(Dated: March 16, 2023)

We find that there exists a universal law of coiling not only for a long elastic strip contacting within a tube but also for a short one. Here the elastic strip we consider has the ratio of $2 < L/R \leq 2\pi$ for its length L to the tube radius R . By varying the ratio of L/R , we identify four types of deformation for such a short elastic strip, namely, two point-contact, three point-contact, continuous-contact, and self-contact. With theoretical formulas in closed forms and experimental demonstration, these four types are verified for any elastic strips contacting within a tube, irrespective of elastic properties, strip lengths, and tube radius. Our results on coiling can be readily applied to a variety of physical systems, including thin flexible electronic devices, van der Waals materials in scroll shape, and DNA packaging into viral capsids.

Introduction.—Packing a long wire, fiber, or strip inside a container happens in many different systems, such as folding elastic wire in a spherical cavity [1–8], bending graphene sheets or van der Waals material in scroll shapes [9–12], packing DNA into viral capsids [13–21], and curling sheets in confirmed structures [22–24].

By considering a long elastic strip inside a smooth and solid cylindrical tube, a universal law of coiling was discovered [25, 26]. Irrespective of the tube size, the total strip length, and the elastic bending stiffness, when an elastic strip intrinsically flat is coiled inside a tube, the innermost strip is detached from the tube wall at multiple-layered curls. With free-of-friction contact forces between strip-strip and strip-tube interfaces, the tangential angle of a detached strip at the free end to the tube's tangent is 24.1° ; while the opening angle, subtended from the detached region, is 125.2° [25, 26].

This universal phenomenon was derived in theory first, then has been observed on a variety of surprisingly different length scales and in unexpected systems, including mechanical, biological, and condensed matters. Although experimental measurements and theoretical analyses suggest that the classical elastic plate model deviates to describe the bending deformation of monolayer graphene due to absence of in-plane σ -bonding, the continuum plate phenomenology can still be well employed in glued multilayers due to the mediation of van der Waals force [9–12].

Instead of long strips, in this *Letter*, we reveal that there also exists a universal law of coiling for a short elastic strip contacting within a tube. Here, we refer to a short strip as one with a ratio of the strip length L to the tube radius R between $2 < L/R \leq 2\pi$. With the help of Kirchhoff's equations for an elastica, we first theoretically identify four types of deformation for such a short elastic strip in Fig. 1, labelled, (a) two point-contact, (b) three point-contact, (c) continuous-contact, and (d) self-contact, which are characterized for arbitrary elastic materials. In experiments, see

the illustrations in Figs. 1(e)-(h), we fabricate samples in polyvinyl chloride (PVC) and polyethylene terephthalate (PET) with different lengths and thickness to verify our theoretical prediction, resulting in good agreement. As similar scenarios of such a short strip can be easily found in a wide range of physical systems, our results on coiling a short elastic strip can be readily applied to thin flexible electronic devices, photovoltaic solar cells, van der Waals materials, and DNA packaging.

Theory: Kirchhoff's equations.—As illustrated in Figs. 1(a-d), we model an intrinsically flat strip as a quasi one-dimensional elastica. Based on Kirchhoff's theory, the force and moment equations in the static equilibrium read [27, 28],

$$\frac{d\vec{F}(s)}{ds} + \vec{K}(s) = 0, \quad (1)$$

$$\frac{d\vec{M}(s)}{ds} + \hat{t}(s) \times \vec{F}(s) = 0. \quad (2)$$

Here, s is the arc-length along the elastic strip, $\hat{t}(s)$ is the unit tangent vector, $\vec{K}(s)$ is the external force per unit length, $\vec{F}(s)$ and $\vec{M}(s)$ denote resultant stress force and moment at s , respectively. In our theoretical analysis, we assume the elastica free of external bending moment, i.e., without friction between strip-strip and strip-tube interfaces and free of gravity. In case of a planar deformation, we have $\vec{M} = B\hat{t} \times d\hat{t}/ds$. Here B is the bending stiffness composed by $B = YI$, with Y being Young's modulus and I being the moment of inertia, which is equivalent to the quadratic form of curvature in the bending free energy [28]. Based on Eqs. (1-2), we start our analyses by increasing the stripe length ratio L/R : from slightly larger than 2 to 2π and reveal the emergence of four different types of deformation.

Two point-contact.—First of all, we consider the strip length slightly larger than $2R$, resulting in only two

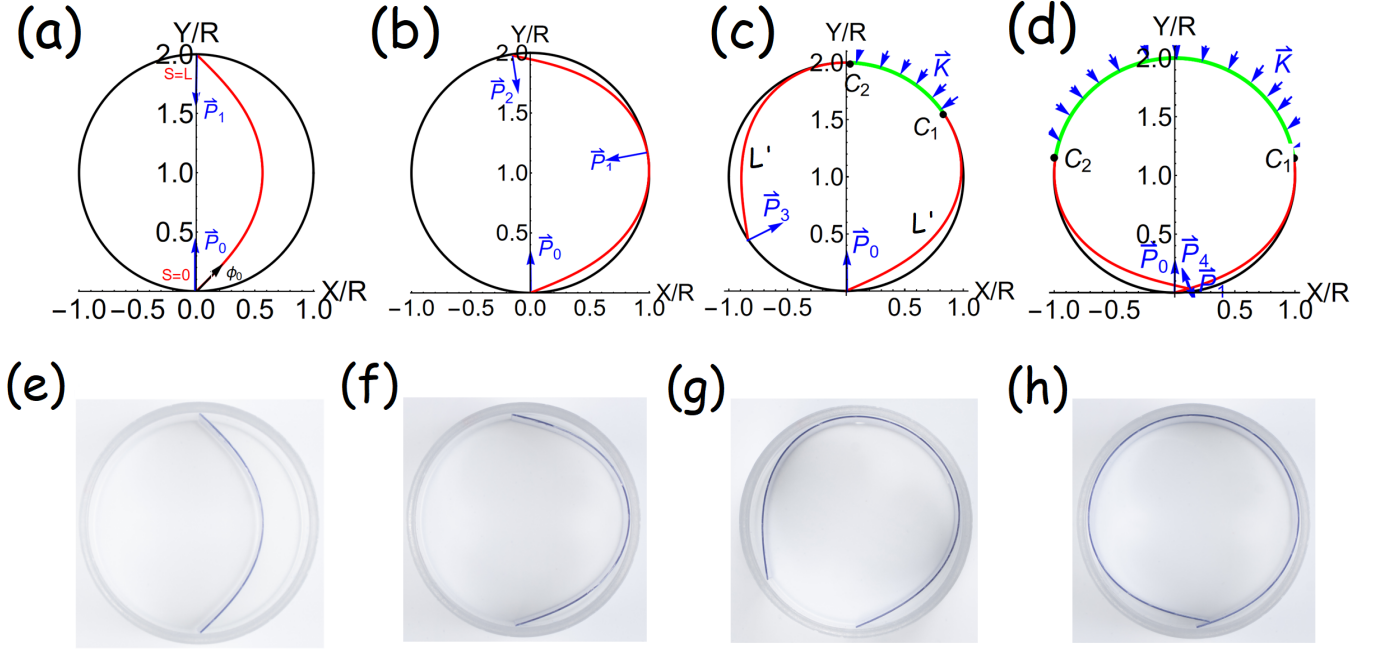

FIG. 1. Four different types of deformations are identified as the universal law of coiling, when the ratio of the strip length L to the tube radius R is $2 < L/R \leq 2\pi$. The First row (a)-(d) shows the simulation results for (a) $L/R = 2.37$, (b) 3.2, (c) 5.1, and (d) 2π , respectively. Here the red curves denote the detached strips; while the green curves denote the continuous contact parts of the strips. The Second row (e)-(h) shows the corresponding experimental measurements as a comparison (see Table 1 for more details). Here, the four types of deformations are (a, e) two point-contact, (b, f) three point-contact, (c, g) continuous-contact, and (d, h) self-contact. Related force analysis diagrams are also depicted in (a-d), denoted in blue colors.

point-contacts upon the strip at $s = 0$ and $s = L$, as the numerical calculation shown in Fig. 1(a), as well as the corresponding experimental illustration in Fig. 1(e).

