The standard model (SM) one-loop contributions to the most general $H^*Z^*Z^*$ coupling are obtained via the background field method in terms of Passarino-Veltman scalar functions, from which the contributions to the H^*ZZ and HZZ^* couplings are obtained in terms of two CP-conserving $h_{1,2}^V$ and one *CP*-violating h_3^V form factors (V = H, Z). The current CMS constraints on the HZZcoupling ratios are then used to obtain bounds on the real and absorptive parts of the anomalous HZZ couplings. The former are up to two orders of magnitude tighter than previous ones, whereas the latter are the first one of this kind. The effects of the absorptive parts of the HZZ anomalous couplings, which have been overlooked in the past, are analyzed via the partial decay width $\Gamma_{H^* \to ZZ}$, and a significant deviation from the SM tree-level contribution is observed at low energies, though it becomes negligible at high energies. We also explore the possibility that polarized Z gauge bosons are used for the study of non-SM HZZ contributions via a new left-right asymmetry \mathcal{A}_{LR} , which is sensitive to CP-violating complex form factors and can be as large as the unity at most, though in a more conservative scenario it is four to five orders of magnitude larger than the SM prediction arising up to the three-loop level. The partial decay widths $\Gamma_{H^* \to Z_L Z_L}$ and $\Gamma_{H^* \to Z_R Z_R}$ are also studied in several scenarios and it is observed that the deviations from the SM can be large at high energies and increases as the energy increases. Thus, the use of polarized Z gauge bosons could give hints of CP violation. The Mathematica code for our analytical results and the numerical evaluation is available in our GitLab site.

I. INTRODUCTION

The observation of the Higgs boson at the CERN LHC [1, 2] was clear evidence that the mechanism of electroweak gauge symmetry breaking is realized in nature as conjectured by the Glashow-Weinberg-Salam Standard Model (SM) of elementary particles. Up to now, the data collected at the LHC has confirmed that the properties of the Higgs particle are consistent with the SM, though some of its couplings are yet to be measured, such as those to light fermions and its self-couplings as well. It is expected that the LHC Run 3 can also explore hints of some anomalous Higgs couplings. Along these lines, the CMS collaboration has reported for the first time data on the off-shell H^*ZZ coupling via off-shell Higgs boson production (O-SHBP) $pp \rightarrow H^* \rightarrow ZZ$ [3], which requires that the four-momentum of the off-shell Higgs boson is above the threshold $||q|| = 2m_Z$. According to the SM, 10% of V-pair production events at the LHC are due to the H^*VV coupling [4], which is statistically large enough to allow measurement. Moreover, it has been found that the VV invariant mass kinematic distribution is sensitive to the off-shell H^*ZZ contribution, whereas the ratio of off-shell to on-shell production rates can be used to determine the Higgs decay width Γ_H [5, 6].

The phenomenological and experimental implications of the H^*ZZ coupling at the LCH and future colliders have been explored in the past and also very recently [7–15]. Furthermore, the off-shell HZZ^* coupling has several phenomenological implications, which have been studied through HZ production [16–34]. Thus, the HZZ coupling is worth studying, thereby requiring a highly precise determination of all its lowest-order contributions. In particular, the search for any anomalous contribution to the H^*ZZ coupling is expected to play an important role in the LHC future program.

Off-shell couplings have been of great interest in recent years [35–37] as they can develop an imaginary (absorptive) part because of the optical theorem, thereby giving rise to interesting effects in physical processes. Such class of effects have already been studied by some of us, for instance, in the off-shell chromomagnetic and chromoeletric dipole moments of quarks [38, 39] and also in the trilinear neutral gauge boson couplings [40, 41]. The latter require that at least one of the three gauge bosons is off-shell to be non-vanishing [42, 43]. On the other hand, the phenomenological implications of the absorptive part of the off-shell Higgs boson coupling H^*ZZ have been brought to attention by many authors [18, 20, 22, 28], nonetheless, to our knowledge, a precise determination of the SM contribution has not been reported yet, which may stem from the fact that there has been some controversy on whether or not off-shell couplings represent valid observable quantities, but we will dwell on this issue below. The study of the absorptive part of the H^*ZZ and HZZ^* couplings may be relevant at the LHC and future colliders as it can explain slight deviations on some physical observables, such as in the case of the absorptive part of the ttg coupling, which has direct effects on top pair production at the LHC [37].

The one-loop corrections to the HZZ coupling were calculated long ago in the SM [44, 45] and also recently

[46], whereas new physics contributions have been reported in several SM extensions, such as the two-Higgs doublet model [47], the minimal Higgs triplet model (HTM) [48], the Higgs singlet model (HSM) [47], and the minimal supersymmetric standard model (MSSM) [36]. Nevertheless, some of those results were reported in a somewhat oldfashioned notation, which could lead to some confusion if a numerical calculation is required to cross check results. Therefore, a new evaluation of the SM one-loop contributions to the off-shell H^*ZZ coupling with a more up-to-date notation for the analytical results is in order. The purpose of this work is to present such an evaluation. Afterwards, we will use our analytical results and the current LHC data to obtain limits on the real and absorptive parts of the anomalous couplings of the HZZ vertex. These new bounds can be relevant because of the O-SHBP results. Furthermore, their implications could be observed in Z boson pair production.

The rest of this work is organized as follows. In Section II we analyze the most general effective Lagrangian for the HZZ coupling up to dimension-six operators, along with a short discussion on the most popular parametrizations used to study the effects of this coupling at particle colliders, with some lengthy formulas used in the derivation of such parametrizations being presented in Appendix A. Section III is devoted to the calculation of the SM one-loop contributions to the off-shell H^*ZZ and HZZ^* couplings via the background field method, which in the Feynman-t'Hooft gauge yields identical results to those obtained via the Pinch technique. Both methods are known to lead to gauge-independent and ultraviolet finite off-shell Green's functions. The analytical results are presented in Appendix B in terms of Passarino-Veltman scalar functions. In Section IV we present the numerical analysis of the behavior of the H^*ZZ and HZZ^* couplings as functions of the off-shell boson transfer momentum, whereas in Sec. V we obtain bounds on the anomalous contributions. The results are used in Sec. VI to study Z pair production off an off-shell Higgs boson at the LHC, for which we introduce a new asymmetry defined for polarized Z gauge bosons. Finally, in Section VII we present the conclusions and outlook.

II. THEORETICAL FRAMEWORK

Several parametrizations have been introduced in the literature to study the phenomenology of the HZZ coupling. It is thus worth presenting an overview of the most popular of such parametrizations and the corresponding limits from experimental data with the aim that our analysis can be straightforwardly compared with similar studies if required.

A. Hagiwara Basis

First of all, the effective Lagrangian up to dimension-six operators for the HZZ interaction can be written in the so-called Hagiwara basis [17, 18, 23] as follows

$$\mathcal{L}^{HZZ} = \frac{g}{c_W} m_Z \Big[\frac{(1-a_Z)}{2} H Z_\mu Z^\mu + \frac{1}{2m_Z^2} \Big\{ b_Z H Z_{\mu\nu} Z^{\mu\nu} + c_Z \Big(\big(\partial_\mu H \big) Z_\nu - \big(\partial_\nu H \big) Z_\mu \Big) Z^{\mu\nu} + \widetilde{b}_Z H Z_{\mu\nu} \widetilde{Z}^{\mu\nu} \Big\} \Big], \quad (1)$$

where $Z_{\mu\nu} = \partial_{\mu}Z_{\nu} - \partial_{\nu}Z_{\mu}$ and $\tilde{Z}_{\mu\nu} = \epsilon_{\mu\nu\alpha\beta}Z^{\alpha\beta}/2$. In the SM, the a_Z , b_Z , c_Z and \tilde{b}_Z form factors vanish at the tree level, but they can receive contributions at higher orders of perturbation theory. While the *CP* conserving form factors b_Z and c_Z are induced at the one-loop level in the SM [45], the *CP* violating form factor \tilde{b}_Z arises up to the three-loop level [7] and its magnitude has been estimated to be of the order of 10^{-11} [49]. Anomalous contributions to the b_Z , c_Z and \tilde{b}_Z form factors can also arise from new physics theories at the one-loop-level or higher orders of perturbation theory. In Fig. 1, we introduce the notation used throughout the rest of this work for the vertex function $\Gamma_{\mu\nu}^{ZZH}$.

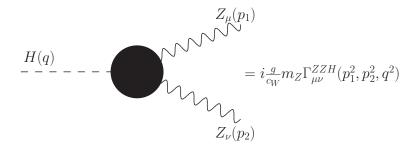

FIG. 1. Nomenclature for the HZZ coupling and the $\Gamma^{ZZH}_{\mu\nu}$ vertex function.

Although we are mainly interested in processes where the Higgs boson is off-shell, namely, those induced by the H^*ZZ coupling, for completeness we will also study the HZZ^* coupling, which has also been widely studied in the literature as it has several implications at particle colliders [16–33]. Furthermore, we will consider that the Z gauge bosons are coupled to conserved currents, thus in Eq. (1), we drop the longitudinal component of the Z gauge bosons by setting $\partial_{\mu}Z^{\mu} = 0$.

We now denote the off-shell boson by V and consider the kinematics $H \to ZZ \ (Z \to HZ)$ for V = H(Z) along with the notation of Fig. 1 to obtain the corresponding vertex function:

$$\Gamma_{\mu\nu}^{ZZH}(p_1^2, p_2^2, q^2) = h_1^V(q^2, p_1^2, p_2^2)g_{\mu\nu} + \frac{h_2^V(q^2, p_1^2, p_2^2)}{m_Z^2}p_{1\nu}p_{2\mu} + \frac{h_3^V(q^2, p_1^2, p_2^2)}{m_Z^2}\epsilon_{\mu\nu\alpha\beta}p_1^{\alpha}p_2^{\beta}, \tag{2}$$

where the dependence of the h_i^V form factors have been written out explicitly. The relations between the form factors h_i^V and the parameters of Lagrangian (1) for V = H(Z) are

$$h_1^V(q^2, p_1^2, p_2^2) = 1 + a_Z - b_Z \frac{q^2 - p_1^2 - p_2^2}{m_Z^2} + c_Z \frac{q^2}{m_Z^2},$$
(3)

$$h_2^V(q^2, p_1^2, p_2^2) = \pm 2(b_Z - c_Z), \tag{4}$$

$$h_{2}^{V}(q^{2}, p_{1}^{2}, p_{2}^{2}) = \pm 2\widetilde{b}_{Z},$$
(1)

$$h_{3}^{V}(q^{2}, p_{1}^{2}, p_{2}^{2}) = \pm 2\widetilde{b}_{Z},$$
(5)

where $p_1^2 = m_Z^2$ $(q^2 = m_H^2)$ for V = H(Z), and $p_2^2 = m_Z^2$ in either case.

