#### Abstract

This paper considers the regularization continuation method and the trustregion updating strategy for the nonlinearly equality-constrained optimization problem. Namely, it uses the inverse of the regularization quasi-Newton matrix as the pre-conditioner to improve its computational efficiency in the well-posed phase, and it adopts the inverse of the regularization two-sided projection of the Hessian as the pre-conditioner to improve its robustness in the ill-conditioned phase. Since it only solves a linear system of equations at every iteration and the sequential quadratic programming (SQP) needs to solve a quadratic programming subproblem at every iteration, it is faster than SQP. Numerical results also show that it is more robust and faster than SQP (the built-in subroutine fmincon.m of the MATLAB2020a environment and the subroutine SNOPT executed in GAMS v28.2 (2019) environment). The computational time of the new method is about one third of that of fmincon.m for the large-scale problem. Finally, the global convergence analysis of the new method is also given.

Keywords continuation method • preconditioned technique • trust-region method • regularization technique - quasi-Newton method

## 1 Introduction

In this article, we consider the optimization problem with nonlinear equality constraints as follows:

$$
\begin{align*}
& \min _{x \in \mathfrak{R}^{n}} f(x) \\
& \text { subject to } c(x)=0 \tag{1}
\end{align*}
$$

where $f: \mathfrak{R}^{n} \rightarrow \mathfrak{R}$ and $c: \mathfrak{R}^{n} \rightarrow \mathfrak{R}^{m}(m \leq n)$. This problem has many applications in engineering fields such as the visual-inertial navigation of an unmanned aerial vehicle maintaining the horizontal flight [11,49], constrained sparse regression [8], sparse signal recovery $[20,83]$, image restoration and de-noising [21,57,77], the Dantzig selector [43], support vector machines [22], and sparse principal component analysis (PCA) methods [15, 86, 84]. And there are many practical methods [38,42,65] and many efficient solvers (the built-in subroutine fmincon [72] of MATLAB 2020a [60] and the subroutine SNOPT [29,30] in the GAMS environment [23]) to solve it based on the sequential quadratic programming (SQP) method $[31,70,85]$.

For the constrained optimization problem (1), the continuation method [3, 12, 24, $37,67,80]$ is another method other than the traditional optimization method such as SQP [31,70,71,85] or the penalty function method [17]. The advantage of the continuation method over the SQP method is that the continuation method is capable of finding many local optimal points of the non-convex optimization problem by tracking its trajectory, and it is even possible to find the global optimal solution [6,55, 73,87]. However, the computational efficiency of the classical continuation methods is lower than that of the traditional optimization method such as SQP. Recently, Luo et al intensively investigate the continuation methods for nonlinear equations [50,53], linear programming problems [51], linear complementarity problems [56], unconstrained optimization problems [52,55], and linearly constrained optimization problems $[49,54]$. And they obtain the more robust and faster continuation methods than the traditional optimization methods.

Here, we extend their ideas to the optimization problem with nonlinear equality constraints. In order to improve the computational efficiency of the continuation method for the large-scale optimization problem further, we consider the regularization BFGS (a special quasi-Newton method) preconditioned technique for the regularization continuation method and use an adaptive time step control based on the trust-region updating strategy in this article. Moreover, in order to improve its robustness, we replace the inverse of the regularization BFGS matrix with the inverse of the regularization two-sided projection of the Hessian matrix in the ill-posed phase.

The rest of the paper is organized as follows. In Section 2, we give the regularization continuation method with the switching preconditioned technique and the trust-region updating strategy for the problem (1). In Section 3, we analyze the global convergence of this new method. In Section 4, we report some promising numerical
results of the new method, in comparison to the state-of-art optimization methods (SQP, the built-in subroutine fmincon [72] of MATLAB 2020a [60] and the subroutine SNOPT [29,30] in the GAMS environment [23]) for some large-scale problems. Finally, we give some discussions and conclusions in Section 5.

## 2 The regularization continuation method

In this section, we give the regularization continuation method with the switching preconditioned technique and the adaptive time-stepping scheme based on the trustregion updating strategy [13] for the optimization problem with nonlinear equality constraints. Firstly, we consider the regularized projection gradient flow based on the KKT conditions of equality-constrained optimization problems. Then, we construct the regularization continuation method with the trust-region updating strategy to follow this special ordinary differential equations (ODEs). The new method uses the Broyden-Fletcher-Goldfarb-Shanno (BFGS) updating formula [5,18,25,76] as the preconditioned technique to improve its computational efficiency in the well-posed phase, and it adopts the inverse of the regularized two-sided projection Hessian as the pre-conditioner to improve its robustness in the ill-posed phase. Furthermore, we use the generalized continuation Newton method [53] to find an initial feasible point.