Now, the associated point-contact forces at $s = 0$ and $s = L$ are \vec{P}_0 and \vec{P}_1 , respectively, as blue arrows in Fig. 1(a). Due to absence of friction, the directions of external forces is normal to the tube wall. Moreover, in static equilibrium, we have $\vec{P}_0 = -\vec{P}_1$. With $\vec{K} = 0$, by Eq. (1), the stress force $\vec{F}(s)$ is constant throughout the strip, i.e., $\vec{F}(s) = -\vec{P}_0$. By resorting to moment balance of Eq. (2), one can obtain a curvature equation,

$$\frac{d\phi(s)}{ds} = \sqrt{\frac{2P_0}{B}(\sin\phi - \sin\phi_0)}. \quad (3)$$

Here, $P_0 = |\vec{P}_0|$ and $\phi(s)$ is the tangential angle with respect to X-axis. Moreover, we denote $\phi_0 \equiv \phi(s = 0)$, and use a zero moment condition at $s = 0$, corresponding to $d\phi/ds|_{s=0} = 0$. As the length of the strip projected onto the Y-axis is always $2R$ and the strip length L is conserved, we thus have two geometric constraints:

$$R = \int_{\phi_0}^{\frac{\pi}{2}} \frac{\sin\phi}{\sqrt{\frac{2P_0}{B}(\sin\phi - \sin\phi_0)}} d\phi, \quad (4)$$

$$\frac{L}{2} = \int_{\phi_0}^{\frac{\pi}{2}} \frac{1}{\sqrt{\frac{2P_0}{B}(\sin\phi - \sin\phi_0)}} d\phi, \quad (5)$$

in which two unknowns ϕ_0 and P_0 are involved. Then, by eliminating P_0 , consequently ϕ_0 can be calculated for a given value of L/R , irrespective of bending stiffness B , but under the crucial geometric constraint for the strip at $s = L/2$, i.e., $0 \leq X(s = L/2)/R < 1$.

Accordingly, we numerically find the condition to support ϕ_0 and reach the constraint $0.358 < \phi_0 \leq \pi/2$, which gives us the corresponding strip length in this two point-contact region:

$$L/R \in [2, 3.033]; \text{ two point-contact region.} \quad (6)$$

We want to remark that this result holds for any elastic strip systems. As we increase L/R , the strip bends more, reflecting a monotonous decrease of ϕ_0 as shown in Fig. 2(a). Furthermore, with Eqs. (4-5), one can also introduce a dimensionless force:

$$\frac{P_0 R^2}{B} = \frac{1}{2} \left[\int_{\phi_0}^{\frac{\pi}{2}} \frac{\sin\phi}{\sqrt{\sin\phi - \sin\phi_0}} d\phi \right]^2, \quad (7)$$

which is a function of ϕ_0 . In Fig. 2(b), we display this dimensionless force $P_0 R^2/B$ as a function of L/R . In this two point-contact region, although this dimensionless force $P_0 R^2/B$ monotonously decreases as L/R increases, when with material property and stripe length (B and L) are fixed, the associated point-contact force P_0 increases for a short radius R . The value of $P_0 R^2/B = 2.47$ at $L/R = 2$ corresponds to the critical

force for the classical Euler's buckling bifurcation with $B\pi^2/L^2$ [28–30].

Three point-contact.—When the middle segment of the strip ($s = L/2$) makes a point contact with the tube, a three point-contact situation occurs, as illustrated from numerical calculation and experimental measurement in in Figs. 1(b) and 1(f), respectively. Here, as shown in Fig. 1(b), we denote three external point-contact forces upon the strip as \vec{P}_0 , \vec{P}_1 , and \vec{P}_2 . In the static equilibrium, their vectorial sum is zero.

By applying mirror symmetry to the strip, we conclude that the magnitudes of these external forces at two free ends are identical $|\vec{P}_0| = |\vec{P}_2| = P_0$, although their direction is different. Again, in the detached region from $s = 0$ and $s = L/2$, due to absence of external forces we also have $\vec{F}(s) = -\vec{P}_0$. Then, by employing the geometric constraint for point-contact and that the strip length L is conserved, as well as the zero moment at free ends, two unknowns can be determined: the tangential angles with respect to X-axis at $s = 0$ and $s = L/2$, i.e., ϕ_0 and $\phi_1 \equiv \phi(s = L/2)$ can be determined through the following conditions,

$$R \sin \phi_1 = \int_{\phi_0}^{\phi_1} \frac{\cos \phi}{\sqrt{\frac{2P_0}{B} [\sin \phi - \sin \phi_0]}} d\phi, \quad (8)$$

$$R - R \cos \phi_1 = \int_{\phi_0}^{\phi_1} \frac{\sin \phi}{\sqrt{\frac{2P_0}{B} [\sin \phi - \sin \phi_0]}} d\phi. \quad (9)$$

Again, by eliminating the unknown P_0 for a given value of L/R , we can sufficiently determine ϕ_0 and ϕ_1 , independently of B . The detailed derivation is given in Supplementary Materials.

By requiring the radius of curvature at $s = L/2$ being R , corresponding to the onset of continuous-contact, we can find out the supported values of $\phi_0 = 0.358 = 20.51^\circ$, which defines the maximum strip length obeying the three point-contact situation:

$$L/R \in [3.033, 4.176]; \text{ three point-contact region.} \quad (10)$$

The corresponding dimensionless force $P_0 R^2/B$ for the three point-contact case is

$$\frac{P_0 R^2}{B} = \frac{2(\sin \phi_1 - \sin \phi_0)}{\sin^2 \phi_1}, \quad (11)$$

which has an implicit dependence on L/R . When $L/R = 3.033$, the emergent point-contact at the middle strip makes \vec{P}_2 have a horizontal component in order to obey static equilibrium. In this way, the strength of \vec{P}_2 along the vertical direction would be decreased, leading to reduce $|\vec{P}_0|$ in Fig. 2 (b). As a result, when the length ratio $L/R > 3.033$ the tangential angle ϕ_0 increases, as shown in the inset of Fig. 2 (a).