Note that the structure of Eq. (2) is the same for one, two, and three off-shell particles as long as both Z gauge bosons are coupled to conserved currents. It is also worth noticing that the basis used in the Lagrangian (1) is not unique. In fact, the use of the equations of motion leads to the following alternative form for the Lagrangian of the HZZ coupling

$$\mathcal{L}^{HZZ} = \frac{g}{c_W} m_Z \left[\frac{(1-a_Z)}{2} H Z_\mu Z^\mu + \frac{1}{2m_Z^2} \left\{ \hat{b}_Z H Z_{\mu\nu} Z^{\mu\nu} + \hat{c}_Z H Z_\mu \partial_\nu Z^{\mu\nu} + \tilde{b}_Z H Z_{\mu\nu} \widetilde{Z}^{\mu\nu} \right\} \right], \tag{6}$$

where the \hat{b}_Z and \hat{c}_Z form factors obey $\hat{b}_Z = b_Z - c_Z$ and $\hat{c}_Z = 2c_Z$. In this notation, the form factors h_i^V of Eq. (2) are now given by

$$h_1^V(q^2, p_1^2, p_2^2) = 1 + a_Z - \hat{b}_Z \frac{q^2 - p_1^2 - p_2^2}{m_Z^2} + \frac{\hat{c}_Z}{2} \frac{p_1^2 + p_2^2}{m_Z^2},\tag{7}$$

$$h_2^V(q^2, p_1^2, p_2^2) = \pm 2b_Z, \tag{8}$$

$$h_3^V(q^2, p_1^2, p_2^2) = \pm 2b_Z.$$
 (9)

The main difference between the basis of Lagrangians (1) and (6) is that in the latter the form factor h_2^V is given in terms of only one parameter. Although one can calculate the contributions to each h_i^V in a specific theory, it is not possible to extract the partial contribution from b_Z and c_Z . Furthermore, it turns out that both parametrizations are used indistinctly in the literature, which may be confusing for a cross-check of the numerical results. Thus, to avoid such a situation, we present our results in terms of the parametrization of Lagrangian (6), which is more suited for our work since we can calculate explicitly the h_2^V form factor, out of which the exact SM contribution to the \hat{b}_Z coefficient can be extracted.

Direct bounds on the HZZ anomalous couplings have been obtained using polarization observables of the Z gauge boson produced via the $Z^* \to HZ$ coupling at the LHC at $\sqrt{s} = 14$ TeV [28]. In the basis of Lagrangian (6) such bounds read as

$$\left| \text{Re}[\hat{b}_Z] \right| \leq 3.5 \times 10^{-4}, \quad \left| \text{Im}[\hat{b}_Z] \right| \leq 7.94 \times 10^{-3},$$
 (10)

$$\left|\operatorname{Re}[\widetilde{b}_{Z}]\right| \leqslant 4.76 \times 10^{-3}, \quad \left|\operatorname{Im}[\widetilde{b}_{Z}]\right| \leqslant 6.64 \times 10^{-3}.$$

$$(11)$$

Additional limits on the anomalous HZZ couplings have been obtained from the analysis of several processes at e^+e^- [18, 23], ep [25] and γe colliders [9].

For completeness we now discuss two alternative parametrizations used in the literature for the study of the phenomenology of the HZZ coupling and their mappings with the above parametrizations.

B. The LHC framework

In the analyses of the CMS collaboration [50], the scattering amplitude of the processes mediated by the H^*ZZ coupling is parametrized as follows in the notation of Fig. 1:

$$A(H \to ZZ) \sim \frac{1}{v} \Big[a_1^{ZZ} + \frac{\kappa_1^{ZZ} p_1^2 + \kappa_2^{ZZ} p_2^2}{\left(\Lambda_1^{ZZ}\right)^2} \Big] m_Z^2 \epsilon_1^* \epsilon_2^* + \frac{a_2^{ZZ}}{v} f_{\mu\nu}^{*(1)} f^{*(2)\mu\nu} + \frac{a_3^{ZZ}}{v} f_{\mu\nu}^{*(1)} \widetilde{f}^{*(2)\mu\nu}, \tag{12}$$

where $f^{(i)\mu\nu} = \epsilon_i^{\mu} p_i^{\nu} - \epsilon_i^{\nu} p_i^{\mu}$ and $\tilde{f}^{(i)}_{\mu\nu} = \epsilon_{\mu\nu\rho\sigma} f^{(i)\rho\sigma}$ stand for the field and dual field strength tensors of the Z gauge bosons in momentum space. In the SM $a_1^{ZZ} = 2$ at the tree level. The relations between the coefficients of Eq. (12) and the form factors of the basis discussed above are derived in Appendix A, where we also show that one κ_i form factor is redundant.

Indirect bounds on the a_i^{ZZ} couplings have been obtained by the CMS collaboration [3, 51–53] through effective fractional cross sections f_{ai} , which minimize the uncertainties and are independent of the coupling parametrization. The effective cross-section ratios are defined as

$$f_{ai}^{ZZ} = \frac{|a_i^{ZZ}|^2 \alpha_{ii}^{(2e2\mu)}}{\sum_j |a_j^{ZZ}|^2 \alpha_{jj}^{(2e2\mu)}} \operatorname{sign}\left(\frac{a_i^{ZZ}}{a_1^{ZZ}}\right),\tag{13}$$

where the coefficients $\alpha_{ii}^{(2e2\mu)}$ stand for the cross-sections of $2e + 2\mu$ production via $H \to Z\gamma^*/\gamma^*\gamma^* \to 2e2\mu$ when $a_i^{ZZ} = 1$. The corresponding numerical values, which can be obtained through Monte-Carlo simulation and are normalized with respect to the coefficient $\alpha_{11}^{(2e2\mu)}$, are shown in Table I. In the CMS analysis, the a_i^{ZZ} couplings are considered real, thus their relative phase is 0 or π . The current bounds [3] are shown in Table II.

TABLE I. Anomalous couplings a_i^{ZZ} , cross sections ratios f_{ai}^{ZZ} and coefficients α_{ii}/α_{11} considered in this work. We use the relationship $a_i^{ZZ} = a_i^{WW}$ and the value $\Lambda_1 = m_Z$ for κ_1^{ZZ} . The negative sign arises from the convention adopted in [54] for Eq. (13).

a_i^{ZZ}	f_{ai}^{ZZ}	α_{ii}/α_{11}
a_3^{ZZ}	f_{a3}^{ZZ}	0.153
a_2^{ZZ}	f_{a2}^{ZZ}	0.361
$-k_1^{ZZ}$	$f_{\Lambda 1}^{ZZ}$	1.016

TABLE II. Allowed intervals at 95% C.L. for the coupling parameters f_{ai} obtained by the CMS collaboration [3] through a combined analysis of off-shell and on-shell events. Two scenarios are considered: $\Gamma_H = \Gamma_H^{SM} = 4.1$ MeV and Γ_H unconstrained. The sign of the relative phase between a_i^{ZZ} and a_1^{ZZ} is absorbed into the definition of f_{ai} . [53].

Parameter in units $\times 10^{-5}$	Scenario	Observed at 95% CL
f_{a2}^{ZZ}	$\Gamma_H = \Gamma_H^{SM}$	[-32,514]
$f_{\overline{a2}}$	Γ_H unconstrained	[-38,503]
f_{a3}^{ZZ}	$\Gamma_H = \Gamma_H^{SM}$	[-46,107]
	Γ_H unconstrained	[-46, 110]
cZZ	$\Gamma_H = \Gamma_H^{SM}$	[-11, 46]
$f_{\Lambda_1}^{ZZ}$	Γ_H unconstrained	$[-10,\!47]$

The coupling fractions are also useful to study the limits on the anomalous couplings. They can be obtained from the cross sections ratios of Eq. (13) as

$$\frac{a_i^{ZZ}}{a_j^{ZZ}} = \sqrt{\frac{|f_{ai}^{ZZ}|\alpha_{jj}^{2e2\mu}}{|f_{aj}^{ZZ}|\alpha_{ii}^{2e2\mu}}} \text{sign}\Big(f_{ai}^{ZZ}f_{aj}^{ZZ}\Big).$$
(14)

C. The standard model effective field theory framework

A recent approach well-suited for the analysis of anomalous couplings is offered by the standard model effective field theory (SMEFT). The effective Lagrangian up to dimension six includes 2499 effective operators \mathcal{O}_i [55]

$$\mathcal{L}_{\text{SMEFT}} = \mathcal{L}_{\text{SM}} + \sum_{i}^{2499} C_i \mathcal{O}_i, \tag{15}$$

where the Wilson coefficients C_i along with the SM parameters constitute the parameter space of the SMEFT, whereas the operators \mathcal{O}_i can be described via the Warsaw basis [56], the SILH basis [57] or the Higgs boson basis [58]. These bases are equivalent and their Wilson coefficients can be mapped onto each other. Although the Higgs boson basis is well suited to study the Higgs boson interactions at the LHC, this is not always true: for instance, in this basis the parameter space for diboson production at the LHC is larger than the ones of the other bases.

In the Higgs boson basis [12], the lowest dimension effective Lagrangian for the HZZ interaction can be written, after a redefinition of the couplings, as follows

$$\mathcal{L}_{\text{SMEFT}}^{HZZ} = \frac{H}{\upsilon} \Big[(1 + \delta c_z) \frac{(g_L^2 + g_Y^2) v^2}{4} Z_\mu Z^\mu + c_{zz} \frac{g_L^2 + g_Y^2}{4} Z_{\mu\nu} Z^{\mu\nu} + c_{z\Box} g_L^2 Z_\mu \partial_\nu Z^{\mu\nu} + \widetilde{c}_{zz} \frac{g_L^2 + g_Y^2}{4} Z_{\mu\nu} \widetilde{Z}^{\mu\nu} \Big], \quad (16)$$

where v is the vacuum expectation value (VEV) of the Higgs field, whereas $g_L \equiv g$ and $g_Y \equiv g'$ stand for the $SU(2)_L \times U_Y(1)$ coupling constants. Again, the relations between the form factors of Lagrangians (16) and (6) are presented in Appendix A.

Some remarks concerning the δc_z , c_{zz} , $c_{z\Box}$, and \tilde{c}_{zz} couplings are in order here. Although these couplings are assumed to be real in the SMEFT [59], we will consider a more general scenario where they are complex. Our assumption is motivated by the fact that in some variations of the SMEFT [60, 61] complex Wilson coefficients in the Higgs-gauge sector have been considered, which leads to absorptive parts of the Higgs boson couplings to gauge boson pairs and induce new physics scenarios through CP-violating effects. Such absorptive parts can receive contributions from dimension-8 SMEFT operators, which in some cases could be of the same order of magnitude as the contributions to the real parts arising from dimension-6 operators: for instance, in the case of diboson production via an off-shell Higgs boson at the LHC [62]. Along these lines, complex couplings have also been considered in other EFT analyses, such as in the study of $b \rightarrow s\ell\ell$ transitions [63, 64] and in a possible solution to the apparent R_K and $R_{K^{*0}}$ anomalies [65]. The assumption of complex Higgs boson couplings is of special interest since they can lead to new sources of CP violation in the Higgs sector. Thus, we assume a naive SMEFT with complex Wilson coefficients in the Higgs-gauge sector, which preserves the structure given by the Higgs boson basis but leads to complex HZZ couplings.

For easy reference, we present in Table III the mapping between all the four parametrizations discussed above.