### 2.1 The regularized projection Newton flow

For the nonlinearly constrained optimization problem (1), it is well known that its optimal solution $x^{*}$ needs to satisfy the Karush-Kuhn-Tucker conditions (p. 328, [65]) as follows:

$$
\begin{align*}
\nabla_{x} L(x, \lambda) & =\nabla f(x)+A(x)^{T} \lambda=0,  \tag{2}\\
c(x) & =0, \tag{3}
\end{align*}
$$

where $A(x)^{T}=\left[\nabla c_{1}(x), \ldots, \nabla c_{m}(x)\right]$ and the Lagrangian function $L(x, \lambda)$ is defined by

$$
\begin{equation*}
L(x, \lambda)=f(x)+\lambda^{T} c(x) . \tag{4}
\end{equation*}
$$

Similarly to the method of the negative gradient flow for the unconstrained optimization problem [33], from the first-order necessary conditions (2)-(3), we can construct a dynamical system of differential-algebraic equations for problem (1) [14, 46, 47,48, $49,54,74]$ as follows:

$$
\begin{align*}
& \frac{d x}{d t}=-\nabla L_{x}(x, \lambda)=-\left(\nabla f(x)+A(x)^{T} \lambda\right)  \tag{5}\\
& c(x)=0 \tag{6}
\end{align*}
$$

By differentiating the algebraic constraint (6) with respect to $t$ and substituting it into the differential equation (5), we obtain

$$
\begin{align*}
& \frac{d c(x)}{d t}=A(x) \frac{d x}{d t}=-A(x)\left(\nabla f(x)+A(x)^{T} \lambda\right) \\
& =-A(x) \nabla f(x)-A(x) A(x)^{T} \lambda=0 . \tag{7}
\end{align*}
$$

If we assume that matrix $A(x)$ has full row rank further, from equation (7), we obtain

$$
\begin{equation*}
\lambda=-\left(A(x) A(x)^{T}\right)^{-1} A(x) \nabla f(x) . \tag{8}
\end{equation*}
$$

By substituting $\lambda$ of equation (8) into equation (5), we obtain the projected gradient flow [80] for the constrained optimization problem (1) as follows:

$$
\begin{equation*}
\frac{d x}{d t}=-\left(I-A(x)^{T}\left(A(x) A(x)^{T}\right)^{-1} A(x)\right) \nabla f(x)=-P(x) g(x) \tag{9}
\end{equation*}
$$

where $g(x)=\nabla f(x)$ and the projection matrix $P(x)$ is defined by

$$
\begin{equation*}
P(x)=I-A(x)^{T}\left(A(x) A(x)^{T}\right)^{-1} A(x) \tag{10}
\end{equation*}
$$

It is not difficult to verify $(P(x))^{2}=P(x)$. That is to say, the projection matrix $P(x)$ is symmetric and its eigenvalues are 0 or 1 . From Theorem 2.3.1 in p. 73 of [27], we know that its matrix 2 -norm is

$$
\begin{equation*}
\|P(x)\|=1 \tag{11}
\end{equation*}
$$

We denote $P(x)^{\dagger}$ as the Moore-Penrose generalized inverse of the projection matrix $P(x)$ (see p. 11, [79] or [64,68]). Since the projection matrix $P(x)$ is symmetric and $(P(x))^{2}=P(x)$, it is not difficult to verify

$$
\begin{equation*}
P(x)^{\dagger}=P(x) . \tag{12}
\end{equation*}
$$

Actually, from equation (12), we have $P(x)(P(x))^{\dagger} P(x)=P(x), P(x)^{\dagger} P(x) P(x)^{\dagger}=$ $P(x)^{\dagger},\left(P(x)^{\dagger} P(x)\right)^{T}=P(x)^{\dagger} P(x)$ and $\left(P(x) P(x)^{\dagger}\right)^{T}=P(x) P(x)^{\dagger}$.

Remark 1 If $x(t)$ is the solution of the ODE (9), it is not difficult to verify that $x(t)$ satisfies $A(x)(d x / d t)=0$. That is to say, if the initial point $x_{0}$ satisfies $c\left(x_{0}\right)=0$, the solution $x(t)$ of the projected gradient flow (9) also satisfies $c(x)=0, \forall t \geq 0$. This property is very useful such that we can construct an ODE method to follow the trajectory of the ODE (9) and obtain its steady-state solution $x^{*}$.