Continuous-contact.—When $d\phi/ds|_{s=L/2}$ becomes $1/R$, the strip deformation switches to continuous contact, as

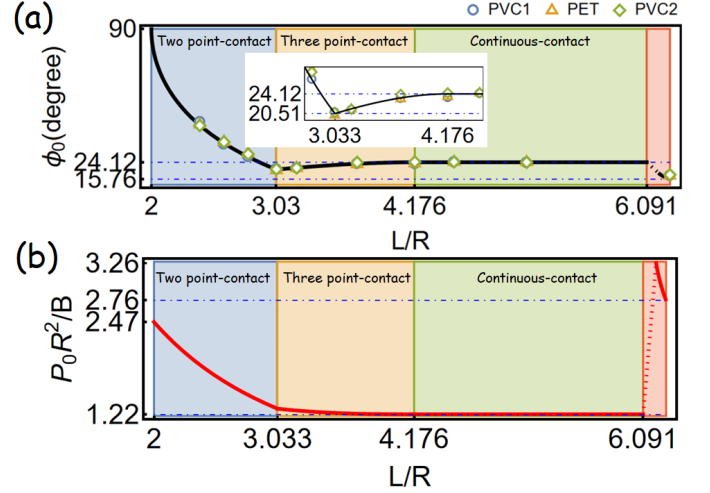

FIG. 2. (a) In terms of the length ratio L/R , we identify different deformation regions through numerical simulations for the tangential angle ϕ_0 (black curve), and three sets of experimental measurements: \circ (0.5mm thickness of PVC, denoted as PVC1), \diamond (0.1mm thickness of PVC, denoted as PVC2), and \triangle (0.2mm thickness of PET, denoted as PET). (b) The corresponding dimensionless force $P_0 R^2/B$ is also depicted as a function of the length ratio L/R .

illustrated in in Figs. 1(c) and 1(g) from numerical and experimental results, respectively. Now, we have a finite region making continuous contact with the tube, as marked by the green colored curve in Fig. 1(c). The associated pressure distribution \vec{K} exerted by the tube remains constant in magnitude [31].

We mark the two ends of this continuous contact as C_1 and C_2 . By considering the geometric constraint of the curvature at C_1 being $1/R$, as well as zero moment at the free end $s = 0$, again one can have the following two equations involving two unknown tangential angles at $s = 0$ and $s = L'$,

$$2 \sin \phi_0 = \sin \phi_1, \quad (12)$$

$$\frac{\sin \phi_1}{1 - \cos \phi_1} = \frac{\int_{\phi_0}^{\phi_1} \frac{\cos \phi}{\sqrt{(\sin \phi - \sin \phi_0)}} d\phi}{\int_{\phi_0}^{\phi_1} \frac{\sin \phi}{\sqrt{(\sin \phi - \sin \phi_0)}} d\phi}. \quad (13)$$

For details see Supplementary Materials.

By numerical calculation, we obtain that the tangential angle at the free end is $\phi_0 = 0.421 = 24.12^\circ$; while the opening angle is $\phi_1 = 2.185 = 125.2^\circ$. Interestingly, these two angles are exactly the same angles for a long stripe [25, 26]. The curvature equation for this detached strip, as well as that boundary conditions, return to the same scenario as that of multiple layered curls. We indicate this result in Fig. 2(a), in which ϕ_0 is always 24.12° .

By taking the dimensionless force at $s = 0$, i.e., $P_0 R^2/B = 1/\sin \phi_1 = 1.22$, into the curvature equation for the detached strip, the detached length can be numerically found to be $L'/R = 2.088$. This ratio also reflects the minimum length permitted in the continuous-contact

deformation, i.e., $2L'$. However, the continuous-contact deformation will be terminated when two free ends of the strip meet at $(X/R, Y/R) = (0, 0)$. Accordingly, we can derive the maximum length for the continuous contact situation by $2L' + R(2\pi - 2\phi_1) = 6.091R$. Therefore, the supported strip length for this continuous-contact region is bounded by

$$L/R \in [4.176, 6.091]; \text{ continuous-contact region.} \quad (14)$$

We want to emphasize that the corresponding dimensionless force $P_0 R^2/B$ in this continuous-contact region, somewhat counter-intuitively, remains constant, as the numerical results show in Fig. 2 (b).

Self-contact.—Last but not least, we consider the strip length in the self-contact region:

$$L/R > 6.091; \text{ self-contact region.} \quad (15)$$

Now, the strip self-contacts, as illustrated in Figs. 1(d) and 1(h) from simulation and experiment, respectively. Here, one free end of the strip makes a point-contact with the front side of the tube. At this stage, the point-contact is accompanied with internal point forces, as denoted by \vec{P}_1 and \vec{P}_4 shown in Fig. 1(d). By Newton's third law, we have $\vec{P}_1 = -\vec{P}_4$. As a result, the interaction among different segmental parts of the strip leads to a nonlocal effect. Moreover, there still exists a finite continuous-contact region, marked by the green colored curve in Fig. 1(d), in association with the pressure distribution \vec{K} .

Interestingly, only two external point forces are upon the whole strip. One is the point-contact force at $s = 0$, denoted as \vec{P}_0 , and the other one is the pressure \vec{K} from the tube. Since the null of friction is still valid in our system, the direction of the point contact force at $s = 0$ is vertical. Consequently, in order to maintain the static equilibrium, the pressure distribution \vec{K} needs to be a symmetric distribution with respect to Y-axis. This implies that the positions of C_1 and C_2 form mirror symmetry with respect to the Y-axis. The detailed derivation can be found in the Supplementary Materials.

In Fig. 2 (b), we also calculate the corresponding dimensionless point-contact force at $s = 0$. Since the emergence of internal force is close to $s = 0$ in our case, the dimensionless point-contact force $P_0 R^2/B$ can be expectedly to be larger than that in the continuous-contact region. At $L/R = 2\pi$, we find $P_0 R^2/B = 2.76$. Consequently, the pushing force \vec{P}_1 causes the front strip downward, resulting in ϕ_0 decreasing with respect to L/R , as shown in Fig. 2(a).

Experimental verification.—We design and fabricate a series of different stripe lengths L/R , from 2.4 to 6.28, see Table 1 for more details. In experiments, we prepare two different elastic materials: polyvinyl chloride (PVC) and polyethylene terephthalate (PET), but also with dif-

Length Ratio L/R	PVC 0.5mm	PET 0.2mm	PVC 0.1mm	Theoretical Values, ϕ_0
2.4	43.9°	42.8°	42.3°	42.37°
2.6	33.1°	34.2°	34.1°	33.55°
2.8	26.7°	28.6°	28.1°	26.78°
3.03	20.8°	20.2°	20.7°	20.5°

TABLE I. Experimental measurements on the tangential angle ϕ_0 from different stripe length ratio L/R . Here, we have three sets in material parameters: 0.5mm thickness of PVC (PVC1), 0.2 mm thickness of PET (PET), and 0.2mm thickness of PVC (PVC2). Theoretical values are also listed for the comparison.

ferent thickness in order to verify our theoretical findings. Three sets of material parameters are performed: 0.5mm thickness of PVC (PVC1), 0.2 mm thickness of PET (PET), and 0.1mm thickness of PVC (PVC2). All the samples are 2 cm wide. The elastic strips are also prepared in initially flat condition, i.e., in the absence of tube confinement, to avoid any plastic deformation. The tube used is acrylic (polymethylmethacrylate, PMMA). It has an inner radius of 3 cm.

With the tangential angle at $s = 0$, denoted as ϕ_0 , the measured tangential angles from three sets of PVC1, PET, and PVC2, are listed in Table 1, along with the comparison to the theoretical values. All the obtained data are also plotted in Fig. 2(a), as well as the selected pictures shown in Fig. 1(e)-(h). They show good agreements with our simulation curves for two point-contact, three point-contact, and continuous-contact regions. When the length of strip satisfies $4.176 \leq L/R \leq 6.091$, the measured ϕ_0 confirms the theoretical value 24.12° according to prediction from the continuous contact case.