Basis of Eq. (6)	Hagiwara basis	LHC framework	SMEFT
a_Z	a_Z	$a_1^{ZZ} = 2(1 + a_Z)$	$\delta c_z = a_Z$
\hat{b}_Z	$b_Z = \hat{b}_Z + \frac{\hat{c}_Z}{2}$	$a_2^{ZZ} = -2\hat{b}_Z$	$c_{zz} = \frac{4}{g^2 + g'^2} \hat{b}_Z$
\hat{c}_Z	$c_Z = \frac{\hat{c}_Z}{2}$	$\kappa_1^{ZZ} = \hat{c}_Z$	$c_{z\square} = \frac{1}{q_I^2} \hat{c}_Z$
\widetilde{b}_Z	\widetilde{b}_Z	$a_3^{ZZ} = -2\widetilde{b}_Z$	$\widetilde{c}_{zz} = \frac{\frac{3L}{4}}{g^2 + g'^2} \widetilde{b}_Z$

TABLE III. Mappings between form factors for the most popular parametrizations of the HZZ vertex. In our analysis we work in the Basis of Eq. (6).

III. ANALYTICAL RESULTS

We now turn to present our analytical results for the SM one-loop contributions to the HZZ coupling and consider the most general case with off-shell particles, which is known to yield ill-behaved Green's functions that can be gaugedependent and ultraviolet divergent. This issue can be tackled by two approaches: the first one is the so-called pinch technique (PT) [66], which is a diagrammatic approach that allows one to systematically obtain gauge-independent and well-behaved off-shell Green's functions by inserting the off-shell vertex into a physical process and judiciously combining self-energy, vertex, and box diagrams in order to remove the gauge-dependent terms. This approach may turn into a cumbersome task due to the large number of Feynman diagrams involved in the calculation and the use of a general R_{ξ} gauge. Nevertheless, it was shown that, at least up to one-loop level, the well-behaved Green's functions obtained via the PT are identical to those obtained via the background field method (BFM) provided that the Feynman-t'Hooft gauge is used in the calculation [67, 68]. This provides a more economic method to obtain well-behaved off-shell Green's functions as the calculation involves less Feynman diagrams and the corresponding amplitudes can be more easily manipulated in the Feynman-t'Hooft gauge. We thus find it more convenient the use of the BFM to obtain gauge-independent form factors for the HZZ coupling.

For the analytical calculation, we used the Mathematica package FeynArts [69], which allows one to obtain the complete set of Feynman diagrams and their corresponding invariant amplitudes via the BFM. We then used the FeynHelpers and FeynCalc packages [70–72] to perform the tensor decomposition and obtain results in terms of Passarino-Veltman scalar functions, which can be numerically evaluated via either the LoopTools [73] or the Collier [74] packages. The Feynman diagrams that contribute at the one-loop level to the HZZ vertex can be classified into three types according to the particles circulating into the loop: in Fig 2 we show the fermion loop Feynman diagram, whereas the Feynman diagrams with W gauge boson loops (H - Z loops) are shown in Fig. 3 (4). For simplicity, these contributions will be denoted by the subscripts \mathcal{F} , \mathcal{W} , and \mathcal{HZ} , respectively.

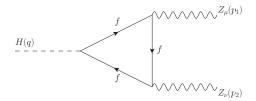

FIG. 2. Feynman diagram for the fermion contribution to the HZZ coupling at the one-loop level.

Since the main aim of this work is the calculation of the SM contributions to the HZZ anomalous couplings, we will focus on the h_2^V form factor and use $a_Z = 0$ throughout the rest of this work. Therefore, following the notation of Ref. [45] our results can be written as

$$h_{2}^{V}(q^{2}, p_{1}^{2}, m_{Z}^{2}) = m_{Z} \frac{g^{2}}{4\pi^{2} c_{W} m_{W}} \Big[\sum_{f} N_{f} m_{f}^{2} \Big\{ g_{Vf}^{2} A_{Vf}^{V}(q^{2}, p_{1}^{2}, m_{Z}^{2}) + g_{Af}^{2} A_{Af}^{V}(q^{2}, p_{1}^{2}, m_{Z}^{2}) \Big\} + A_{W}^{V}(q^{2}, p_{1}^{2}, m_{Z}^{2}) + A_{ZH}^{V}(q^{2}, p_{1}^{2}, m_{Z}^{2}) \Big],$$

$$(17)$$

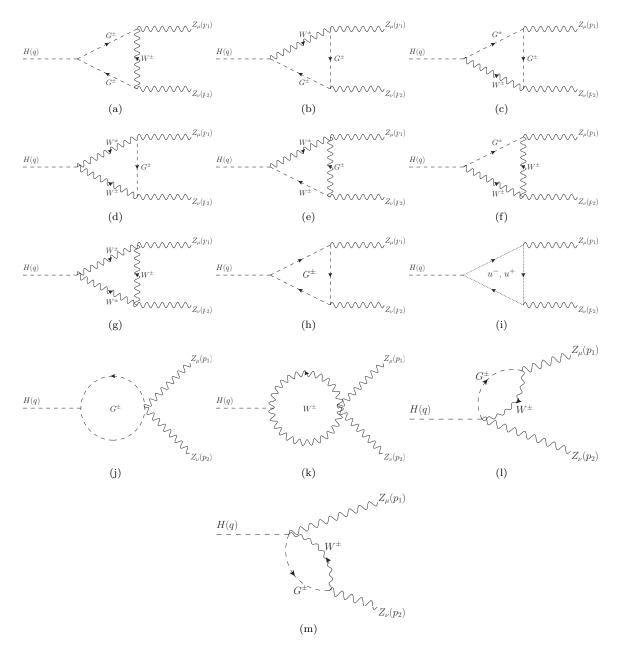

FIG. 3. Feynman diagrams for the contribution of the W gauge boson and its associated unphysical particles at the one-loop level in the Feynman-t'Hooft gauge of the BFM.

where $g_{Vf,Af}$ are the Z gauge boson couplings to fermion pairs:

$$g_{Vf} = \frac{I_f}{2} - Q_f s_W^2, \qquad g_{Af} = \frac{I_f}{2},$$
(18)

with I_f and Q_f the fermion weak isospin and electric charge.

The analytic expressions for the $A_{Vf,Af}^V$, A_W^V and A_{ZH}^V functions in terms of Passarino-Veltman scalar functions are too lengthy and are presented in Appendix B. We present explicit results for the contributions to the H^*ZZ $(p_1^2 = m_Z^2)$ and HZZ^* $(q^2 = m_H^2)$ couplings. We note that for the H^*ZZ coupling, our results agree with those reported in Ref. [45], though there is an apparent change of sign in the coefficients of all the three-point scalar function C_0 , which, however, stems from the fact that there is an extra minus sign in the definition of such functions in [45] as compared to the usual definition presented in Appendix B. We would like to emphasize that, to our knowledge, the results for the HZZ^* $(q^2 = m_H^2)$ coupling have never been reported in the literature. Thus, we present a more comprehensive

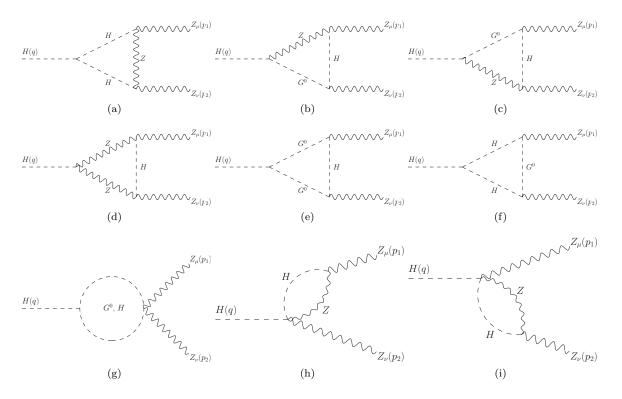

FIG. 4. The same as in Fig. 3 but for the contribution of the Higgs boson and the Z gauge boson and its associated unphysical particle.

calculation, which could be helpful to assess the anomalous contributions to the HZZ coupling in distinct scenarios. The Mathematica code for our analytical results is available for the interested reader in [75], where we also include master formulas for the general case with three off-shell particles, which are too cumbersome to be reported in this work. The results presented in Appendix B can be straightforwardly obtained from such master formulas. It is interesting to note that the three contributions are free of ultraviolet divergences by their own.

IV. BEHAVIOR OF THE HZZ COUPLING

We now turn to present the numerical analysis. For the evaluation of the Passarino-Veltman scalar functions, we used the LoopTools package [73] and a cross-check was done via the Collier routines [74]. A good agreement was found between both numerical evaluations. We will first study the behavior of the H^*ZZ and HZZ^* form factors in an energy region that allows for on-shell final bosons.

A. H^*ZZ form factor

We show in Figs. 5(a) and 5(b) the real and imaginary parts of the fermion (\mathcal{F}) , W gauge boson (\mathcal{W}) , and H-Z boson (\mathcal{HZ}) contributions, along with the total contributions to the H^*ZZ form factor as functions of the Higgs boson transfer momentum ||q||. As for the real part of h_2^H , it is dominated by the \mathcal{W} contribution, whereas the \mathcal{F} and \mathcal{HZ} ones are sizeable at low energy only, where they are of similar order of magnitude than the one of the \mathcal{W} contribution. Furthermore, from ||q|| = 300 GeV onwards, the \mathcal{F} and \mathcal{HZ} contributions are of similar size but of opposite sign and tend to cancel each other out. It is also interesting to note that the fermion contribution is mainly dominated by the top quark, whereas all other fermions yield negligible contributions. As far as the imaginary part of the h_2^H form factor is concerned, we observe that the \mathcal{W} contribution is also the dominant one, whereas the \mathcal{F} and \mathcal{HZ} contributions are one order of magnitude smaller. As expected, the absorptive part of the \mathcal{F} contribution is non-vanishing only above the threshold $||q|| = 2m_t$, where the two top quarks attached to the off-shell Higgs boson can be on-shell. In general, the real and imaginary parts of h_2^H are of similar order of magnitude, about $10^{-2} - 10^{-3}$,

9

but at high energies the absorptive part can be larger than the real part. This behavior was also observed in other off-shell form factors: see for instance [38–42].

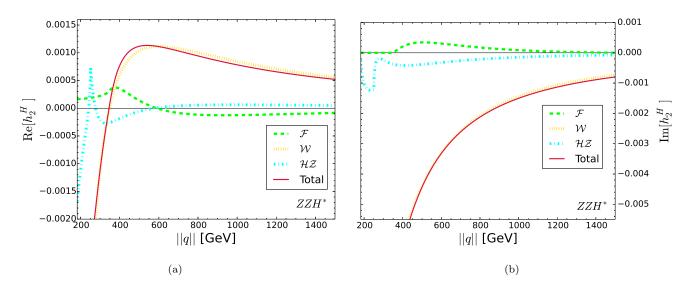

FIG. 5. One-loop contributions to the real (left plot) and absorptive (right plot) parts of the form factor h_2^H as functions of the Higgs boson transfer momentum ||q||: fermion (\mathcal{F}) , W gauge boson (\mathcal{W}) , H-Z bosons (\mathcal{HZ}) and total contributions.

For illustration purposes, the values of the real and imaginary parts of the h_2^H form factors at a few ||q|| values are presented in Table IV, along with the values for \hat{b}_z , a_2^{ZZ} and c_{zz} , which can be obtained from Eqs. (8), (A2) and (A15), respectively. In effective field theories, the couplings are taken as constant and do not depend on ||q||, but our results can be useful to constrain the energy scale Λ of the model.