If we assume that $x(t)$ is the solution of the ODE (9), by using the property $(P(x))^{2}=P(x)$, we obtain

$$
\begin{aligned}
& \frac{d f(x)}{d t}=(\nabla f(x))^{T} \frac{d x}{d t}=-(\nabla f(x))^{T} P(x) \nabla f(x) \\
& =-g(x)^{T}(P(x))^{2} g(x)=-\|P(x) g(x)\|^{2} \leq 0 .
\end{aligned}
$$

That is to say, $f(x)$ is monotonically decreasing along the solution curve $x(t)$ of the dynamical system (9). Furthermore, the solution $x(t)$ converges to $x^{*}$ when $f(x)$ is lower bounded and $t$ tends to infinity [33,73,80], where $x^{*}$ satisfies the first-order Karush-Kuhn-Tucker conditions (2)-(3). Thus, we can follow the trajectory $x(t)$ of the ODE (9) to obtain its steady-state solution $x^{*}$, which is also one stationary point of the original optimization problem (1).

However, since the right-hand-side function $P(x) g(x)$ of the ODE (9) is rankdeficient, we will confront the numerical difficulties when we use the explicit ODE method to follow the projected gradient flow (9) [4,7,9]. In order to mitigate the stiffness of the ODE (9), we use the generalized inverse $\left(P(x) \nabla^{2} f(x) P(x)\right)^{\dagger}$ of the two-sided projection matrix $P(x) \nabla^{2} f(x) P(x)$ as the pre-conditioner for the ODE (9), which is used similarly to the system of nonlinear equations [50], the unconstrained optimization problem [33,52,55], the linear programming problem [51], the linear complementarity problem [56], the underdetermined system of nonlinear equations [49,54] and the linearly constrained optimization problem [54].

By using the generalized inverse $\left(P(x) \nabla^{2} f(x) P(x)\right)^{\dagger}$ of $P(x) \nabla^{2} f(x) P(x)$ as the pre-conditioner for the ODE (9), we obtain the projected Newton flow

$$
\begin{equation*}
\frac{d x(t)}{d t}=-\left(P(x) \nabla^{2} f(x) P(x)\right)^{\dagger} P(x) g(x) . \tag{13}
\end{equation*}
$$

Since $P(x) \nabla^{2} f(x) P(x)$ is singular, we reformulate equation (13) as

$$
\begin{equation*}
\left(P(x) \nabla^{2} f(x) P(x)\right) \frac{d x(t)}{d t}=-P(x) g(x) \tag{14}
\end{equation*}
$$

Although the projected Newton flow (14) mitigates the stiffness of the ODE such that we can adopt the explicit ODE method to integrate it on the infinite interval, there are two disadvantages. One is that the two-side projection matrix $P(x) \nabla^{2} f(x) P(x)$ may be not positive semi-definite. Consequently, it can not ensure the objective function $f(x)$ is monotonically decreasing along the solution $x(t)$ of the ODE (14). The other is that the solution $x(t)$ of the ODE (14) can not ensure to satisfy the feasibility, i.e., $d c(x) / d t=A(x) d x(t) / d t=0$. In order to overcome these two shortcomings, we use the regularization technique $[32,81,82]$ for the projected Newton flow (14) as follows:

$$
\begin{equation*}
\left(\sigma(x) I+P(x) \nabla^{2} f(x) P(x)\right) \frac{d x(t)}{d t}=-P(x) g(x) \tag{15}
\end{equation*}
$$

where the regularization parameter $\sigma(x)$ satisfies $\sigma(x)+\mu_{\text {min }}\left(P(x) \nabla^{2} f(x) P(x)\right) \geq$ $\sigma_{\text {min }}>0$. Here, $\mu_{\text {min }}(B)$ represents the smallest eigenvalue of matrix $B$.

Remark 2 If we assume that $x(t)$ is the solution of the $\operatorname{ODE}$ (15), from the property $A(x) P(x)=0$, we have

$$
A(x)\left(\sigma(x) I+P(x) \nabla^{2} f(x) P(x)\right) \frac{d x(t)}{d t}=-A(x) P(x) g(x)=0 .
$$

Consequently, we obtain $\sigma(x) A(x) d x(t) / d t=0$, i.e. $A(x) d x(t) / d t=0$. By integrating it, we obtain $c(x)=c\left(x_{0}\right)=0$. That is to say, the solution $x(t)$ of the ODE (15) preserves the feasibility $c(x)=0$ when $c\left(x_{0}\right)=0$.

