J_{k'} | X_{t+1}^n) \\
&\quad + I(X_t; Y_k^{t-1} | J_k, J_{k'}, X_{t+1}^n) - I(X_t; J_k | J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n)\} \\
&= \sum_{t=1}^n \{I(X_t; J_k | X_{t+1}^n, Z^n) + I(X_t; J_{k'} | X_{t+1}^n) \\
&\quad + H(X_t | J_k, J_{k'}, X_{t+1}^n) - H(X_t | J_{k'}, Y_{k'}^{t-1}, X_{t+1}^n)\} \\
&= \sum_{t=1}^n \{I(X_t; J_k | X_{t+1}^n, Z^n) + I(X_t; J_{k'} | X_{t+1}^n) \\
&\quad + H(X_t | J_k, J_{k'}, X_{t+1}^n) - H(X_t | V_{k',t}, Q_t)\} \\
&= \sum_{t=1}^n \{-I(X_t; Z_t) + I(X_t; Z^n | J_k, X_{t+1}^n) \\
&\quad + I(X_t; V_{k',t} | Q_t)\} + I(X^n; J_k) - I(X^n; J_k | J_{k'}) \\
&\stackrel{(a)}{\geq} \sum_{t=1}^n \{-I(X_t; Z_t) + I(X_t; Z_t | J_k, X_{t+1}^n) \\
&\quad + I(X_t; V_{k',t} | Q_t)\} + I(J_k; J_{k'}) \\
&\stackrel{(b)}{=} \sum_{t=1}^n \{-H(Z_t) + H(Z_t | J_k, X_{t+1}^n) \\
&\quad + I(X_t; V_{k',t} | Q_t)\} + I(J_k; J_{k'}) \\
&\stackrel{(c)}{\geq} \sum_{t=1}^n \{-H(Z_t) + H(Z_t | J_k, Y_k^{t-1}, Q_t) \\
&\quad + I(X_t; V_{k',t} | Q_t)\} + I(J_k; J_{k'}) \\
&= \sum_{t=1}^n \{-I(Z_t; V_{k,t} | Q_t) + I(X_t; V_{k',t} | Q_t)\} + I(J_k; J_{k'}), \tag{76}
\end{aligned}$$

where (a) is due to the Markov chain $J_k - X^n - J_{k'}$, (b) is due to the Markov chain $Z_t - X_t - (J_k, X_{t+1}^n)$, and (c) follows since conditioning reduces entropy. Substituting (72) and (76) into (71), it follows that

$$F \geq - \sum_{t=1}^n \xi'_t + I(J_k; J_{k'}). \tag{77}$$

Lastly, plugging (77) into (70), (69) is obtained. \square

For the choice of $V_{k,t}, U_{k,t}$ in (68), (56)–(59) also hold, i.e.,

$$H(J_k | X^n) = \sum_{t=1}^n I(Y_{k,t}; U_{k,t} | X_t, Q_t), \tag{78}$$

$$\begin{aligned}
n \left(\sum_{k \in \mathcal{S}} R_k + 2\delta \right) &\geq H(J_{\mathcal{S}}) \geq \sum_{t=1}^n \{H(X_t | U_{\mathcal{S}^c,t}, Q_t)\} \\
&\quad + \sum_{k \in \mathcal{S}} \left\{ \sum_{t=1}^n I(Y_{k,t}; U_{k,t} | X_t, Q_t) \right\} - n(D + \delta), \tag{79}
\end{aligned}$$

$$n(D + \delta) \geq \sum_{t=1}^n H(X_t | U_{1,t}, U_{2,t}, Q_t). \tag{80}$$

The analyses of the privacy-leakage rates, their sum rate, and the mixed sum rate are verified as follows:

i) *Analysis of the Privacy-Leakage Rate:* From the same steps to derive (48), we have

$$\begin{aligned}
n(L_k + \delta) &\geq H(J_k) - H(X^n; J_k) - I(Z^n; J_k) \\
&\stackrel{(a)}{\geq} \sum_{t=1}^n \{H(X_t | U_{k',t}, Q_t) - (D + \delta)\} - I(Z^n; J_k) \\
&\stackrel{(b)}{\geq} \sum_{t=1}^n \{H(X_t | U_{k',t}, Q_t) - (D + \delta) + I(V_{k,t}; U_{k',t} | Q_t) \\
&\quad - I(Z_t; V_{k,t} | Q_t) - \xi'_t\}, \tag{81}
\end{aligned}$$

where (a) is due to (78) and (79) with $\mathcal{S} = \{k\}$ and $\mathcal{S}^c = \{k'\}$, and (b) follows since Lemma 3 applies.