Conclusion.—In addition to the universal law of coiling for a long stripe, we find theoretically and experimentally that a short elastic strip contacting within a tube, with the length ratio $2 < L/R \leq 2\pi$, also follows universal behavior. Four different types of deformation: two point-contact, three point-contact, continuous-contact, and self-contact, are identified in theory and verified in experiments. Theoretically, the boundaries between two adjunct regions of deformation are characterized by elastic Kirchhoff's equations; while experimentally three sets of material parameters, with a series of different lengths, are investigated, resulting in good agreement with our theoretical analysis. Our results show the existence of a universal law even for a short strip, irrespective of elastic properties, strip lengths, and tube radii. The results in this work can be readily applied to many practical applications, ranging, e.g., from flexible electronic devices, medical fibre imaging, to DNA packaging.

 - [31] The curvature of the the continuous contact region is constant, $\phi_s = \frac{1}{R}$, so $\vec{M}_s = 0$. Then by considering moment balance of Eq.(1), it leads to $\hat{t} \times \vec{F} = 0$, then we obtain $f_n = 0$. Here $\vec{F} = f_t \hat{t} + f_n \hat{n}$ expressed in intrinsic coordinate, for a planar deformation. Here \hat{n} is unit normal vector. Furthermore, by considering force balance of Eq.(1) and taking $\vec{K}(s) = K \hat{n}$, we find that $f_t = \text{constant}$ and $K = -\frac{f_t}{R} = \text{constant}$ [33]. The direction of \vec{K} is changed with respect to s , while its magnitude is constant, $|\vec{K}| = \text{constant}$.
 - [32] By moment balance of Eq.(1), we can obtain a relation for normal stress force, $f_n = -B\phi_{ss}$. Here the stress force we use is expressed in terms of intrinsic co-

ordinate, $\vec{F} = f_t \hat{t} + f_n \hat{n}$. Taking this result into force balance of Eq.(1), in the tangential direction, we find $(f_t)_s = f_n \phi_s = -B \phi_s \phi_{ss}$. By integration with respect to s , we have $f_t(s') + \frac{1}{2} B \phi_s^2(s') = \text{constant}$. This is conservation relation for tangential stress force f_t and curvature ϕ_s , valid for any location of the strip.

[33] By using Frenet-Serret equations for a planar deformation, we have the following relations: $\frac{d\hat{t}}{ds} = \phi_s \hat{n}$ and $\frac{d\hat{n}}{ds} = -\phi_s \hat{t}$.

I. TWO POINT-CONTACT REGION

Figure 3(a) gives an example of the two point-contact scenario. Here, we have $L/R = 2.37$ in numerical calculation. Here, the origin of coordinate (X,Y) is referred to the bottom of the tube, where is also the onset of the strip, i.e., $s = 0$. Related force analysis diagram is also illustrated in Fig. 3 (a). There are two external point-contact forces, denoted as \vec{P}_0 and \vec{P}_1 , upon two ends of the strip.

From the force balance, we obtain $\vec{P}_0 = -\vec{P}_1$. And due to free of friction, we have $\vec{P}_0 = P_0 \hat{y}$. We denote ϕ_0 and ϕ_1 as the corresponding tangential angles of the strip with respect to X-axis at $s = 0$ and $s = L$, respectively. In our coordinate, the unit tangential vector has the form: $\hat{t} = \frac{dx}{ds} \hat{x} + \frac{dy}{ds} \hat{y} = \cos \phi(s) \hat{x} + \sin \phi(s) \hat{y}$. As we only have two-point contacts, from Eq. (1) in the main text, we read $\vec{F}_s = 0$. Therefore the stress force at each cross section of the strip is constant, i.e., $\vec{F} = -\vec{P}_0 = -P_0 \hat{y}$.

Resorting to the moment balance of Eq. (1), we obtain a curvature equation,

$$\frac{d\phi(s)}{ds} = \phi(s)_s = \sqrt{\frac{2P_0}{B} (\sin \phi - \sin \phi_0)}. \quad (16)$$

Here we already apply a zero moment at $s = 0$, corresponding to $\phi_s(0) = 0$. Since the length of the strip projected to Y-axis is always R and the strip length L is conserved, we thus have two geometric constraints:

$$R = \int_{\phi_0}^{\frac{\pi}{2}} \frac{\sin \phi}{\sqrt{\frac{2P_0}{B} (\sin \phi - \sin \phi_0)}} d\phi, \quad (17)$$

$$\frac{L}{2} = \int_{\phi_0}^{\frac{\pi}{2}} \frac{d\phi}{\sqrt{\frac{2P_0}{B} (\sin \phi - \sin \phi_0)}} d\phi, \quad (18)$$

in which two unknowns ϕ_0 and P_0 are involved. With above equations, one can eliminate P_0 and reach

$$\frac{2R}{L} = \frac{\int_{\phi_0}^{\frac{\pi}{2}} \frac{\sin \phi}{\sqrt{\sin \phi - \sin \phi_0}} d\phi}{\int_{\phi_0}^{\frac{\pi}{2}} \frac{d\phi}{\sqrt{\sin \phi - \sin \phi_0}}}. \quad (19)$$

Therefore we determine ϕ_0 with a given value of L/R .

Now we define a dimensionless force by $\frac{P_0 R^2}{B^2}$, which has the form:

$$\frac{P_0 R^2}{B} = \frac{1}{2} \left[\int_{\phi_0}^{\frac{\pi}{2}} \frac{\sin \phi}{\sqrt{\sin \phi - \sin \phi_0}} d\phi \right]^2, \quad (20)$$

as a function of ϕ_0 .

We remark that in this two point-contact region, a crucial geometric constraint is that the position of the middle part of the strip projected to x-axis is bound by

$$0 \leq x \leq R \Rightarrow 1 - \frac{1}{4} \left[\int_{\phi_0}^{\frac{\pi}{2}} \frac{\sin \phi}{\sqrt{\sin \phi - \sin \phi_0}} d\phi \right]^2 \leq \sin \phi_0 \quad (21)$$

Here, we already apply P_0 from Eq. (20) and $x = \int_{\phi_0}^{\frac{\pi}{2}} \frac{\cos \phi}{\sqrt{\frac{2P_0}{B} (\sin \phi - \sin \phi_0)}} d\phi = \sqrt{\frac{2B}{P_0}} [1 - \sin \phi_0]$. By solving above condition, we then obtain

$$0.358 \leq \phi_0 < \frac{\pi}{2}. \quad (22)$$

Next, combined with Eq. (19), the strip length in this two point-contact region is bounded by

$$L/R \in [2, 3.033], \quad (23)$$

which is valid for any elastic materials.

Once we determine ϕ_0 and P_0 , the shape of elastic strip can be numerically calculated through

$$\begin{aligned} x(\phi') &= \int_{\phi_0}^{\phi'} \frac{\cos \phi}{\sqrt{\frac{2P_0}{B} (\sin \phi - \sin \phi_0)}} d\phi = \sqrt{\frac{2B}{P_0}} [\sin \phi' - \sin \phi_0] \\ y(\phi') &= \int_{\phi_0}^{\phi'} \frac{\sin \phi}{\sqrt{\frac{2P_0}{B} (\sin \phi - \sin \phi_0)}} d\phi, \end{aligned} \quad (24)$$

where $\phi' = [\phi_0, \pi - \phi_0]$. An example of two point-contact deformation for $L/R = 2.37$ is illustrated in Figure 3(a).