Remark 3 From $(P(x))^{2}=P(x)$, we know that the solution $x(t)$ of the ODE (15) satisfies $P(x) d x(t) / d t=d x(t) / d t$. Consequently, from equation (15) and the assumption $\sigma(x)+\lambda_{\text {min }}\left(P(x) \nabla^{2} f(x) P(x)\right) \geq \sigma_{\text {min }}>0$, we obtain

$$
\begin{aligned}
& \frac{d f(x(t))}{d t}=(\nabla f(x))^{T} \frac{d x(t)}{d t}=(\nabla f(x))^{T} P(x) \frac{d x(t)}{d t}=(P(x) g(x))^{T} \frac{d x(t)}{d t} \\
& \quad=-(P(x) g(x))^{T}\left(\sigma(x) I+P(x) \nabla^{2} f(x) P(x)\right)^{-1}(P(x) g(x)) \leq 0
\end{aligned}
$$

That is to say, $f(x)$ is monotonically decreasing along the solution $x(t)$ of the ODE (15). Furthermore, the solution $x(t)$ converges to $x^{*}$ when $f(x)$ is lower bounded and $\left\|P(x) \nabla^{2} f(x) P(x)\right\| \leq M[33,41,73,80]$, where $M$ is a positive constant and $x^{*}$ is the stationary point of the regularization projected Newton flow (15). Thus, we can follow the trajectory $x(t)$ of the ODE (15) to obtain its stationary point $x^{*}$, which is also one stationary point of the original optimization problem (1).

### 2.2 The regularization continuation method

The solution curve $x(t)$ of the ODE (15) can not be efficiently followed by the general ODE method $[4,7,9,36]$ such as backward differentiation formulas (BDFs, the subroutine ode15s.m of the MATLAB R2020a environment [60]). Thus, we need to construct the particular method for this problem. We apply the first-order explicit Euler method [75] to the ODE (15), then we obtain the regularized projection Newton method as follows:

$$
\begin{align*}
& \left(\sigma_{k} I+P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)\right) d_{k}=-P\left(x_{k}\right) g\left(x_{k}\right),  \tag{16}\\
& x_{k+1}=x_{k}+\alpha_{k} d_{k}, \tag{17}
\end{align*}
$$

where $\alpha_{k}$ is the time step. When $\alpha_{k}=1$, the regularized projection Newton method (16)-(17) is similar to the Levenberg-Marquardt method [40,45,62].

Since the time step $\alpha_{k}$ of the regularized projection Newton method (16)-(17) is restricted by the numerical stability [75]. That is to say, for the linear test equation $d x / d t=-\lambda x$, its time step $\alpha_{k}$ is restricted by the stable region $\left|1-\alpha_{k} \lambda /\left(\sigma_{k}+\lambda\right)\right| \leq$ 1. In order to avoid this disadvantage, similarly to the processing technique of the nonlinear equations [50,51,53], the unconstrained optimization problem [52,54] and the linearly constrained optimization problem [54], we replace $\alpha_{k}$ with $\Delta t_{k} /\left(1+\Delta t_{k}\right)$ in equation (17) and let $\sigma_{k}=\sigma_{0} / \Delta t_{k}$ in equation (16). Then, we obtain the regularization continuation method:

$$
\begin{align*}
& \left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right) d_{k}=-P_{k} g_{k}, s_{k}^{p}=\frac{\Delta t_{k}}{1+\Delta t_{k}}\left(P_{k} d_{k}\right),  \tag{18}\\
& x_{k+1}^{p}=x_{k}+s_{k}^{p}, \tag{19}
\end{align*}
$$

where $\Delta t_{k}$ is the time step, $P_{k}=P\left(x_{k}\right), g_{k}=\nabla f\left(x_{k}\right)$ and $B_{k}=P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ or its quasi-Newton approximation.

We denote $A_{k}=A\left(x_{k}\right)$. The matrix $A_{k} A_{k}^{T}$ may be ill-conditioned. Thus, the Cholesky factorization method may fail to solve the projection matrix defined by equation (10) for the large-scale problem. Therefore, we use the QR decomposition (pp. 247-248, [27]) to solve it as follows:

$$
\begin{equation*}
A_{k}^{T}=Q_{k} R_{k}, \tag{20}
\end{equation*}
$$

where $Q_{k} \in \mathfrak{R}^{n \times m}$ satisfies $Q_{k}^{T} Q_{k}=I$ and $R_{k} \in \mathfrak{R}^{m \times m}$ is an upper triangle matrix. Consequently, the projection matrix $P_{k}$ defined by equation (10) can be simplified as follows:

$$
\begin{equation*}
P_{k}=I-Q_{k} Q_{k}^{T} \tag{21}
\end{equation*}
$$

From equations (18)-(19) and the property $A\left(x_{k}\right) P\left(x_{k}\right)=0$ of the projection matrix $P\left(x_{k}\right)$, it is not difficult to verify $A\left(x_{k}\right) s_{k}^{p}=0$. Thus, when the constraint is linear, i.e. $c(x)=A x-b=0, x_{k+1}^{p}$ also satisfies the linear constraint $A x_{k+1}^{p}-b=0$ if $A x_{k}-b=0$ [54]. However, for the nonlinear constraint $c(x)=0$, this property is not true. In other words, we may not have $c\left(x_{k+1}^{p}\right)=0$ when $c\left(x_{k}\right)=0$, where $x_{k+1}^{p}$ is the solution of equations (18)-(19). Therefore, we need to compute the correction step $s_{k}^{c}$ such that $x_{k+1}=x_{k+1}^{p}+s_{k}^{c}$ is pulled back to the constraint $c(x)=0$. In order to save the computational time, we use the following generalized Newton iteration with the shortest increment [53] to achieve this aim:

$$
\begin{align*}
& s_{k}^{c}=-\left(A_{k+1}^{p}\right)^{\dagger} c\left(x_{k+1}^{p}\right),\left(A_{k+1}^{p}\right)^{\dagger}=\left(A_{k+1}^{p}\right)^{T}\left(A_{k+1}^{p}\left(A_{k+1}^{p}\right)^{T}\right)^{-1} \\
& s_{k} \triangleq s_{k}^{p}+s_{k}^{c}, x_{k+1}=x_{k+1}^{p}+s_{k}^{c}=x_{k}+s_{k} \tag{22}
\end{align*}
$$

where $A_{k+1}^{p}$ equals $A\left(x_{k}\right)$ or $A\left(x_{k+1}^{p}\right)$. We first try $A_{k+1}^{p}=A\left(x_{k}\right)$ and solve equation (22). If $\left\|c\left(x_{k+1}\right)\right\|_{\infty}>\varepsilon_{0}$, we try $A_{k+1}^{p}=A\left(x_{k+1}^{p}\right)$ and solve equation (22) again, where $\varepsilon_{0}$ is a given small constant that is less than the termination tolerance $\varepsilon$ such as $\varepsilon_{0}=$ $\frac{1}{10} \varepsilon$ and $\varepsilon=10^{-6}$.

When $A_{k+1}^{p}=A\left(x_{k}\right)=A_{k}$, we have obtained its QR decomposition (20) and let $Q_{k}^{p}=Q_{k}, R_{k}^{p}=R_{k}$. If $A_{k+1}^{p}=A\left(x_{k+1}^{p}\right)$, we also use the QR decomposition (pp. 247248, [27]) to factorize it as $\left(A_{k+1}^{p}\right)^{T}=Q_{k}^{p} R_{k}^{p}$, where $Q_{k}^{p} \in \mathfrak{R}^{n \times m}$ satisfies $\left(Q_{k}^{p}\right)^{T} Q_{k}^{p}=I$ and $R_{k}^{p} \in \mathfrak{R}^{m \times m}$ is an upper triangle matrix. Then, we solve the linear system (22) as follows:

$$
\begin{equation*}
\left(R_{k}^{p}\right)^{T} d_{k}^{c}=-c\left(x_{k+1}^{p}\right), s_{k}^{c}=Q_{k}^{p} d_{k}^{c}, x_{k+1}=x_{k+1}^{p}+s_{k}^{c} . \tag{23}
\end{equation*}
$$

We define the quadratic model $q_{k}(s)$ as follows:

$$
\begin{equation*}
q_{k}(s)=f\left(x_{k}\right)+s^{T} g_{k}+\frac{1}{2} s^{T} B_{k} s, \tag{24}
\end{equation*}
$$

where $g_{k}=\nabla f\left(x_{k}\right)$ and $B_{k}=P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ or its quasi-Newton approximation. Similarly to the trust-region subproblem of the null space method (pp. 571-574, [79]), we decompose the predicted reduction into two parts:

$$
\begin{equation*}
\operatorname{Hpred}_{k}=q_{k}(0)-q_{k}\left(s_{k}^{p}\right), \operatorname{Vpred}_{k}=q_{k}\left(s_{k}^{p}\right)-q_{k}\left(s_{k}^{p}+s_{k}^{c}\right) . \tag{25}
\end{equation*}
$$