TABLE IV. Total contributions to the h_2^H form factor for a few values of ||q||. The respective values of \hat{b}_Z , a_2^{ZZ} and c_{zz} are also shown. All these results are in units of 10^{-3} .

B. HZZ^* form factor

We now show in Fig. 6 the behavior of the real and imaginary parts of the partial and total contributions to the HZZ^* form factor as functions of the off-shell Z gauge boson transfer momentum $||p_1||$. We observe that the h_2^Z form factor has a similar behavior to that of h_2^H . In both cases the \mathcal{W} contribution dominates, but at low energies, the \mathcal{F} and \mathcal{HZ} contributions may be of similar order of magnitude than the \mathcal{W} contribution, whereas at high energies they are negligible.

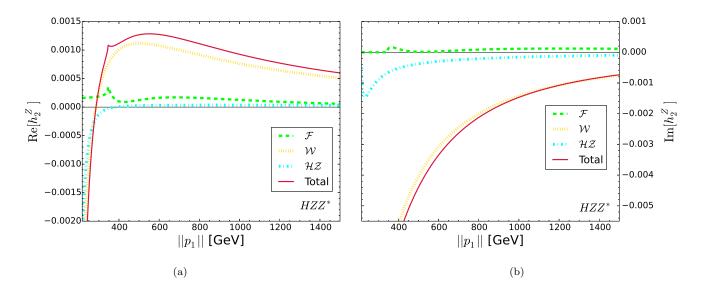

FIG. 6. The same as in Fig. 5, but for the form factor h_2^Z as a function of off-shell Z gauge boson transfer momentum $||p_1||$.

In Table V, we present numerical values for the real and absorptive parts of h_2^Z at a few values of $||p_1||$. We also present the respective values for \hat{b}_Z , a_2^{ZZ} and c_{zz} . We can observe that at some energy values, the h_2^Z form factor is larger than the h_2^H one, reaching values of the order of $10^{-2} - 10^{-3}$. It is also noted that for both H^*ZZ and HZZ^* couplings, the real and absorptive parts of the anomalous coupling \hat{b}_Z are of the order of $10^{-3} - 10^{-4}$, which agrees with [28]. On the experimental side, the current bounds on \hat{b}_Z are of the same order of magnitude, and thus this anomalous coupling could be at reach of the LHC in the near future.

$ p_1 $	h_2^Z	\hat{b}_Z	a_2^{ZZ}	C_{ZZ}

TABLE V. The same as in Table IV, but for the form factor h_2^Z for as a function of $||p_1||$.

V. BOUNDS ON THE H*ZZ ANOMALOUS COUPLINGS

Until now we have not focused on the \hat{c}_Z and \tilde{b}_Z anomalous couplings yet. Limits on their real and absorptive parts have been set in the past [28], though their energy dependence has not been considered. Also, the current CMS bounds [3] only consider constraints on the ratios of such couplings, which cannot be used to assess the corresponding contributions to physical observables [28]. These couplings are expected to play a relevant role in LHC processes given the recent measurement of the $H^* \to ZZ$ process, therefore, independent constraints on each one of these anomalous couplings are necessary and we will address this issue below.

A. Bounds from LHC data

By combining the LHC bounds on the effective ratios f_{ai} of Table II through their definitions of Eq. (14) [3], it is possible to obtain limits on the ratios a_i^{ZZ}/a_2^{ZZ} , which are presented in Table VI, where we only consider the scenario with $\Gamma_H = \Gamma_H^{SM}$ (the bounds obtained in the unconstrained case are of a similar order of magnitude). In Table VI we also present the bounds in terms of the \hat{b}_Z , \hat{c}_Z and \tilde{b}_Z form factors, which can be easily obtained via the mappings of Table III. In the following, we will use the parametrization of Eq. (6), but our bounds can be easily translated into the remaining parametrizations discussed in Sec. II.

TABLE VI. Allowed intervals at 95 % CL for the ratios defined in Eq. (14), where we consider the case $\Gamma_H = \Gamma_H^{SM}$ and the limits of Table II.

Ratio	Allowed values
$\overline{a_3^{ZZ}/a_2^{ZZ}}$	[-1.84, 0.70]
κ_1^{ZZ}/a_2^{ZZ}	$\left[-0.35,0.18\right]$
$\widetilde{b}_Z/\hat{b}_Z$	[-1.84, 0.70]
\hat{c}_Z/\hat{b}_Z	$\left[-0.36, 0.70 ight]$

We now use the constraints of Table VI and the expressions for \hat{b}_Z from Sec. III to find the allowed areas of the real parts of \tilde{b}_Z and \hat{c}_Z as functions of the Higgs boson transfer momentum. Furthermore, since the results of Table IV hint that the real and absorptive parts of the H^*ZZ form factors are of similar size, we will assume that the limits of Table VI are also valid for the imaginary parts of \tilde{b}_Z and \hat{c}_Z , which allows us to set constraints on $\text{Im}[\tilde{b}_Z]$ and $\text{Im}[\hat{c}_Z]$. For our calculations, we use the expressions of the form factor $h_2^H = 2\hat{b}_Z$, but the same results are expected for h_2^Z . Moreover, only energy regions where both Z gauge bosons can be on-shell are considered in our analysis.

Our results for the allowed area on the ||q|| vs $\operatorname{Re}[\tilde{b}_Z]$ plane are shown in Fig. 7(a). It is observed that for a fixed small value of ||q||, the allowed $\operatorname{Re}[\tilde{b}_Z]$ values lie in the $[-10^{-3}, 10^{-2}]$ interval, which becomes narrower as ||q|| increases: at high ||q||, $\operatorname{Re}[\tilde{b}_Z]$ is allowed to have values of the order of 10^{-4} . It is also worth noting that around ||q|| = 320 GeV, the allowed $\operatorname{Re}[\tilde{b}_Z]$ area collapses, which stems from the fact that in such a region the real part of \hat{b}_Z changes sign and $\operatorname{Re}[\hat{b}_Z] \approx 0$ [see Fig. 5(a)]. Therefore, very small values of $\operatorname{Re}[\tilde{b}_Z]$ are required to get \tilde{b}_Z/\hat{b}_Z inside the allowed region. As for $\operatorname{Im}[\tilde{b}_Z]$, the corresponding limits are shown in Fig. 7(b), where we observe that for small ||q|| there is a relatively large allowed area, which becomes smaller as ||q|| increases, with the allowed $\operatorname{Im}[\tilde{b}_Z]$ values being of the order of $10^{-2} - 10^{-3}$. In this case, there is no abrupt collapse of the allowed area as the absorptive part of \tilde{b}_Z does not change the sign in this energy range. The current bounds on the real and absorptive parts of \tilde{b}_Z are of the order of 10^{-3} [28], therefore our limits obtained for high energies are more stringent.

We now show the allowed areas of the real and absorptive parts of \hat{c}_Z as functions of ||q|| in Figs. 8(a) and 8(b), respectively. The results are similar to those obtained for \tilde{b}_Z . Nevertheless, in this case, the allowed upper values of both the real and imaginary parts of \hat{c}_Z are of the order of 10^{-3} at low energies, which is one order of magnitude smaller than previous results [18], and become smaller as the energy increases. It is noted that in general, the constraints on the *CP* violating form factor \tilde{b}_Z are less tight than those on the *CP* conserving one \hat{c}_Z , although both can be of the same order of magnitude in some energy regions.

As already mentioned, our constraints on \tilde{b}_Z and \hat{c}_Z can be translated into other parametrizations via the mappings of Table III. Therefore, we can easily obtain the allowed regions for the couplings a_3^{ZZ} , κ_1^{ZZ} , \tilde{c}_{zz} and $c_{z\Box}$, which are used in other analyses of the HZZ vertex. For instance, in the SMEFT the anomalous couplings do not depend on the off-shell boson transfer momenta [76], and the scale Λ , where the effective model remains valid, has been absorbed in the definition of the Wilson coefficients \tilde{c}_{zz} and $c_{z\Box}$. Hence, our results may be used to set a bound on Λ . The corresponding limits are presented in Tables VII and VIII. We find that the allowed values of the real and imaginary parts of the CP violating form factors a_3^{ZZ} and \tilde{c}_{zz} are in general of the order of $10^3 - 10^{-4}$, but they can be as large as 10^{-2} for some ||q|| values. On the other hand, the bounds on the CP conserving form factors k_1^{ZZ} have similar behavior to the ones obtained for \hat{c}_Z , and the allowed values of this form factor can be as large as 10^{-3} at most, whereas the SMEFT coefficient $c_{z\Box}$ can be in general of the order of $10^{-3} - 10^{-4}$. All these values decrease at high energies.

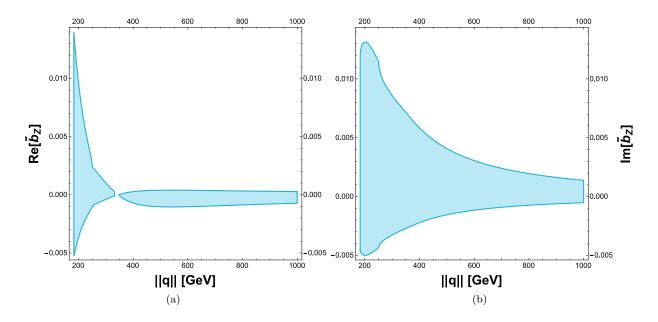

FIG. 7. Allowed area at 95% CL for the the real (left plot) and absorptive (right plot) parts of \tilde{b}_Z as functions of ||q||. These results are compatible with the bounds of Table VI.

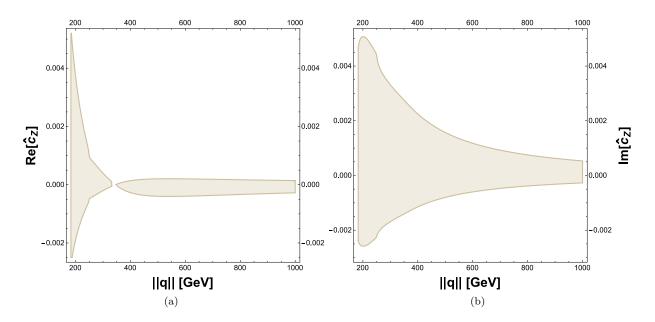

FIG. 8. The same as in Fig. 7, but for the \hat{c}_Z form factor.

TABLE VII. Allowed intervals of the real and absorptive parts of the CP violating form factor of the H^*ZZ coupling for a few values of the transfer momentum. We consider the parametrizations of Eq. (6) (\tilde{b}_Z) , the LHC framework (a_3^{ZZ}) and the SMEFT (\tilde{c}_{zz}) .