ii) *Analysis of the Sum Rate:* Again from (50), it follows that

$$\begin{aligned}
& n(L_1 + L_2 + 2\delta) \\
& \geq I(X^n; J_1) + I(X^n; J_2) - I(Z^n; J_1) - I(Z^n; J_2) \\
& = H(J_1) + H(J_2) - H(J_1|X^n) - H(J_2|X^n) \\
& \quad - I(Z^n; J_1) - I(Z^n; J_2) \\
& \geq H(J_1, J_2) - H(J_1|X^n) - H(J_2|X^n) \\
& \quad - I(Z^n; J_1) - I(Z^n; J_2) \\
& \stackrel{(a)}{\geq} \sum_{t=1}^n \{H(X_t) - (D + \delta)\} - I(Z^n; J_1) - I(Z^n; J_2) \\
& \stackrel{(b)}{\geq} \sum_{t=1}^n \{H(X_t) - (D + \delta) + I(V_{1,t}; U_{2,t}|Q_t) - I(Z_t; V_{1,t}|Q_t) \\
& \quad + I(V_{2,t}; U_{1,t}|Q_t) - I(Z_t; V_{2,t}|Q_t) - 2\xi'_t\} \\
& \geq \sum_{t=1}^n \{H(X_t) - (D + \delta) + I(V_{1,t}; V_{2,t}|Q_t) - I(Z_t; V_{1,t}|Q_t) \\
& \quad - I(Z_t; V_{2,t}|Q_t) - \xi'_t\}, \tag{82}
\end{aligned}$$

where (a) follows from (78) and (79) for $\mathcal{S} = \{1, 2\}$ and (b) is due to Lemma 3.

iii) *Analysis of the Mixed Sum Rate:* As in (54),

$$\begin{aligned}
& n(R_{k'} + L_k + 2\delta) \geq H(J_{k'}, J_k) - H(J_k|X^n) - I(Z^n; J_k) \\
& \stackrel{(a)}{\geq} \sum_{t=1}^n \{I(Y_{k',t}; U_{k',t}|X_t, Q_t) + H(X_t) - (D + \delta) \\
& \quad - I(Z_t; J_k|Z^{t-1})\} \\
& \geq \sum_{t=1}^n \{I(Y_{k',t}; U_{k',t}|X_t, Q_t) + H(X_t) - (D + \delta) \\
& \quad - I(Z_t; J_k, Y_k^{t-1}, Q_t, Z^{t-1})\} \\
& \stackrel{(b)}{=} \sum_{t=1}^n \{I(Y_{k',t}; U_{k',t}|X_t, Q_t) + H(X_t) - (D + \delta) \\
& \quad - I(Z_t; V_{k,t}|Q_t)\}, \tag{83}
\end{aligned}$$

where (a) follows from (78) and (79) for $\mathcal{S} = \{k, k'\}$ and $\mathcal{S}^c = \emptyset$ and (b) is due to the i.i.d. property of (X^n, Z^n) .

The proof is wrapped up by applying the standard single-letterization argument and the support lemma together with the Fenchel-Eggleston-Carathéodory theorem [48] to bound the cardinalities of $\mathcal{V}_k, \mathcal{U}_k$, and \mathcal{Q} . Finally, the converse proof is completed by letting $n \rightarrow \infty$ and $\delta \downarrow 0$. \square

APPENDIX D A COUNTEREXAMPLE

In this appendix, we show that the inner and outer bounds on the rate-distortion-equivocation region under the log-loss do not coincide. From [43, Equations (84)–(92)], the inner bound is given by the closure of the set of all tuples