Thus, in order to ensure the global convergence of the regularization continuation method (18)-(23), the accepted prediction step $s_{k}^{p}$ and the correction step $s_{k}^{c}$ need to satisfy the following condition:

$$
\begin{equation*}
\left\|s_{k}^{c}\right\| \leq \theta_{1}\left\|s_{k}^{p}\right\|, \tag{26}
\end{equation*}
$$

where $\theta_{1}$ is a large positive constant such as $10^{6}$.
Remark 4 The time step $\Delta t_{k}$ of the regularization continuation method (18)-(22) is not restricted by the numerical stability. Therefore, the large time step $\Delta t_{k}$ can be adopted in the steady-state phase such that the regularization continuation method (18)-(22) mimics the projected Newton method near the stationary point $x^{*}$ and it has the fast rate of convergence. The most of all, the new step $\alpha_{k}=\Delta t_{k} /\left(\Delta t_{k}+1\right)$ is favourable to adopt the trust-region updating strategy for adjusting the time step $\Delta t_{k}$. Consequently, the regularization continuation method (18)-(22) accurately follows the trajectory of the regularization flow (15) in the transient-state phase and achieves the fast rate of convergence near the stationary point $x^{*}$.

### 2.3 The adaptive step control

Another issue is how to adaptively adjust the time step $\Delta t_{k}$ at every iteration. We borrow the adjustment technique of the trust-region method due to its robustness and its fast rate of convergence $[13,88]$. According to the structure-preserving property of the regularization continuation method (18)-(22), $x_{k+1}$ will be expected to preserve the feasibility by computing the correction step $s_{k}^{c}$ of equation (23). That is to say, $x_{k+1}$ satisfies $c\left(x_{k+1}\right) \approx 0$. Therefore, we use the objective function $f(x)$ instead of the nonsmooth penalty function $f(x)+\sigma \|\left. c(x)\right|_{1}$ as the merit function. Similarly to the stepping-time scheme of the ODE method for the unconstrained optimization problem $[34,45,52]$ and the linearly constrained optimization problem [49,54], we also need to construct a local approximation model of $f(x)$ around $x_{k}$. Here, we adopt the quadratic function defined by equation (24) as its approximation model.

We define the ratio of the actual reduction Ared $_{k}$ to the predicted reduction Pred $_{k}$ as follows:

$$
\begin{equation*}
\operatorname{Ared}_{k} \triangleq f\left(x_{k}\right)-f\left(x_{k}+s_{k}\right), \operatorname{Pred}_{k} \triangleq q_{k}(0)-q_{k}\left(s_{k}\right), \rho_{k}=\frac{\text { Ared }_{k}}{\text { Pred }_{k}} \tag{27}
\end{equation*}
$$

Thus, we accept the trial step $s_{k}$ and let $x_{k+1}=x_{k}+s_{k}$, when $\rho_{k} \geq \eta_{a},\left\|c\left(x_{k}+s_{k}\right)\right\|_{\infty} \leq$ $\varepsilon_{0}$ and the predicted reduction $\operatorname{Pred}_{k}=q_{k}(0)-q_{k}\left(s_{k}\right)$ satisfies the Armijo sufficient descent condition:

$$
\begin{equation*}
\operatorname{Pred}_{k} \geq \eta_{q}\left\|s_{k}^{p}\right\|\left\|p_{g_{k}}\right\|, \tag{28}
\end{equation*}
$$

where $p_{g_{k}}=P\left(x_{k}\right) g\left(x_{k}\right)=P\left(x_{k}\right) \nabla f\left(x_{k}\right)$ and $s_{k}^{p}$ is computed by equation (18), and $\eta_{a}, \eta_{q}$ are the small positive constants such as $\eta_{a}=\eta_{q}=10^{-6}$, and $\varepsilon_{0}$ is less than the tolerance error $\varepsilon$ such as $\varepsilon_{0}=\frac{1}{10} \varepsilon$ and $\varepsilon=10^{-6}$. Otherwise, we discard it and let $x_{k+1}=x_{k}$.

Consequently, we reduce or enlarged the time step $\Delta t_{k+1}$ at every iteration according to the ratio $\rho_{k}$ defined by equation (27). A particular adjustment strategy is given as follows:

$$
\Delta t_{k+1}=\left\{\begin{array}{l}
\left.\gamma_{1} \Delta t_{k}, \text { if (the trial step } s_{k} \text { is accepted and } \rho_{k} \geq \eta_{2}\right),  \tag{29}\\
\left.\Delta t_{k}, \text { else if (the trial step } s_{k} \text { is accepted and } \eta_{1}<\rho_{k}<\eta_{2}\right), \\
\gamma_{2} \Delta t_{k}, \text { others, }
\end{array}\right.
$$

where the constants are selected as $\eta_{1}=0.25, \gamma_{1}=2, \eta_{2}=0.75, \gamma_{2}=0.5$ according to our numerical experiments.