$\ q\ $	$\operatorname{Re}[\tilde{b}_Z]$	$\operatorname{Re}\left[a_{3}^{ZZ}\right]$	$\operatorname{Re}\left[\widetilde{c}_{zz}\right]$	$\operatorname{Im}[\tilde{b}_Z]$	$\operatorname{Im}\left[a_{3}^{ZZ}\right]$	$\operatorname{Im}[\tilde{c}_{zz}]$

B. Bounds from weak dipole moments

CP violating effects can be severely constrained by limits on the electric dipole moments of the electron and neutron. Nevertheless, the HZZ coupling does not contribute to these observable quantities, which can be induced, for instance, by anomalous contributions to the $H\gamma\gamma$ and $HZ\gamma$ couplings [77–79]. On the other hand, the HZZvertex does contribute to the weak magnetic and weak electric dipole moments (WMDM and WEDM) of fermions, which are determined by the anomalous contributions to the $Zf\bar{f}$ vertex function [80]

$$\Gamma^{\mu} \subset ie \left(i\sigma^{\mu\nu} p_{\nu} F_2(p^2) + F_3(p^2) \sigma^{\mu\nu} p_{\nu} \gamma^5 \right), \tag{19}$$

with the WMDM and WEDM being given by $a_f^W = -2m_f F_2(m_Z^2)$ and $d_f^W = -eF_3(m_Z^2)$. The latter is *CP* violating and can be induced up to the three-loop level in the SM.

In the SM, the HZZ coupling contributes at the one-loop level to the WMDM of fermions via the Feynman diagrams of Fig. 9, which have already been calculated [81, 82]. The corresponding contribution from those diagrams to the WEDM via CP-violating contributions to the $Hf\bar{f}$ vertex have also been calculated in the minimal supersymmetric standard model (MSSM) [83] and models with an extended scalar sector [82]. However, the contribution of the anomalous HZZ CP-violating form factor has not been studied yet to our knowledge.

We can obtain a rough estimate for the contribution to the WEDM from the interaction Lagrangian of Eq. (6):

$$d_f^W \simeq \frac{e\alpha}{4\pi s_W^3 c_W} \frac{m_f}{m_Z^2} \operatorname{Im}\left(\tilde{b}_Z\right) I\left(\frac{m_\tau^2}{m_Z^2}, \frac{m_H^2}{m_Z^2}\right),\tag{20}$$

where I(x, y) is the loop integral function, which we will assume to be of the order of O(1). For the tau lepton we obtain

$$d_{\tau}^{W} \approx \operatorname{Im}\left(\widetilde{b}_{Z}\right) \times 10^{-20} \quad \text{e-cm},$$
(21)

which is well beyond the current best limit of $d_{\tau}^W < 10^{-18}$ e-cm for both the real and imaginary parts [84]. Therefore, our bounds on \tilde{b}_Z presented in Table VII are not in conflict with the WEDM of the tau lepton.

The *CP*-violating effects induced by the HZZ couplings have not been studied profusely, thus there are no tight bounds on the h_3^V form factor currently.

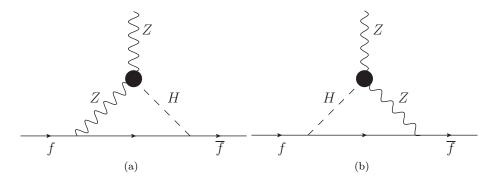

FIG. 9. Feynman diagrams for the contribution of the anomalous HZZ coupling to the fermion weak dipole moments.

VI. ZZ PRODUCTION VIA THE H^*ZZ COUPLING

We now study the effects of the anomalous HZZ couplings on the partial decay width of the $H^* \rightarrow ZZ$ process. The virtuality of the Higgs boson in physical observables such as cross-sections and partial decay widths have been established in Ref. [85], though the implications of an absorptive part of the HZZ coupling on such observables have not been discussed in the literature yet. To study their role in ZZ production, we consider complex HZZ anomalous couplings and express the h_i^H form factors as

$$h_i^H = \operatorname{Re}[h_i^H] + i \operatorname{Im}[h_i^H], \qquad (22)$$

which lead to the following invariant amplitude for the production of two on-shell Z gauge bosons from an off-shell Higgs boson:

$$\mathcal{M}(\lambda_1, \lambda_2) = \frac{g}{c_W} m_Z \left\{ g^{\mu\nu} \left(\operatorname{Re}[h_1^H] + i \operatorname{Im}[h_1^H] \right) + \frac{p_2^{\mu} p_1^{\nu}}{m_Z^2} \left(\operatorname{Re}[h_2^H] + i \operatorname{Im}[h_2^H] \right) \right. \\ \left. + \frac{\epsilon^{\mu\nu\alpha\beta} p_{1\alpha} p_{2\beta}}{m_Z^2} \left(\operatorname{Re}[h_3^H] + i \operatorname{Im}[h_3^H] \right) \right\} \epsilon^*_{\mu}(p_1, \lambda_1) \epsilon^*_{\nu}(p_2, \lambda_2),$$

$$(23)$$

where λ_i and $\epsilon_{\mu}(p_i, \lambda_i)$ (i = 1, 2) stand for the polarization and polarization vector of the Z gauge bosons. We would like to stress that the absorptive parts $\text{Im}[h_k^H]$ (k = 1, 2, 3) have not been considered in previous studies of the $H^* \to ZZ$ process [34, 45].

A. The unpolarized case

From the amplitude (23), the following partial decay width can be obtained:

$$\Gamma_{H^* \to ZZ} = \frac{g^2 \sqrt{q^2 - 4m_Z^2}}{512\pi q^2 c_W^2 m_Z^6} \Big\{ 4q^6 m_Z^2 \Big(\left(\operatorname{Im}[h_1^H] - 2\operatorname{Im}[h_2^H] \right) \operatorname{Im}[h_2^H] + \left(\operatorname{Re}[h_1^H] - 2\operatorname{Re}[h_2^H] \right) \operatorname{Re}[h_2^H] \Big) \\ + 4q^4 m_Z^4 \Big(2 \left(2\operatorname{Im}[h_2^H]^2 + \operatorname{Im}[h_3^H]^2 + 2\operatorname{Re}[h_2^H]^2 + \operatorname{Re}[h_3^H]^2 \right) + \operatorname{Im}[h_1^H]^2 - 6\operatorname{Im}[h_2^H] \operatorname{Im}[h_1^H] \\ + \operatorname{Re}[h_1^H]^2 - 6\operatorname{Re}[h_1^H] \operatorname{Re}[h_2^H] \Big) - 16q^2 m_Z^6 \Big(2 \left(\operatorname{Im}[h_3^H]^2 + \operatorname{Re}[h_3^H]^2 \right) + \operatorname{Im}[h_1^H]^2 - 2\operatorname{Im}[h_2^H] \operatorname{Im}[h_1^H] \\ + \operatorname{Re}[h_1^H]^2 - 2\operatorname{Re}[h_1^H] \operatorname{Re}[h_2^H] \Big) + 48m_Z^8 \left(\operatorname{Im}[h_1^H]^2 + \operatorname{Re}[h_1^H]^2 \right) + q^8 \left(\operatorname{Im}[h_2^H]^2 + \operatorname{Re}[h_2^H]^2 \right) \Big\}, \quad (24)$$

which reduces to the SM tree-level result [45] when $\operatorname{Re}[h_1^H] = 1$, $\operatorname{Re}[h_{2,3}^H] = \operatorname{Im}[h_{1,2,3}^H] = 0$:

$$\Gamma_{H^* \to ZZ}^{\text{Tree}} = \frac{g^2 \sqrt{q^2 - 4m_Z^2}}{512\pi c_W^2 m_Z^6} \left(4q^2 m_Z^4 - 16m_Z^6 + 48\frac{m_Z^8}{q^2} \right).$$
(25)

The SM contributions to the $H^* \to ZZ$ decay was studied long ago up to the one-loop level [34, 45], but the entire set of anomalous couplings has not been considered yet and their implications remain unexplored. Thus, a complete analysis is required since any non-standard contribution to the anomalous HZZ couplings may be at the reach of measurement in a near future. To examine the corresponding effects on Z pair production, we define the ratio \mathcal{R} between the full (tree-level SM plus one-loop SM plus non-standard anomalous contributions) and the SM tree-level partial decay widths

$$\mathcal{R} = \frac{\Gamma_{H^* \to ZZ}}{\Gamma_{H^* \to ZZ}^{\text{Tree}}}.$$
(26)

For the numerical evaluation of Eq. (26) we write the h_i^H form factors in terms of the \hat{b}_Z , \hat{c}_Z and \tilde{b}_Z anomalous couplings via Eqs. (7), (8), (9). Furthermore, for \hat{b}_Z we use the SM one-loop results obtained in Sec. III, whereas for the remaining anomalous couplings we use values consistent with the bounds of Tables VII and VIII. To asses the effects of such anomalous couplings, we consider in our analysis the following illustrative scenarios:

- Scenario I: $\operatorname{Re}[\hat{c}_Z] \sim \operatorname{Re}[\tilde{b}_Z] = 10^{-4} \text{ and } \operatorname{Im}[\hat{c}_Z] = \operatorname{Im}[\tilde{b}_Z] = 10^{-3}.$
- Scenario II: $\operatorname{Re}[\hat{c}_Z] = \operatorname{Re}[\tilde{b}_Z] \sim -10^{-3}$ and $\operatorname{Im}[\hat{c}_Z] = \operatorname{Im}[\tilde{b}_Z] \sim 10^{-3}$.
- Scenario III: $-\operatorname{Im}[\tilde{b}_Z] = \operatorname{Re}[\hat{c}_Z] = 10^{-3} \text{ and } -\operatorname{Im}[\hat{c}_Z] = \operatorname{Re}[\tilde{b}_Z] \sim 10^{-4}.$

We now show in Fig. 10 the behavior of \mathcal{R} as a function of the Higgs boson transfer momentum ||q|| for the tree-level plus one-loop level SM contribution, namely, $\hat{c}_Z = \tilde{b}_Z = 0$, and also in the three above scenarios. We observe that at high energies \mathcal{R} becomes constant: the curves for the one-loop SM contribution and that for scenario II approaches the unity, whereas the curves for scenarios I and III show a slight deviation up to about 0.2%. On the other hand, at low energies, the deviation of \mathcal{R} from the unity can be as large as 3% in the four scenarios, which could put the anomalous couplings at the reach of measurement. Nevertheless, discriminating between the SM one-loop contribution and those arising from the \hat{c}_Z and \tilde{b}_Z anomalous couplings could represent a hard task.

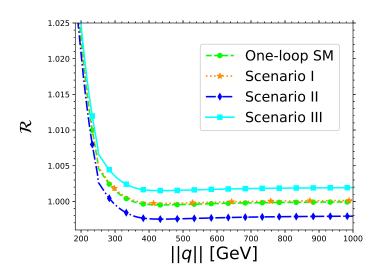

FIG. 10. Behavior of the ratio \mathcal{R} as function of the transfer momentum of the Higgs boson ||q|| for the SM contribution up to one-loop leval, namely, $\hat{c}_Z = \tilde{b}_Z = 0$, and also in the three scenarios discussed in the text for \hat{c}_Z and \tilde{b}_Z . For \hat{b}_Z we use the expressions obtained in Sec. III.