II. THREE POINT-CONTACT REGION

When $L/R > 3.033$, the strip encounters three external forces, denoted as \vec{P}_0 , \vec{P}_1 , and \vec{P}_2 . The corresponding tangential angles of the strip with respect to X-axis are denoted as ϕ_0 , ϕ_1 , and ϕ_2 , respectively. We note that in this stage the curvature of the strip at the middle part is larger than $1/R$, corresponding to a point contact. On the other hand, from the force balance, it leads to $\vec{P}_0 + \vec{P}_1 + \vec{P}_2 = 0$. Now, we introduce another angle coordinate β , with respect to $-Y$ axis, as shown in Fig. 3(b), as an auxiliary coordinate. Thus, the coordinates of these contact-points can be written as

$$\vec{R}(\beta) = R \sin \beta \hat{x} + (R - R \cos \beta) \hat{y}, \quad (25)$$

with $\beta = [\beta_0, \beta_1, \beta_2]$. With the auxiliary coordinate, we have $\beta_1 = \phi_1$, but $\phi_0 \neq \beta_0$ and $\phi_2 \neq \beta_2$. As a result, the corresponding point-contact forces are

$$\vec{P}_0 = P_0 \hat{y}, \quad (26)$$

$$\vec{P}_1 = P_1 (-\sin \beta_1 \hat{x} + \cos \beta_1 \hat{y}), \quad (27)$$

$$\vec{P}_2 = P_2 (-\sin \beta_2 \hat{x} + \cos \beta_2 \hat{y}). \quad (28)$$

With mirror symmetry, we have $|\vec{P}_0| = |\vec{P}_2| = P_0$. Then, by force balance, one obtain $\vec{P}_0 + \vec{P}_1 + \vec{P}_2 = 0$, or equivalently,

$$\hat{x} : -P_1 \sin \beta_1 = P_0 \sin \beta_2 \quad (30)$$

$$\hat{y} : P_0 + P_1 \cos \beta_1 + P_0 \cos \beta_2 = 0. \quad (31)$$

Then, we find

$$\tan \beta_1 = \frac{\sin \beta_2}{1 + \cos \beta_2}, \quad (32)$$

$$P_1 = -\frac{P_0 \sin \beta_2}{\sin \beta_1}. \quad (33)$$

Once we determine β_1 (ϕ_1) and P_0 , β_2 and P_1 can be obtained.

Further more, we divide the detached strips into two regions, denoted as (1) and (2), marked by blue and green curves in Fig. 3(b). From the moment equation, a curvature equation for the region (1) can be obtained, i.e.,

$$\phi_s^{(1)} = \sqrt{\frac{2P_0}{B}(\sin \phi - \sin \phi_0)}. \quad (34)$$

Here we also apply a zero moment at $s = 0$, corresponding to $\phi_s(0) = 0$. Complemented by the geometry constraint for the middle part of the strip, we have the following conditions,

$$R \sin \phi_1 = \int_{\phi_0}^{\phi_1} \frac{\cos \phi d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}}, \quad (35)$$

$$R - R \cos \phi_1 = \int_{\phi_0}^{\phi_1} \frac{\sin \phi d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}}. \quad (36)$$

where we apply the condition of a continuous curvature at ϕ_1 , i.e., between the region (1) and the region (2). The

Again, by eliminating the unknown P_0 , we have

$$\frac{1 - \cos \phi_1}{\sin \phi_1} = \frac{\int_{\phi_0}^{\phi_1} \frac{\sin \phi d\phi}{\sqrt{\sin \phi - \sin \phi_0}}}{\int_{\phi_0}^{\phi_1} \frac{\cos \phi d\phi}{\sqrt{\sin \phi - \sin \phi_0}}}, \quad (37)$$

with two unknowns involved, i.e., ϕ_0 and ϕ_1 . For this segment of the strip, the corresponding length is

$$\frac{L}{2} = \int_{\phi_0}^{\phi_1} \frac{d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}}. \quad (38)$$

With Eqs. (35) and (38), we have

$$\int_{\phi_0}^{\phi_1} \frac{d\phi}{\sqrt{\sin \phi - \sin \phi_0}} = \frac{L}{R} \frac{\sqrt{\sin \phi_1 - \sin \phi_0}}{\sin \phi_1}. \quad (39)$$

Then, by considering a set of Eqs. (37) and (39):

$$\frac{1 - \cos \phi_1}{\sin \phi_1} = \frac{\int_{\phi_0}^{\phi_1} \frac{\sin \phi d\phi}{\sqrt{\sin \phi - \sin \phi_0}}}{\int_{\phi_0}^{\phi_1} \frac{\cos \phi d\phi}{\sqrt{\sin \phi - \sin \phi_0}}}, \quad (40)$$

$$\int_{\phi_0}^{\phi_1} \frac{d\phi}{\sqrt{\sin \phi - \sin \phi_0}} = \frac{L}{R} \frac{\sqrt{\sin \phi_1 - \sin \phi_0}}{\sin \phi_1}, \quad (41)$$

one can simultaneously solve ϕ_0 and ϕ_1 (β_1) when L/R is given.

The corresponding dimensionless force $\frac{P_0 R^2}{B}$ for the three point-contact case has the form:

$$\frac{P_0 R^2}{B} = \frac{2(\sin \phi_1 - \sin \phi_0)}{\sin^2 \phi_1}, \quad (42)$$

with an implicit dependence of L/R .

Regarding the other region (2), i.e., $s = [L/2, L]$, we have $\vec{F} = \vec{P}_2 = P_0(-\sin \beta_2 \hat{x} + \cos \beta_2 \hat{y})$, where β_2 can be calculated by using Eq. (32). Again, by using moment equation, the curvature equation for the region (2) is

$$\phi_s^{(2)} = \sqrt{\frac{2}{B}[P_0 \sin(\beta_2 - \phi) + \frac{2B(\sin \phi_1 - \sin \phi_0)^2}{R^2 \sin^2 \phi_1} - P_0 \sin(\beta_2 - \phi_1)]}, \quad (43)$$

curvature at $s = L/2$ is

$$\phi_s(\frac{L}{2}) = \frac{2(\sin \phi_1 - \sin \phi_0)}{R \sin \phi_1}. \quad (44)$$

For this detached region (2), the corresponding length is defined by

$$\frac{L}{2} = \int_{\phi_1}^{\phi_2} \frac{d\phi}{\sqrt{\frac{2}{B}[P_0 \sin(\beta_2 - \phi) + \frac{2B(\sin \phi_1 - \sin \phi_0)^2}{R^2 \sin^2 \phi_1} - P_0 \sin(\beta_2 - \phi_1)]}}, \quad (45)$$

which can be used to determine ϕ_2 , i.e., tangential angle at $s = L$.

The three-point contact region will be terminated when the curvature at the middle plate meets $\phi_s(\frac{L}{2}) = \frac{2(\sin \phi_1 - \sin \phi_0)}{R \sin \phi_1} = \frac{1}{R}$, resulting in the continuous-contact region. Consequently, the strip length for three-point contact situation is bounded by

$$L/R \in [3.033R, 4.176], \quad (46)$$

which is again valid for any elastic materials. In Fig. 3(b), we illustrate such a three point-contact deformation from the numerical calculation with $L/R = 3.2$.