Remark 5 This new time-stepping scheme based on the trust-region updating strategy has some advantages compared to the traditional line search strategy [44]. If we use the line search strategy and the damped projection Newton method (16)-(17) to follow the trajectory $x(t)$ of the projected Newton flow (15), in order to achieve the fast rate of convergence in the steady-state phase, the time step $\alpha_{k}$ of the damped projection Newton method is tried from 1 and reduced by half with many times at every iteration. Since the quadratic model $f\left(x_{k}\right)+\nabla f\left(x_{k}\right)^{T} s_{k}+\frac{1}{2} s_{k}^{T} B_{k} s_{k}$ may not approximate $f\left(x_{k}+\right.$ $s_{k}$ ) well in the transient-state phase, the time step $\alpha_{k}$ will be small. Consequently, the line search strategy consumes the unnecessary trial steps in the transient-state phase. However, the selection scheme of the time step based on the trust-region strategy (27)-(29) can overcome this shortcoming.

### 2.4 The adaptively preconditioned technique

For the large-scale problem, the numerical evaluation of the two-sided projection matrix $P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ consumes much time. In order to overcome this shortcoming, in the well-posed phase, we use the Broyden-Fletcher-Goldfarb-Shanno (BFGS) quasi-Newton matrix (see [5,18,25,58,76] or pp. 222-230, [65]) to approximate the two-sided projection matrix $P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ of the regularization continuation method (18)-(23) as follows:

$$
B_{k+1}=\left\{\begin{array}{l}
B_{k}+\frac{y_{k} y_{k}^{T}}{y_{k}^{T} s_{k}}-\frac{B_{k} s_{k} s_{k}^{T} B_{k}}{s_{k}^{T} B_{k} s_{k}}, \text { if } y_{k}^{T} s_{k}>0,  \tag{30}\\
B_{k}, \text { otherwise },
\end{array}\right.
$$

where $y_{k}=P\left(x_{k+1}\right) g\left(x_{k+1}\right)-P\left(x_{k}\right) g\left(x_{k}\right), s_{k}=x_{k+1}-x_{k}$ and $B_{0}=I$.
The BFGS updating matrix $B_{k}$ has some nice properties. For example, $B_{k+1}$ is symmetric positive definite when $B_{k}$ is symmetric positive definite and $B_{k+1}$ is updated by the BFGS formula (30) (p. 199, [65]). For the large-scale problem, it consumes much time to solve the large-scale system (18) of linear equations. In order
to save the computational time of solving linear equations, we obtain the inverse $\left(\sigma_{k} I+B_{k}\right)^{-1}$ of the regularization matrix $\left(\sigma_{k} I+B_{k}\right)$ by using the following Sherman-Morrison-Woodbury formula (p. 17, [79]):

$$
\begin{equation*}
\left(B+S V^{T}\right)^{-1}=B^{-1}-B^{-1} S\left(I+V^{T} B^{-1} S\right)^{-1} V^{T} B^{-1} \tag{31}
\end{equation*}
$$

where $B$ is an $n \times n$ nonsingular matrix and $S, V$ are two $p \times n$ matrices. Generally speaking, $p$ is less more than $n$. We denote matrices $S_{k}$ and $V_{k}$ as follows:

$$
\begin{align*}
& S_{k}=\left\{\begin{array}{l}
{\left[S_{k-1}, \frac{y_{k}}{\left(s_{k}^{T} y_{k}\right)^{1 / 2}}, \frac{m_{k}}{\left(s_{k}^{T} m_{k}\right)^{1 / 2}}\right], \text { if } y_{k}^{T} s_{k}>0,} \\
{\left[S_{k-1}, 0,0\right], \text { otherwise }}
\end{array}\right.  \tag{32}\\
& V_{k}=\left\{\begin{array}{l}
{\left[V_{k-1}, \frac{y_{k}}{\left(s_{k}^{T} y_{k}\right)^{1 / 2}},-\frac{m_{k}}{\left(s_{k}^{T} m_{k}\right)^{1 / 2}}\right], \text { if } y_{k}^{T} s_{k}>0,} \\
{\left[V_{k-1}, 0,0\right], \text { otherwise, }}
\end{array}\right. \tag{33}
\end{align*}
$$