B. The polarized case

From the amplitude (23) it is also possible to obtain the partial decay width $\Gamma_{H^* \to ZZ}$ for polarized Z gauge bosons. In the frame in which the vector bosons propagate along the x - z plane, the polarization vectors can be written as

$$\epsilon_{1,2}^{\mu}(0) = \frac{1}{m_Z} \Big(\|\vec{p}\|, \pm E \sin \theta, 0, \pm E \cos \theta \Big),$$

$$\epsilon_1^{\mu}(L/R) = \frac{1}{\sqrt{2}} \Big(0, \pm \cos \theta, -i, \mp \sin \theta \Big),$$
(27)

where the energy and magnitude of the three-momentum can be written as $E = \sqrt{q^2/2}$ and $||p|| = \sqrt{q^2 - 4m_Z^2/2}$. In terms of the three contributing polarized amplitudes $\mathcal{M}(0,0)$, $\mathcal{M}(L,L)$, $\mathcal{M}(R,R)$ the squared amplitude is

$$\mathcal{M}^{2} = \left(\frac{g}{c_{W}}\right)^{2} m_{Z}^{2} \sum_{\lambda_{i}} \left(\mathcal{M}^{2}(\lambda_{i},\lambda_{i})\right)$$
$$= \left(\frac{g}{c_{W}}\right)^{2} m_{Z}^{2} \left(\mathcal{M}_{LL}^{2} + \mathcal{M}_{RR}^{2} + \mathcal{M}_{00}^{2}\right), \tag{28}$$

with $\mathcal{M}^2(\lambda_i, \lambda_i) \equiv \mathcal{M}^2_{\lambda_i, \lambda_i}$ given by

$$\mathcal{M}_{LL}^{2} = \frac{1}{4m_{Z}^{4}} \Big\{ 4m_{Z}^{2} \sqrt{q^{4} - 4q^{2}m_{Z}^{2}} \Big(\operatorname{Re}[h_{1}^{H}]\operatorname{Im}[h_{3}^{H}] - \operatorname{Im}[h_{1}^{H}]\operatorname{Re}[h_{3}^{H}] \Big) \\ + q^{2} \left(q^{2} - 4m_{Z}^{2} \right) \left(\operatorname{Re}[h_{3}^{H}]^{2} + \operatorname{Im}[h_{3}^{H}]^{2} \right) + 4m_{Z}^{4} \Big(\operatorname{Re}[h_{1}^{H}]^{2} + \operatorname{Im}[h_{1}^{H}]^{2} \Big) \Big\},$$
(29)

$$\mathcal{M}_{RR}^{2} = \frac{1}{4m_{Z}^{4}} \Big\{ 4m_{Z}^{2} \sqrt{q^{4} - 4q^{2}m_{Z}^{2}} \Big(-\operatorname{Re}[h_{1}^{H}]\operatorname{Im}[h_{3}^{H}] + \operatorname{Im}[h_{1}^{H}]\operatorname{Re}[h_{3}^{H}] \Big) \\ + q^{2} \left(q^{2} - 4m_{Z}^{2}\right) \left(\operatorname{Re}[h_{3}^{H}]^{2} + \operatorname{Im}[h_{3}^{H}]^{2}\right) + 4m_{Z}^{4} \left(\operatorname{Re}[h_{1}^{H}]^{2} + \operatorname{Im}[h_{1}^{H}]^{2}\right) \Big\},$$
(30)

and

J

$$\mathcal{M}_{00}^{2} = \frac{1}{16m_{Z}^{8}} \Big\{ 4q^{6}m_{Z}^{2} \Big[\left(\mathrm{Im}[h_{1}^{H}] - 2\mathrm{Im}[h_{2}^{H}] \right) \mathrm{Im}[h_{2}^{H}] + \left(\mathrm{Re}[h_{1}^{H}] - 2\mathrm{Re}[h_{2}^{H}] \right) \mathrm{Re}[h_{2}^{H}] \Big] \\ + 4q^{4}m_{Z}^{4} \Big[4 \left(\mathrm{Im}[h_{2}^{H}]^{2} + \mathrm{Re}[h_{2}^{H}]^{2} \right) + \mathrm{Im}[h_{1}^{H}]^{2} - 6\mathrm{Im}[h_{2}^{H}] \mathrm{Im}[h_{1}^{H}] + \mathrm{Re}[h_{1}^{H}]^{2} - 6\mathrm{Re}[h_{1}^{H}] \mathrm{Re}[h_{2}^{H}] \Big] \\ - 16q^{2}m_{Z}^{6} \Big[\mathrm{Im}[h_{1}^{H}]^{2} - 2\mathrm{Im}[h_{2}^{H}] \mathrm{Im}[h_{1}^{H}] + \mathrm{Re}[h_{1}^{H}] \left(\mathrm{Re}[h_{1}^{H}] - 2\mathrm{Re}[h_{2}^{H}] \right) \Big] \\ + 16m_{Z}^{8} \left(\mathrm{Im}[h_{1}^{H}]^{2} + \mathrm{Re}[h_{1}^{H}]^{2} \right) + q^{8} \left(\mathrm{Im}[h_{2}^{H}]^{2} + \mathrm{Re}[h_{2}^{H}]^{2} \right) \Big\},$$

$$(31)$$

which agree with the results of Ref. [7] in the case of real form factors, though there is a difference of sign in $\mathcal{M}(0,0)$, which in our case is absorbed in the corresponding polarization vector.

The polarized partial width can be defined as

$$\Gamma_{H^* \to Z_{\lambda_i} Z_{\lambda_i}} = \frac{g^2 m_Z^2 \sqrt{q^2 - 4m_Z^2}}{32\pi q^2 c_W^2} \mathcal{M}_{\lambda_i \lambda_i}^2.$$
(32)

We note that the *CP*-violating form factor h_3^H only enters into \mathcal{M}_{LL}^2 and \mathcal{M}_{RR}^2 , which only differ by a change of sign of h_3^H . This peculiarity allows us to introduce an asymmetry, which, to our knowledge, has never been reported in the literature. This left-right asymmetry can be written as

$$\mathcal{A}_{LR} = \frac{\Gamma_{H^* \to Z_L Z_L} - \Gamma_{H^* \to Z_R Z_R}}{\Gamma_{H^* \to Z_L Z_L} + \Gamma_{H^* \to Z_R Z_R}},\tag{33}$$

and can be expressed in terms of the real and imaginary parts of the form factors via Eqs. (29) and (30):

$$\mathcal{A}_{LR} = \frac{4m_Z^2 \|q\| \sqrt{q^2 - 4m_Z^2} \left(\operatorname{Re}[h_1^H] \operatorname{Im}[h_3^H] - \operatorname{Re}[h_3^H] \operatorname{Im}[h_1^H] \right)}{q^2 \left(q^2 - 4m_Z^2 \right) \left(\operatorname{Re}[h_3^H]^2 + \operatorname{Im}[h_3^H]^2 \right) + 4m_Z^4 \left(\operatorname{Im}[h_1^H]^2 + \operatorname{Re}[h_1^H]^2 \right)}.$$
(34)

It is worth noting that the size of this asymmetry is dominated by the CP-violating form factor h_3^H as \mathcal{A}_{LR} is proportional to its real and absorptive parts. Therefore, CP-violating effects can be explored via polarized Z gauge bosons through the $H^* \to ZZ$ process. Also, from Eq. (34) we observe that a non-vanishing \mathcal{A}_{LR} requires the presence of absorptive parts of both h_1^H and h_3^H , which are only induced for an off-shell Higgs boson. In summary, the left-right asymmetry is a consequence of the presence of CP violation and complex form factors. Other asymmetries have been studied in the past through the HZZ couplings [22, 49], though they are of different nature as are given in terms of the energy of the four-lepton final state. Our result stress the relevance of the absorptive parts of the anomalous couplings in processes where off-shell particles are involved, though such terms have been overlooked in the past despite they could yield sizeable deviations in several observables.

In the SM, the \mathcal{A}_{LR} asymmetry would vanish up to the two-loop level as the *CP*-violating form factor h_3^H has been estimated to arise up to the three-loop level, with a value of the order of 10^{-11} [49]. Therefore, if we take $\operatorname{Re}[h_3^H] = \operatorname{Im}[h_3^H] \approx 10^{-11}$ and use the SM contributions to the *CP* conserving form factors including only one-loop corrections, i.e., $\hat{c}_Z = 0$, we obtain the following estimate

$$\mathcal{A}_{LR}^{SM} \approx 10^{-8} - 10^{-9},\tag{35}$$

for energies up to ||q|| = 3000 GeV.

To assess the importance of the *CP*-violating form factor, together with the complete anomalous couplings contributions and their allowed values obtained in Sec. V, we fix $\operatorname{Re}[\hat{c}_Z] = \operatorname{Im}[\hat{c}_Z] = 10^{-3}$ and consider the following four scenarios:

- Scenario i: $\operatorname{Re}[\widetilde{b}_Z] = 10^{-3}$ and $\operatorname{Im}[\widetilde{b}_Z] = 10^{-2}$.
- Scenario ii: $\operatorname{Re}[\widetilde{b}_Z] = 10^{-3}$ and $\operatorname{Im}[\widetilde{b}_Z] = -10^{-2}$.
- Scenario iii: $\operatorname{Re}[\widetilde{b}_Z] = 10^{-4}$ and $\operatorname{Im}[\widetilde{b}_Z] = 10^{-3}$.
- Scenario iv: $\operatorname{Re}[\widetilde{b}_Z] = \operatorname{Im}[\widetilde{b}_Z] = 10^{-4}$.

We show in Fig. 11 the behavior of the \mathcal{A}_{LR} asymmetry as a function of the Higgs boson transfer momentum ||q|| in such scenarios. We first consider scenarios i and ii, where the real and imaginary parts of the CP-violating form factor h_3^H are larger than $\operatorname{Re}[\hat{c}_Z]$ and $\operatorname{Im}[\hat{c}_Z]$. We observe that, except for a change of sign, \mathcal{A}_{LR} shows a similar behavior and can reach values of the order of O(1), which means that the difference between the production of left-handed and right-handed Z gauge bosons can be as large as the production of transverse Z gauge bosons. Thus, if we only consider the total Z gauge boson production, a lot of information about the properties of Z_L and Z_R is lost as the terms responsible for the asymmetry are cancelled out. As far as scenarios iii and iv are concerned, \mathcal{A}_{LR} can reach values of the order of 10^{-3} and 10^{-4} , respectively, at low energies, which are still much larger, by about four orders of magnitude, than the SM contribution. In general, we note that in the four scenarios \mathcal{A}_{LR} is smaller at low energies and reaches its highest values at high energy. This behavior is contrary to that observed for the total Z gauge bosons pair production of Fig. 10, where the anomalous coupling effects can only be observed in the region of low energy. Therefore, the study of polarized Z gauge bosons offers a good opportunity to detect non-SM contributions to the HZZ vertex, since the energy region where such effects can be discriminated is broader than for the production of unpolarized Z gauge bosons in the $H \to ZZ^* \to 4\ell$ process has already been explored under the context of the SM and new physics scenarios [86, 87].

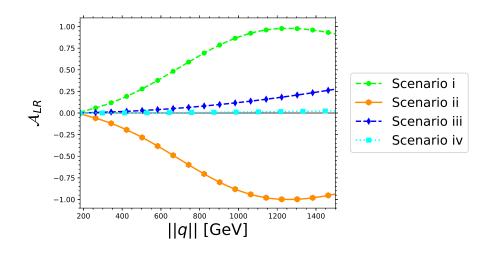

FIG. 11. \mathcal{A}_{LR} asymmetry as a function of the transfer momentum of the Higgs boson ||q|| for the four scenarios described in the text for the real and absorptive parts of the anomalous couplings \hat{c}_Z and \tilde{b}_Z . For \hat{b}_Z we use the one-loop SM results presented in Sec. III.