III. CONTINUOUS-CONTACT REGION

When $L/R > 4.176$, we enter the continuous-contact region, as illustrated in Fig. 3(c). Here, the boundaries of the continuous-contact are defined as C_1 and C_2 , with its tangential angles as ϕ_1 and ϕ_2 , respectively. The corresponding force analysis diagram is also shown in Fig. 3(c). Now, there are two point-contact forces \vec{P}_0 and \vec{P}_3 and a continuous-contact pressure \vec{K} . Here, \vec{K} is pressure de-

fined as force per unit length. The tangential angles of the strip at \vec{P}_0 and \vec{P}_3 with respect to X-axis are denoted as ϕ_0 and ϕ_3 , respectively.

By considering mirror symmetry for the strip, we have $|\vec{P}_0| = |\vec{P}_3| = P_0$ and the detached shapes, denoted as (1) and (3), are expected to be identical. It is noted that within this continuous-contact region, its curvature remains $1/R$. Bu a properly chosen coordinate, we also have $\phi_1 = \beta_1$ and $\phi_2 = \beta_2$. Now, for the region (1), the stress force is constant, i.e., $\vec{F} = -\vec{P}_0 = -P_0\hat{y}$. with the help of moment balance, we read

$$\phi_s^{(1)} = \sqrt{\frac{2P_0}{B}}(\sin \phi - \phi_0), \quad (47)$$

where a zero moment at $s = 0$, corresponding to $\phi_s(0) = 0$ is used. As the curvature at C_1 is $\frac{1}{R}$, one can have

$$\frac{1}{R} = \sqrt{\frac{2P_0}{B}}(\sin \phi_1 - \phi_0). \quad (48)$$

Since C_1 is confined by the tube, we therefore have the geometric constraints:

$$R \sin \phi_1 = \int_{\phi_0}^{\phi_1} \frac{\cos \phi}{\sqrt{\frac{2P_0}{B}(\sin \phi - \sin \phi_0)}} d\phi = \sqrt{\frac{2B}{P_0}}(\sin \phi_1 - \sin \phi_0), \quad (49)$$

$$R - R \cos \phi_1 = \int_{\phi_0}^{\phi_1} \frac{\sin \phi}{\sqrt{\frac{2P_0}{B}(\sin \phi - \sin \phi_0)}} d\phi. \quad (50)$$

By eliminating P_0 , we reach the following equation

$$\frac{\sin \phi_1}{1 - \cos \phi_1} = \frac{\int_{\phi_0}^{\phi_1} \frac{\cos \phi}{\sqrt{(\sin \phi - \sin \phi_0)}} d\phi}{\int_{\phi_0}^{\phi_1} \frac{\sin \phi}{\sqrt{(\sin \phi - \sin \phi_0)}} d\phi}. \quad (51)$$

By taking Eq. (48) into the first term of Eq. (49), we obtain

$$2 \sin \phi_0 = \sin \phi_1. \quad (52)$$

Consequently, we have a set of Eqs. (51) and (52),

$$2 \sin \phi_0 = \sin \phi_1, \quad (53)$$

$$\frac{\sin \phi_1}{1 - \cos \phi_1} = \frac{\int_{\phi_0}^{\phi_1} \frac{\cos \phi}{\sqrt{(\sin \phi - \sin \phi_0)}} d\phi}{\int_{\phi_0}^{\phi_1} \frac{\sin \phi}{\sqrt{(\sin \phi - \sin \phi_0)}} d\phi}, \quad (54)$$

where two unknowns, i.e., ϕ_0 and ϕ_1 are involved, which

can be sufficiently determined, independent from the elastic bending moment B and tube radius R . Numerically, we obtain

$$\phi_0 = 0.421 = 24.1^\circ, \quad (55)$$

$$\phi_1 = 2.185 = 125.2^\circ. \quad (56)$$

The results reveal that the tangential angle of the free end is $\phi_0 = 0.421 = 24.12^\circ$; while the opening angle is $\phi_1 = \beta_1 = 2.185 = 125.2^\circ$, valid for any elastic material and tube size, referring to universal law of coiling.

The corresponding dimensionless force $P_0 R^2/B$ in this continuous contact region is

$$\frac{P_0 R^2}{B} = \frac{1}{\sin \phi_1} = 1.22. \quad (57)$$

Moreover, we formulate the detached length of the region (1), defined as L' ,

$$\frac{L'}{R} = \frac{1}{R} \int_{\phi_0}^{\phi_1} \frac{d\phi}{\sqrt{\frac{2P_0}{B}(\sin\phi - \sin\phi_0)}} = \sqrt{\frac{\sin\phi_1}{2}} \int_{\phi_0}^{\phi_1} \frac{d\phi}{\sqrt{\sin\phi - \sin\phi_0}} = 2.088. \quad (58)$$

Here, we already apply Eq. (57) with $\phi_0 = 0.421$ and $\phi_1 = 2.185$. This result defines the minimum length for the emergence of the continuous contact, i.e., $2L'$. On the other hand, the maximum length before the self-contact situation occurs with

$$2\frac{L'}{R} + (2\pi - 2\beta_1). \quad (59)$$

Here, $2L'/R$ denotes the total length of detached region; while $(2\pi - 2\beta_1)$ denotes the length of the continuous-contact region. As a result the strip length for this continuous-contact is bounded by

$$L \in [4.176R, 6.091R], \quad (60)$$

which is valid for any elastic materials.

For the region (3), due to mirror symmetry of the strip, β_2 (here $\beta_2 = \phi_2$) can be found by

$$\beta_2 = \frac{L - 2L'}{R} + \beta_1. \quad (61)$$

By geometry, we have

$$\beta_3 = \beta_1 + \beta_2. \quad (62)$$

We note that the tangential angle at $s = L$ end, i.e., ϕ_3 , is not the same as β_3 . By using the detached length condition, we can have ϕ_3 by

$$\frac{L'}{R} = \frac{1}{R} \int_{\phi_2}^{\phi_3} \frac{d\phi}{\sqrt{\frac{2P_0}{B}(\sin[\phi_3 - \beta_3] - \sin[\phi - \beta_3])}} = 2.088. \quad (63)$$

The corresponding curvature equation for this detached region (3) has the form:

$$\phi_s^{(3)} = \sqrt{\frac{2P_0}{B}[\sin(\phi_3 - \beta_3) - \sin(\phi - \beta_3)]}. \quad (64)$$

The stress force at this detached region is $\vec{F}^{(3)} = q_0(-\sin\beta_3\hat{x} + \cos\beta_3\hat{y})$. An example of this continuous contact region is illustrated in Fig. 3(c) with numerical calculation for $L/R = 5.1$.

IV. SELF-CONTACT REGION

The deformation of self-contact occurs at

$$L/R > 6.091. \quad (65)$$

Due to the interaction among different segments of the strip emerges, the self-contact problem is nonlocal and highly nonlinear. As illustrated in Fig. 3(d), we divide the strip into four segments, denoted as (1), (2), (3), and (4), with the corresponding length L_1 , L_2 , L_3 , and L_4 , respectively. First of all, we have $L = L_1 + L_2 + L_3 + L_4$. Here, only the region (3) is subject to the continuous contact. We also denote ϕ_0 , ϕ_1 , ϕ_2 , ϕ_3 , and ϕ_4 are the tangential angles with respect to X-axis at $s = 0$ and the interface between regions (1)-(2), C_1 , C_2 , and $s = L$. Here C_1 and C_2 are the boundaries of the continuous contact.