$(R_1, R_2, \Delta_1, \Delta_2, D) \in \mathbb{R}_+^5$, where Δ_1, Δ_2 denote the equivocation rates as in [43], satisfying

$$\begin{aligned}
& R_1 \geq I(Y_1; \tilde{U}_1|\tilde{U}_2, Q), \quad R_2 \geq I(Y_2; \tilde{U}_2|\tilde{U}_1, Q), \\
& R_1 + R_2 \geq I(Y_1, Y_2; \tilde{U}_1, \tilde{U}_2|Q), \\
& \Delta_1 \leq H(X) - I(X; \tilde{U}_1|\tilde{U}_2, Q), \\
& \Delta_2 \leq H(X) - I(X; \tilde{U}_2|\tilde{U}_1, Q), \\
& \Delta_1 + \Delta_2 \leq H(X) + H(X|\tilde{U}_1, \tilde{U}_2, Q), \\
& \Delta_2 - R_1 \leq H(X) - I(Y_1, X; \tilde{U}_1, \tilde{U}_2|Q), \\
& \Delta_1 - R_2 \leq H(X) - I(X, Y_2; \tilde{U}_1, \tilde{U}_2|Q), \\
& D \geq H(X|\tilde{U}_1, \tilde{U}_2, Q) \tag{84}
\end{aligned}$$

for a joint distribution

$$P_X(x)P_Q(q) \prod_{k=1}^2 P_{Y_k|X}(y_k|x)P_{\tilde{U}_k|Y_k Q}(\tilde{u}_k|y_k, q) \tag{85}$$

with $|\tilde{\mathcal{U}}_k| \leq |\mathcal{Y}_k| + 4$ and $|Q| \leq 6$.

By a similar argument shown in Appendix B with defining $\tilde{U}_{1,t} = (J_1, Y_1^{t-1})$, $\tilde{U}_{2,t} = (J_2, Y_2^{t-1})$, and $Q_t = X^{n \setminus t}$, the outer bound is characterized by the closure of the set of all tuples $(R_1, R_2, \Delta_1, \Delta_2, D) \in \mathbb{R}_+^5$ satisfying

$$\begin{aligned}
& R_1 \geq I(Y_1; \tilde{U}_1|X, Q) + H(X|\tilde{U}_2, Q) - D, \\
& R_2 \geq I(Y_2; \tilde{U}_2|X, Q) + H(X|\tilde{U}_1, Q) - D, \\
& R_1 + R_2 \geq I(Y_1; \tilde{U}_1|X, Q) + I(Y_2; \tilde{U}_2|X, Q) + H(X) - D, \\
& \Delta_1 \leq H(X) - H(X|\tilde{U}_2, Q) + D, \\
& \Delta_2 \leq H(X) - H(X|\tilde{U}_1, Q) + D, \\
& \Delta_1 + \Delta_2 \leq H(X) + D, \\
& \Delta_2 - R_1 \leq -I(Y_1; \tilde{U}_1|X, Q) + D, \\
& \Delta_1 - R_2 \leq -I(Y_2; \tilde{U}_2|X, Q) + D, \\
& D \geq H(X|\tilde{U}_1, \tilde{U}_2, Q) \tag{86}
\end{aligned}$$

for a joint distribution defined in (85) with $|\tilde{\mathcal{U}}_k| \leq |\mathcal{Y}_k| + 1$ and $|Q| \leq 6$.

Suppose that the rate-distortion-equivocation is tight, i.e., the inner bound defined in (84) matches the outer bound defined in (86). However, for the regions in (84) and (86), a counterexample can be easily found as follows: For the extreme point where $D = I(Y_1; \tilde{U}_1|X, Q) + H(X|\tilde{U}_2, Q)$ (the minimum value of R_1 is zero), the right-hand side of the constraint for Δ_1 in (86) becomes

$$\begin{aligned}
& \Delta_1 \leq H(X) - H(X|\tilde{U}_2, Q) + D \\
& \quad = H(X) + I(Y_1; \tilde{U}_1|X, Q),
\end{aligned}$$

which is greater than $H(X)$, the maximum achievable quantity of Δ_1 in the inner bound when we set both \tilde{U}_1 and \tilde{U}_2 to be constant. This implies that there may exist some rate tuple $(R_1, R_2, \Delta_1, \Delta_2, D)$ in the outer bound which is not contained in the inner bound. \square