For completeness, we show in Fig. 12 the behavior of the partial decay widths $\Gamma_{H^* \to Z_L Z_L, Z_R Z_R}$ as functions of ||q|| in the same scenarios of Fig. 11 except for scenario iv, which does not yield interesting results. We also include the tree and one-loop level SM results. Again, the anomalous coupling contributions become more significant as the energy increases, which stems from the fact that large deviations from the SM results arising from the *CP*-violating form factor (scenarios i and ii) are larger at very high energies. This can be explained if we analyze the high energy behavior of Eq. (32), which for transverse polarizations reads as

$$\Gamma_{H^* \to Z_L Z_L / Z_R Z_R} = \frac{g^2 \|q\|}{128\pi c_W^2 m_Z^2} \Big\{ \pm 4m_Z^2 \Big(\operatorname{Re}[h_1^H] \operatorname{Im}[h_3^H] - \operatorname{Im}[h_1^H] \operatorname{Re}[h_3^H] \Big) + q^2 \Big(\operatorname{Re}[h_3^H]^2 + \operatorname{Im}[h_3^H]^2 \Big) \Big\}, \quad (36)$$

where the term related to \mathcal{A}_{LR} in Eq. (34) can be recognized, ensuring a non-zero asymmetry at very high energies. In this regime, the main contributions arise from the h_3^H quadratic terms. Thus, as observed in Fig. 12, the *CP* violating form factor is the main responsible for the deviations from the SM predictions since they are more relevant in the $q^2 \to \infty$ limit.

In summary, the window to detect effects of anomalous couplings, in particular of the CP-violating one, increases for high energy polarized Z gauge bosons. Therefore, the recent measurement of the production of two Z gauge bosons from an off-shell Higgs boson hints the possibility of detecting anomalous HZZ couplings in the near future with the advent of LHC upgrades. Moreover, the implications of these contributions could also be observed via the four-lepton final state $H^* \to ZZ \to 4\ell$ [87], where any deviation from the SM would be a clear evidence of new physics. To our knowledge, only the case $H \to ZZ^* \to 4\ell$ has been explored up to now [7, 49, 50, 86–90], thus we expect that our calculation could be helpful for new lines of research. We also would like to point out that we refrain from presenting the study of pair-production of longitudinally polarized Z gauge bosons as it yields no significant deviation from the SM.

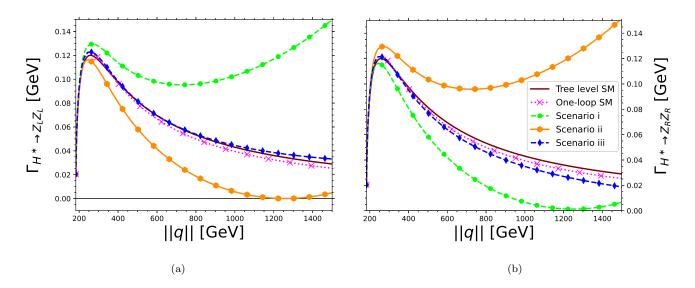

FIG. 12. Partial decay widths of the processes $H^* \to Z_L Z_L / Z_R Z_R$ as functions of the Higgs boson transfer momentum ||q|| in the first three scenarios of Fig. 11 along with the tree and one-loop level SM predictions.

VII. CONCLUSIONS AND OUTLOOK

Motivated by the recent measurement of Z gauge boson pair production from an off-shell Higgs boson at the LHC, we have presented a calculation of the one-loop SM contributions to the HZZ coupling, which can be written in terms of two CP-conserving $h_{1,2}^V$ and one CP-violating h_3^V form factors, where V stands for the off-shell Higgs boson. Since measurements at future LHC Runs could be sensitive to the potential effects of any anomalous contributions to this Higgs boson coupling, an up-to-date calculation is necessary to disentangle any anomalous effects from its SM contributions. We first obtain general results for the contributions to the $H^*Z^*Z^*$ coupling via the BFM in terms of Passarino-Veltman scalar functions, which are too lengthy to be presented here, but are available for the interested reader at our GitLab repository [75]. From such general results, the corresponding contributions to the H^*ZZ^* couplings can be straightforwardly obtained and are reported in Appendix B.

We then present an analysis of the behavior of the H^*ZZ and HZZ^* couplings, with focus on the effects of their absorptive parts, which have been overlooked in the past. For the numerical analysis, we consider the most popular parametrizations used in the literature, and the relationships necessary to map from one to another parametrization are obtained. We choose to work in the parametrization of Eq. (6) as it allows one to express the h_2^V form factor in terms of only one anomalous coupling. It is found that the main one-loop SM contribution to the h_2^V (V = H, Z) form factor arises from Feynman diagrams with a virtual W gauge boson. Although h_2^H can be as large as 10^{-2} at low energies, in general, both h_2^H and h_2^Z can be of the order of $10^{-3} - 10^{-4}$ at high energies. By means of our analytical results and the current constraints on the HZZ coupling ratios reported by the CMS collaboration, we obtain new bounds on the anomalous HZZ couplings, which are of the order of $10^{-2} - 10^{-4}$ depending on the value of the transfer momentum of the off-shell boson. It is worth emphasizing that while the limits on the real parts of the anomalous HZZ couplings are up to two orders of magnitude tighter than the previous ones, the bounds on the absorptive parts are a novel contribution as no previous limits of this kind have been reported before.

To assess the potential effects of the absorptive parts of the HZZ anomalous couplings, we estimate their contributions to the partial decay width $\Gamma_{H^*\to ZZ}$, which are compared with the SM tree-level contribution. It is found that at low energies the anomalous contributions can yield a deviation on $\Gamma_{H^*\to ZZ}$ up to 3% from the SM tree-level result, whereas at high energies there is a negligibly deviation. Along this line, polarized Z gauge bosons could be useful for the study of non-SM contributions via a new left-right asymmetry \mathcal{A}_{LR} , which is sensitive to CP-violating complex form factors. Such asymmetry can be as large as the unity for large values of the CP-violating form factor, but it is of the order of $10^{-3} - 10^{-4}$ in a more conservative scenario. Such values are indeed still larger by five or four orders of magnitude than the SM prediction for \mathcal{A}_{LR} , which has a non-vanishing contribution up to the three-loop level.

The partial decay widths $\Gamma_{H^* \to Z_L Z_L}$ and $\Gamma_{H^* \to Z_R Z_R}$ are also studied in several scenarios of new physics and a comparison is made with the tree and one-loop level SM contributions. Once again, significant deviations from the SM results are due to the *CP*-violating *HZZ* form factor. It is observed that such deviations can be large at high

energies, and become even larger as the energy increases. Thus, for polarized Z gauge bosons, there is a broad energy interval where the measurements could be sensitive to anomalous contributions, in contrast with the case of unpolarized Z gauge bosons, where there is only sensitivity to anomalous contributions at low energies. Thus, new physics effects may be searched for via the four-lepton final state of the process $H^* \to ZZ \to 4\ell$.

Appendix A: Parametrization mappings

In this appendix se present explicit expressions for the relations between the coupling constants appearing in the parametrization of Eq. (6) and those of the LHC framework and the SMEFT.

1. LHC Framework

Using the kinematics for $H^* \to ZZ$, the interaction of Eq. (12), which is used at the LHC analyses, can be rewritten in terms of the h_i^V form factors of Eq. (2) as follows

$$h_1^H(q^2, p_1^2, m_Z^2) = \frac{a_1^{ZZ}}{2} + \frac{\kappa_1^{ZZ} p_1^2 + \kappa_2^{ZZ} p_2^2}{2(\Lambda_1^{ZZ})^2} + \frac{a_2^{ZZ}}{2} \frac{q^2 - p_1^2 - p_2^2}{m_Z^2},\tag{A1}$$

$$h_2^H(q^2, p_1^2, m_Z^2) = -a_2^{ZZ}, \tag{A2}$$

$$h_3^H(q^2, p_1^2, m_Z^2) = -a_3^{ZZ}.$$
 (A3)

By matching with Eqs. (3), (4) and (5) from the Hagiwara basis, we obtain

$$1 + a_Z = \frac{a_1^{ZZ}}{2},\tag{A4}$$

$$-b_Z \frac{q^2 - p_1^2 - p_2^2}{m_Z^2} + c_Z \frac{q^2}{m_Z^2} = \frac{\kappa_1^{ZZ} p_1^2 + \kappa_2^{ZZ} p_2^2}{2(\Lambda_1^{ZZ})^2} + \frac{a_2^{ZZ}}{2} \frac{q^2 - p_1^2 - p_2^2}{m_Z^2},$$
(A5)

$$b_Z - c_Z = -\frac{a_2^{ZZ}}{2},\tag{A6}$$

$$\widetilde{b}_Z = -\frac{a_3^{ZZ}}{2},\tag{A7}$$

which yields the following relationship

$$c_Z \frac{p_1^2 + p_2^2}{m_Z^2} = \frac{\kappa_1^{ZZ} p_1^2 + \kappa_2^{ZZ} p_2^2}{2(\Lambda_1^{ZZ})^2}.$$
(A8)

In the case of $\kappa_1^{ZZ}=\kappa_2^{ZZ}$ and $\Lambda_1^{ZZ}\equiv m_Z$ we obtain

$$c_Z = \frac{\kappa_1^{ZZ}}{2}.\tag{A9}$$

On the other hand, from the basis of Lagrangian (6) given by Eqs. (7), (8) and (9), we obtain the relations

$$-\hat{b}_Z \frac{q^2 - p_1^2 - p_2^2}{m_Z^2} + \frac{\hat{c}_Z}{2} \frac{p_1^2 + p_2^2}{m_Z^2} = \frac{\kappa_1^{ZZ} p_1^2 + \kappa_2^{ZZ} p_2^2}{2(\Lambda_1^{ZZ})^2} + \frac{a_2^{ZZ}}{2} \frac{q^2 - p_1^2 - p_2^2}{m_Z^2}$$
(A10)

$$\hat{b}_Z = -\frac{a_2^{ZZ}}{2},\tag{A11}$$

whereas Eqs. (A4) and (A7) remain valid. For $\kappa_1^{ZZ} = \kappa_2^{ZZ}$ and $\Lambda_1^{ZZ} \equiv m_Z$, we obtain

$$\hat{c}_Z = \kappa_1^{ZZ}.\tag{A12}$$

Therefore, the parametrization of the H^*ZZ vertex given by Eq. (12) is redundant since only the form factor k_1^{ZZ} is necessary in both bases. In this work we have considered the relations (A4), (A7), (A11) and (A12).