With the help of force analysis diagram in Fig. 3(d), the external forces are \vec{P}_0 and pressure \vec{K} ; while \vec{P}_1 and \vec{P}_4 belong to internal forces. The continuous contact region is associated with the pressure \vec{K} by the tube with a constant in magnitude. On the other hand, since the direction of \vec{P}_0 is always toward Y-axis direction, in order to maintain the force balance, we can conclude that the pressure \vec{K} has to be symmetry with respect to Y-axis. Accordingly, a geometric relation for β_2 and β_3 can be constructed, i.e.,

$$\pi - \beta_2 = \beta_3 - \pi \Rightarrow \beta_2 + \beta_3 = 2\pi. \quad (66)$$

In the region (1), i.e., $s \in [0, L_1]$, the stress force is $\vec{F}^{(1)} = -\vec{P}_0 = -P_0\hat{y}$ and the corresponding curvature equation is $\phi_s^{(1)} = \sqrt{\frac{2P_0}{B}[\sin\phi - \sin\phi_0]}$.

Then, in the region (2), i.e., $s \in [L_1, L_2 + L_1]$, the stress force is $\vec{F}^{(2)} = -\vec{P}_0 - \vec{P}_1 = -P_1\sin\phi_1\hat{x} + [-P_0 + P_1\cos\phi_1]\hat{y}$. The corresponding curvature equation is $\phi_s^{(2)} = \sqrt{\frac{2}{B}[P_0\sin\phi - P_1\sin(\phi - \phi_1) - P_0\sin\phi_0]}$, where we apply the boundary conditions at $s = L_1$ and $s = L_2$.

Finally, in the region (4), the stress force is $\vec{F}^{(4)} = P_1(-\sin\phi_1\hat{x} + \cos\phi_1\hat{y})$. By Newton's third law, we have $\vec{P}_1 = -\vec{P}_4$. The curvature equation is $\phi_s^{(4)} = \sqrt{\frac{2P_1}{B}[\sin(\phi_4 - \phi_1) - \sin(\phi - \phi_1)]}$, where we also apply a zero moment at $s = L$, i.e., $\phi_s(L) = 0$. Now, we have six unknowns in this self-contact problem. They are

$$\phi_0, \phi_1, \beta_2, \phi_4, P_0, P_1. \quad (67)$$

To solve, we need six equations. First, the position at $s = L_1$ meets that at $s = L$. Then, we have

$$\int_{\phi_0}^{\phi_1} \frac{\cos \phi d\phi}{\sqrt{\frac{2P_0}{B} [\sin \phi - \sin \phi_0]}} = R \sin(\beta_3) + \int_{\beta_3}^{\phi_4} \frac{\cos \phi d\phi}{\sqrt{\frac{2P_1}{B} [\sin(\phi_4 - \phi_1) - \sin(\phi - \phi_1)]}}, \quad (68)$$

$$\int_{\phi_0}^{\phi_1} \frac{\sin \phi d\phi}{\sqrt{\frac{2P_0}{B} [\sin \phi - \sin \phi_0]}} = R - R \cos(\beta_3) + \int_{\beta_3}^{\phi_4} \frac{\sin \phi d\phi}{\sqrt{\frac{2P_1}{B} [\sin(\phi_4 - \phi_1) - \sin(\phi - \phi_1)]}}. \quad (69)$$

In addition, we also have a position condition at $s = L_1 + L_2$, i.e.,

$$R \sin \beta_2 = \int_{\phi_0}^{\phi_1} \frac{\cos \phi d\phi}{\sqrt{\frac{2P_0}{B} [\sin \phi - \sin \phi_0]}} + \int_{\phi_1}^{\beta_2} \frac{\cos \phi d\phi}{\sqrt{\frac{2}{B} [P_0(\sin \phi - \sin \phi_0) - P_1 \sin(\phi - \phi_1)]}}, \quad (70)$$

$$R - R \cos \beta_2 = \int_{\phi_0}^{\phi_1} \frac{\sin \phi d\phi}{\sqrt{\frac{2P_0}{B} [\sin \phi - \sin \phi_0]}} + \int_{\phi_1}^{\beta_2} \frac{\sin \phi d\phi}{\sqrt{\frac{2}{B} [P_0(\sin \phi - \sin \phi_0) - P_1 \sin(\phi - \phi_1)]}}. \quad (71)$$

We also have the total strip length L as

$$L = \int_{\phi_0}^{\phi_1} \frac{d\phi}{\sqrt{\frac{2P_0}{B} [\sin \phi - \sin \phi_0]}} + \int_{\phi_1}^{\beta_2} \frac{d\phi}{\sqrt{\frac{2}{B} [P_0(\sin \phi - \sin \phi_0) - P_1 \sin(\phi - \phi_1)]}} \quad (72)$$

$$+ R(\beta_3 - \beta_2) + \int_{\beta_3}^{\phi_4} \frac{d\phi}{\sqrt{\frac{2P_1}{B} [\sin(\phi_4 - \phi_1) - \sin(\phi - \phi_1)]}}. \quad (73)$$

With the conservation relation, one can obtain

$$\frac{B}{2R^2} - P_0 \sin \phi_2 + P_1 \sin(\phi_2 - \phi_1) = -P_0 \sin \phi_0. \quad (74)$$

Finally, we summarize a set of six equations for these six unknowns:

$$\int_{\phi_0}^{\phi_1} \frac{\cos \phi d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}} = R \sin(\beta_3) + \int_{\beta_3}^{\phi_4} \frac{\cos \phi d\phi}{\sqrt{\frac{2P_1}{B}[\sin(\phi_4 - \phi_1) - \sin(\phi - \phi_1)]}}, \quad (75)$$

$$\int_{\phi_0}^{\phi_1} \frac{\sin \phi d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}} = R - R \cos(\beta_3) + \int_{\beta_3}^{\phi_4} \frac{\sin \phi d\phi}{\sqrt{\frac{2P_1}{B}[\sin(\phi_4 - \phi_1) - \sin(\phi - \phi_1)]}}, \quad (76)$$

$$R \sin \beta_2 = \int_{\phi_0}^{\phi_1} \frac{\cos \phi d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}} + \int_{\phi_1}^{\beta_2} \frac{\cos \phi d\phi}{\sqrt{\frac{2}{B}[P_0(\sin \phi - \sin \phi_0) - P_1 \sin(\phi - \phi_1)]}}, \quad (77)$$

$$R - R \cos \beta_2 = \int_{\phi_0}^{\phi_1} \frac{\sin \phi d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}} + \int_{\phi_1}^{\beta_2} \frac{\sin \phi d\phi}{\sqrt{\frac{2}{B}[P_0(\sin \phi - \sin \phi_0) - P_1 \sin(\phi - \phi_1)]}}, \quad (78)$$

$$L = \int_{\phi_0}^{\phi_1} \frac{d\phi}{\sqrt{\frac{2P_0}{B}[\sin \phi - \sin \phi_0]}} + \int_{\phi_1}^{\beta_2} \frac{d\phi}{\sqrt{\frac{2}{B}[P_0(\sin \phi - \sin \phi_0) - P_1 \sin(\phi - \phi_1)]}} \quad (79)$$

$$+ R(\beta_3 - \beta_2) + \int_{\beta_3}^{\phi_4} \frac{d\phi}{\sqrt{\frac{2P_1}{B}[\sin(\phi_4 - \phi_1) - \sin(\phi - \phi_1)]}}, \quad (80)$$

$$\frac{B}{2R^2} - P_0 \sin \phi_2 + P_1 \sin(\phi_2 - \phi_1) = -P_0 \sin \phi_0, \quad (81)$$

where $\beta_2 + \beta_3 = 2\pi$. As example, Fig. 3(d) illustrates the self-contact scenario, when the free end $s = L$ makes

a point-contact with the front side of the strip. Here we use $L/R = 7$ in the numerical calculation.