$$\begin{aligned}
P_1 &= (0, 0, 0, 0, I(Y_1; U_1|X, Q) + I(Y_2; U_2|X, Q) + H(X)), \\
P_2 &= (0, I(Y_2; U_2|X, Q), 0, 0, I(Y_1; U_1|X, Q) + H(X)), \\
P_3 &= (I(Y_1; U_1|X, Q), 0, 0, 0, I(Y_2; U_2|X, Q) + H(X)), \\
P_4 &= (I(Y_1; U_1|X, Q), I(Y_2; U_2|X, Q), 0, 0, H(X)), \\
P_5 &= (0, I(Y_2; U_2|Q), 0, I(X; U_2|Q), I(Y_1; U_1|X, Q) + H(X|U_2, Q)), \\
P_6 &= (I(Y_1; U_1|Q), 0, I(X; U_1|Q), 0, I(Y_2; U_2|X, Q) + H(X|U_1, Q)), \\
P_7 &= (I(Y_1; U_1|X, Q), I(Y_2; U_2|Q), 0, I(X; U_2|Q), H(X|U_2, Q)), \\
P_8 &= (I(Y_1; U_1|Q), I(Y_2; U_2|X, Q), I(X; U_1|Q), 0, H(X|U_1, Q)), \\
P_9 &= (I(Y_1; U_1|Q), I(Y_2; U_2|U_1, Q), I(X; U_1|Q), I(X; U_2|U_1, Q), H(X|U_1, U_2, Q)), \\
P_{10} &= (I(Y_1; U_1|U_2, Q), I(Y_2; U_2, Q), I(X; U_1|U_2, Q), I(X; U_2|Q), H(X|U_1, U_2, Q)),
\end{aligned} \tag{87}$$

APPENDIX E REGION EQUIVALENCE

In this appendix, we show that the inner bound $\mathcal{R}_{\text{in}}^L$ in Proposition 1 matches the outer bound $\mathcal{R}_{\text{out}}^L$ in Proposition 2. We prove this corollary without caring about the cardinality bounds on the auxiliary RVs U_1, U_2 , and the time-sharing variable Q since they are obtainable by independent arguments.

It is sufficient to show the relationship $\mathcal{R}_{\text{in}}^L \supseteq \mathcal{R}_{\text{out}}^L$ in the proof since we have already demonstrated in Appendix B that every achievable tuple with respect to Definition 1 is contained in the region $\mathcal{R}_{\text{out}}^L$. By the same approach in [27], for $j \in [1 : 10]$, we say that a point $P_j = (R_1^{(j)}, R_2^{(j)}, K_1^{(j)}, K_2^{(j)}, D^{(j)}) \in \mathcal{R}_{\text{out}}^L$ is dominated by a point $\mathcal{R}_{\text{in}}^L$ if there exists some $(R_1, R_2, K_1, K_2, D) \in \mathcal{R}_{\text{in}}^L$ for which $R_1 \leq R_1^{(j)}$, $R_2 \leq R_2^{(j)}$, $K_1 \leq K_1^{(j)}$, $K_2 \leq K_2^{(j)}$, and $D \leq D^{(j)}$. Fixing $P_Q, P_{U_1|Y_1Q}$, and $P_{U_2|Y_2Q}$, the extreme points of the polytope defined by the constraints in $\mathcal{R}_{\text{out}}^L$ are listed in (87) at the top of this page, where the points P_1, \dots, P_8 correspond to the endpoints when the constraints $R_1 + R_2, R_1 + K_2, R_2 + K_1, K_1 + K_2, R_1, R_2, K_1$, and K_2 in $\mathcal{R}_{\text{out}}^L$ become zero, respectively, and P_9 and P_{10} are attained when the distortion constraint is optimal.

Note that the points P_9 and P_{10} lie in the region $\mathcal{R}_{\text{in}}^L$. Now observe that the point $(0, 0, 0, 0, H(X))$ is in $\mathcal{R}_{\text{in}}^L$, obtained by setting U_1 and U_2 to be constant, and this point dominates the points P_1, P_2, P_3 , and P_4 . In case of setting only U_1 to be constant, the point

$$(0, I(Y_2; U_2|Q), 0, I(X; U_2|Q), H(X|U_2, Q))$$

is in $\mathcal{R}_{\text{in}}^L$ and dominates P_5 and P_7 . Moreover, by setting U_2 to be constant, we have that the point

$$(I(Y_1; U_1|Q), 0, I(X; U_1|Q), 0, H(X|U_1, Q))$$

is included in $\mathcal{R}_{\text{in}}^L$, which dominates P_6 and P_8 . Since $\mathcal{R}_{\text{out}}^L$ is the convex hull of these extreme points P_1, \dots, P_{10} , it is guaranteed that the region $\mathcal{R}_{\text{in}}^L$ contains $\mathcal{R}_{\text{out}}^L$. \square