2. SMEFT

The Lagrangian of Eq. (16) can be straightforwardly written in a more familiar form

$$\mathcal{L} = \frac{g}{2c_W m_Z} H \Big[(1 + \delta c_z) m_Z^2 Z_\mu Z^\mu + c_{zz} \frac{g_L^2 + g_Y^2}{4} Z_{\mu\nu} Z^{\mu\nu} + c_{z\Box} g_L^2 Z_\mu \partial_\nu Z^{\mu\nu} + \widetilde{c}_{zz} \frac{g_L^2 + g_Y^2}{4} Z_{\mu\nu} \widetilde{Z}^{\mu\nu} \Big], \tag{A13}$$

which allows one to identify the following relations with the form factors of Lagrangian (6)

$$\delta c_z = a_Z \tag{A14}$$

$$c_{zz} = \frac{4}{g_L^2 + g_Y^2} \hat{b}_Z, \tag{A15}$$

$$c_{z\square} = \frac{1}{g_L^2} \hat{c}_Z,\tag{A16}$$

$$\widetilde{c}_{zz} = \frac{4}{g_L^2 + g_Y^2} \widetilde{b}_Z,\tag{A17}$$

they agree with the relations reported in Ref. [53]. The mappings with the form factors of the Hagiwara basis follows easily from the relations of Sec. II.

Appendix B: Analytical results

In this Appendix we present the analytical expression for the one-loop contributions to the HZZ form factor h_2^V of Eq. (17) in terms of Passarino-Veltman scalar functions, which are obtained from our general results for the form factors of the $H^*Z^*Z^*$ coupling available as a Mathematica code at our gitlab site [75].

We first present the convention used for the two- and three-point Passarino-Veltman scalar functions:

$$B_0(r^2, m_1^2, m_2^2) = \frac{1}{i\pi^2} \int \frac{d^D k}{(k^2 - m_1^2)((k+r)^2 - m_2^2)},$$
(B1)

$$C_0(r_1^2, (r_1 + r_2)^2, r_2^2, m_1^2, m_2^2, m_3^2) = \frac{1}{i\pi^2} \int \frac{d^D k}{(k^2 - m_1^2)((k + r_1)^2 - m_2^2)((k + r_2)^2 - m_3^2)},$$
(B2)

and introduce the following shorthand notation

$$B_{0ij}(r^2) = B_0(r^2, m_i^2, m_j^2),$$

$$C_{0ijk}(q^2) = C_0(m_Z^2, m_Z^2, q^2, m_i^2, m_j^2, m_k^2),$$

$$C_{0ijk}(p_1^2) = C_0(m_H^2, m_Z^2, p_1^2, m_i^2, m_j^2, m_k^2).$$
(B3)

It is useful to note that the following symmetry relations are obeyed:

$$B_{ij}(r^2) = B_{ji}(r^2),$$

$$C_{ijk}(q^2) = C_{kji}(q^2),$$
(B4)

1. Contributions to the H^*ZZ coupling

The fermion contributions to the ${\cal A}^{\cal H}_{Vf,Af}$ functions read as

$$A_{Vf}^{H}(q^{2},m_{Z}^{2}) = \frac{1}{q^{2} (q^{2} - 4m_{Z}^{2})^{2}} \Big\{ 4q^{2}m_{Z}^{2} \Big[B_{0ff}(q^{2}) - B_{0ff}(m_{Z}^{2}) - 3 \Big] + 8m_{Z}^{4} \Big[B_{0ff}(q^{2}) - B_{0ff}(m_{Z}^{2}) + 2 \Big] \\ - \left(q^{2} - 2m_{Z}^{2}\right) \left(-4m_{f}^{2} \left(q^{2} - 4m_{Z}^{2}\right) - 6q^{2}m_{Z}^{2} - 4m_{Z}^{4} + q^{4}\right) C_{0fff}(q^{2}) + 2q^{4} \Big\},$$
(B5)

$$A_{Af}^{H}(q^{2},m_{Z}^{2}) = \frac{1}{q^{2}(q^{2}-4m_{Z}^{2})^{2}} \left\{ \left(q^{2}-2m_{Z}^{2}\right) \left(4\left(q^{2}-m_{Z}^{2}\right) \left[B_{0ff}\left(q^{2}\right)-B_{0ff}\left(m_{Z}^{2}\right)\right] + \left(-2m_{Z}^{2}\left(8m_{f}^{2}+q^{2}\right)+4q^{2}m_{f}^{2}+4m_{Z}^{4}+q^{4}\right) C_{0}\left(q^{2},m_{Z}^{2},m_{Z}^{2},m_{f}^{2},m_{f}^{2},m_{f}^{2}\right) + 2\left(q^{2}-4m_{Z}^{2}\right) \right\}.$$
 (B6)

As for the contributions from W gauge boson (W), and H - Z boson (\mathcal{HZ}) exchange, they are given by

$$\begin{aligned} A_W^H(q^2, m_Z^2) &= \frac{1}{8q^2(q^2 - 4m_Z^2)^2} \Big\{ 2\Big(\big(1 - 2c_W^2\big)^2 m_H^2 m_Z^2 \big(2m_Z^2 + q^2\big) + 2m_W^2 \big(\big(12c_W^4 - 4c_W^2 - 7\big)q^2 m_Z^2 \\ &+ \big(24c_W^4 - 8c_W^2 + 2\big)m_Z^4 + 2q^4\big) \Big) \Big[B_{0WW}(m_Z^2) - B_{0WW}(q^2) \Big] - 2\Big(\big(1 - 2c_W^2\big)^2 m_H^2 \big(2m_Z^4 \big(q^2 - m_Z^2\big) \\ &+ m_W^2 \big(- 6q^2 m_Z^2 + 8m_Z^4 + q^4\big) \big) + 2m_W^2 \big(4c_W^2 \big(1 - 2c_W^2\big)q^6 + 2\big(32c_W^4 - 16c_W^2 + 1\big)q^4 m_Z^2 \\ &- 2\big(52c_W^4 - 28c_W^2 + 3\big)q^2 m_Z^4 + \big(12c_W^4 - 4c_W^2 + 1\big)m_W^2 \big(- 6q^2 m_Z^2 + 8m_Z^4 + q^4\big) \\ &+ \big(- 24c_W^4 + 8c_W^2 - 2\big)m_Z^6 \big) \Big) C_{0WWW}(q^2) + \big(- 6q^2 m_Z^2 + 8m_Z^4 + q^4\big) \big(- \big(1 - 2c_W^2\big)^2 m_H^2 \\ &- 2\big(12c_W^4 - 4c_W^2 + 1\big)m_W^2 \big) \Big\}, \end{aligned}$$
(B7)

and

$$A_{ZH}^{H}(q^{2}, m_{Z}^{2}) = \frac{1}{8q^{2}(q^{2} - 4m_{Z}^{2})^{2}} \left\{ -2(m_{Z}^{2} - m_{H}^{2})(q^{2} - 4m_{Z}^{2}) \left[m_{Z}^{2} B_{0ZZ}(0) - m_{H}^{2} B_{0HH}(0) \right] + (6m_{H}^{4}(q^{2} - m_{Z}^{2}) - 9q^{2}m_{H}^{2}m_{Z}^{2}) B_{0HH}(q^{2}) + 2(8m_{Z}^{4}(m_{H}^{2} - q^{2}) - q^{2}m_{H}^{4} + 2m_{Z}^{2}(2q^{2}m_{H}^{2} - m_{H}^{4} + q^{4})) B_{0HZ}(m_{Z}^{2}) - (2q^{2}m_{H}^{4} + m_{Z}^{2}(3q^{2}m_{H}^{2} - 2m_{H}^{4} + 4q^{4}) - 18q^{2}m_{Z}^{4} + 8m_{Z}^{6}) B_{0ZZ}(q^{2}) + m_{H}^{2} \left(\left(-2m_{H}^{4}(q^{2} - m_{Z}^{2}) - m_{H}^{2}(-2q^{2}m_{Z}^{2} + 4m_{Z}^{4} + q^{4}) - 6q^{4}m_{Z}^{2} + 28q^{2}m_{Z}^{4} - 16m_{Z}^{6}) C_{0ZHZ}(q^{2}) - 3(2m_{H}^{4}(q^{2} - m_{Z}^{2}) + m_{H}^{2}(8m_{Z}^{4} - 8q^{2}m_{Z}^{2}) + q^{2}m_{Z}^{2}(2m_{Z}^{2} + q^{2})) C_{0HZH}(q^{2}) \right) + (4m_{Z}^{2} - q^{2})(2m_{H}^{2}(q^{2} - 4m_{Z}^{2}) + 2m_{H}^{4} + q^{2}m_{Z}^{2}) \right\}.$$
(B8)

2. Contributions to the HZZ^* coupling

The corresponding contributions to the HZZ^{\ast} coupling can be written as

$$\begin{aligned} A_{Vf}^{Z}(p_{1}^{2},m_{Z}^{2},m_{H}^{2}) &= \frac{1}{\left(-2m_{H}^{2}\left(m_{Z}^{2}+p_{1}^{2}\right)+m_{H}^{4}+\left(m_{Z}^{2}-p_{1}^{2}\right)^{2}\right)^{2}} \left\{ \left(2\left[m_{H}^{4}\left(m_{Z}^{2}+p_{1}^{2}\right)-2m_{H}^{2}\left(-4p_{1}^{2}m_{Z}^{2}+m_{Z}^{4}+p_{1}^{4}\right)\right.\right. \\ &+ \left(m_{Z}^{2}-p_{1}^{2}\right)^{2}\left(m_{Z}^{2}+p_{1}^{2}\right)\right] \right) B_{0ff}(m_{H}^{2}) + \left(-2m_{Z}^{2}\left[4p_{1}^{2}\left(m_{H}^{2}+m_{Z}^{2}\right)\right. \\ &+ \left(m_{H}^{2}-m_{Z}^{2}\right)^{2}-5p_{1}^{4}\right] \right) B_{0ff}(m_{Z}^{2}) + \left(-2p_{1}^{2}\left[m_{H}^{2}\left(4m_{Z}^{2}-2p_{1}^{2}\right)+m_{H}^{4}+4p_{1}^{2}m_{Z}^{2}\right. \\ &- 5m_{Z}^{4}+p_{1}^{4}\right] \right) B_{0ff}(p_{1}^{2}) + \left(\left(m_{H}^{2}-m_{Z}^{2}-p_{1}^{2}\right)\left[-p_{1}^{4}\left(-4m_{f}^{2}+3m_{H}^{2}+m_{Z}^{2}\right)\right. \\ &- p_{1}^{2}\left(8m_{f}^{2}\left(m_{H}^{2}+m_{Z}^{2}\right)-10m_{H}^{2}m_{Z}^{2}-3m_{H}^{4}+m_{Z}^{4}\right) + \left(m_{H}^{2}-m_{Z}^{2}\right)^{2}\left(4m_{f}^{2}-m_{H}^{2}+m_{Z}^{2}\right) \\ &+ p_{1}^{6}\right] \right) C_{0fff}(p_{1}^{2}) + 2\left[-3m_{H}^{4}\left(m_{Z}^{2}+p_{1}^{2}\right)+m_{H}^{2}\left(2p_{1}^{2}m_{Z}^{2}+3m_{Z}^{4}+3p_{1}^{4}\right)+m_{H}^{6} \\ &- \left(m_{Z}^{2}-p_{1}^{2}\right)^{2}\left(m_{Z}^{2}+p_{1}^{2}\right)\right] \right\}, \end{aligned}$$