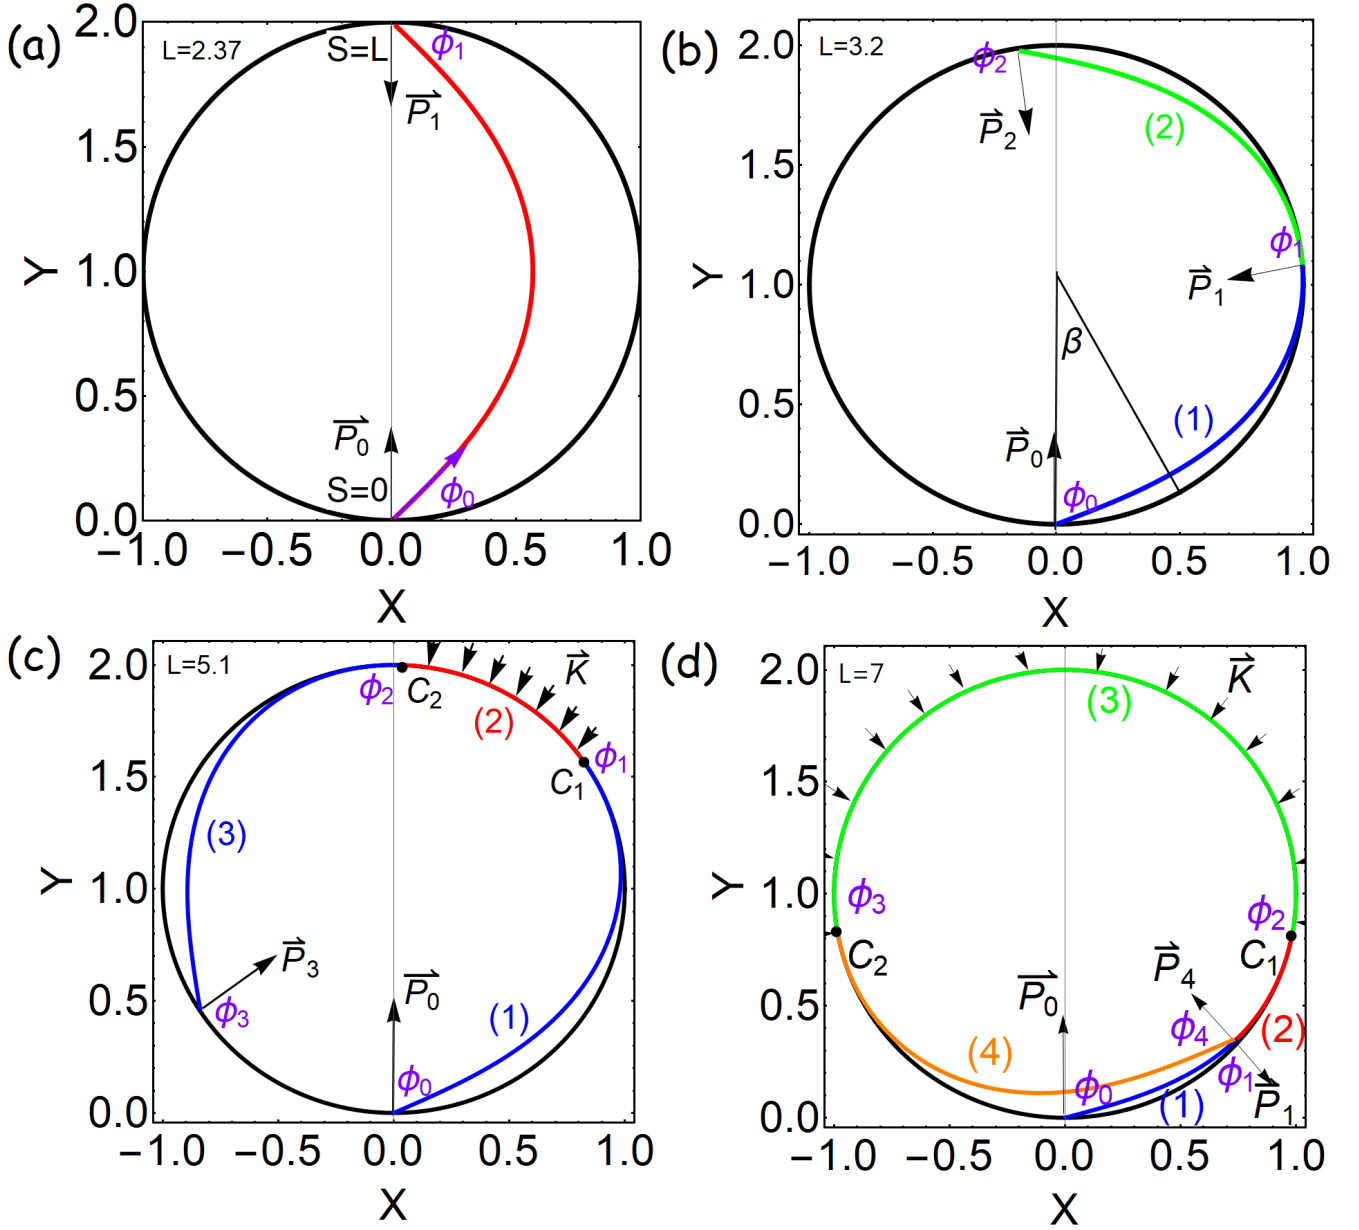

FIG. 3. (a) Deformation of two point-contact by numerical calculation with $L/R = 2.37$. The external forces normal to the tube wall at $s = 0$ and $s = L$ are denoted as \vec{P}_0 and \vec{P}_1 , respectively. Here, ϕ_0 and ϕ_1 are the tangential angles with respect to the X-axis at $s = 0$ and $s = L$. (b) Deformation of three point-contact by numerical calculation with $L/R = 3.2$. There are three external point-contact forces upon the strip, denoted as \vec{P}_0 , \vec{P}_1 , and \vec{P}_2 . The corresponding tangential angles of the strip at $s = 0$, $s = \frac{L}{2}$, and $s = L$, are ϕ_0 , ϕ_1 , and ϕ_2 , respectively. Here, we also employ another coordinate system β , with respect to the $-Y$ -axis, as an auxiliary coordinate to describe the geometric relation. (c) Deformation of continuous-contact by $L/R = 5.1$. There exists a finite continuous-contact region marked by a red curve, in association with the continuous contact pressure \vec{K} marked by black arrows. Here, C_1 and C_2 correspond to the boundary of the continuous contact region. ϕ_0 , ϕ_1 , ϕ_2 , and ϕ_3 are the corresponding tangential angles at $s = 0$, C_1 , C_2 , and $s = L$, respectively. (d) Deformation of self-contact by $L = 7R$. There still exists a continuous-contact region marked by a green curve, in association with pressure \vec{K} . Here, the external forces are from \vec{P}_0 at $s = 0$ and pressure \vec{K} occurred at the continuous-contact region. \vec{P}_1 and \vec{P}_4 as internal forces. The regions, (1), (2), and (4) are detached from the tube, marked by blue, red, and orange curves.