where $m_{k}=B_{k} s_{k}=s_{k}+S_{k-1}\left(V_{k-1}^{T} s_{k}\right)$. Then, from equations (32)-(33), the BFGS quasi-Newton formula (30) can be written as

$$
\begin{equation*}
B_{k+1}=I+S_{k} V_{k}^{T} . \tag{34}
\end{equation*}
$$

By using the Sherman-Morrison-Woodbury formula (31), from equation (34), we obtain

$$
\begin{equation*}
\left(\sigma_{k} I+B_{k}\right)^{-1}=\frac{1}{1+\sigma_{k}}\left(I-S_{k-1}\left(\left(1+\sigma_{k}\right) I+V_{k-1}^{T} S_{k-1}\right)^{-1} V_{k-1}^{T}\right) \tag{35}
\end{equation*}
$$

Remark 6 It is worthwhile to discuss whether matrix $I+V^{T} B^{-1} S$ in equation (31) is nonsingular or not. Actually, when matrix $B$ is symmetric positive definite and matrix $B+S V^{T}$ is positive definite (that is to say, all eigenvalues of $B+S V^{T}$ are greater than 0 ), $I+V^{T} B^{-1} S$ is nonsingular.

Proof. Since $B$ is symmetric positive definite, it can be decomposed as $B=L L^{T}$ by the Cholesky factorization (p. 163, [27]), where $L$ is a nonsingular matrix. Thus, we have $B+S V^{T}=L\left(I+\left(L^{-1} S\right)\left(V^{T} L^{-T}\right)\right) L^{T}$. By combining the positive definiteness of $B+S V^{T}$, we know that $I+\left(L^{-1} S\right)\left(V^{T} L^{-T}\right)$ is positive definite. Therefore, all eigenvalues of $\left(L^{-1} S\right)\left(V^{T} L^{-T}\right)$ are greater than -1 . Furthermore, the eigenvalues of $\left(L^{-1} S\right)\left(V^{T} L^{-T}\right)$ equal those of $\left(V^{T} L^{-T}\right)\left(L^{-1} S\right)$ except for their zero eigenvalues. Consequently, all eigenvalues of $\left(V^{T} L^{-T}\right)\left(L^{-1} S\right)$ are greater than -1 . Namely, all eigenvalues of $V^{T} B^{-1} S$ are greater than -1. Therefore, $I+V^{T} B^{-1} S$ is a nonsingular matrix.

According to our numerical experiments [49,54], the regularization continuation method (18)-(23) with the BFGS updating formula (32)-(35) works well for most problems and the objective function decreases very fast in the well-posed phase. However, for the ill-posed problems, the regularization continuation method (18)(23) with the BFGS updating formula (32)-(35) will approach the stationary solution
$x^{*}$ very slow in the ill-posed phase. Furthermore, it fails to get close to the stationary solution $x^{*}$ sometimes.

In order to improve the robustness of the regularization continuation method (18)(23), we set $B_{k}=P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ in the ill-posed phase. Now, the problem is how to automatically identify the ill-posed phase and switch to $B_{k}=P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ from the BFGS updating formula (30). Here, we adopt the simple criterion. That is to say, we regard that the regularization continuation method (18)-(23) is in the ill-posed phase once there exists the time step $\Delta t_{K} \leq 10^{-3}$.

In the ill-posed phase, the computational time of the projected Hessian matrix $P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ is heavy if we update it at every iteration. In order to save the computational time of the Hessian evaluation $\nabla^{2} f\left(x_{k}\right)$, we set $B_{k+1}=B_{k}$ when $q_{k}(0)-$ $q_{k}\left(s_{k}\right)$ approximates $f\left(x_{k}\right)-f\left(x_{k}+s_{k}\right)$ well, where the approximation model $q_{k}(s)$ is defined by equation (24). Otherwise, we update $B_{k+1}=P\left(x_{k+1}\right) \nabla^{2} f\left(x_{k+1}\right) P\left(x_{k+1}\right)$ in the ill-posed phase [53,54]. In the ill-posed phase, a practice updating strategy is give by

$$
B_{k+1}=\left\{\begin{array}{l}
B_{k}, \text { if }\left|1-\rho_{k}\right| \leq \eta_{1}  \tag{36}\\
P\left(x_{k+1}\right) \nabla^{2} f\left(x_{k+1}\right) P\left(x_{k+1}\right), \text { otherwise }
\end{array}\right.
$$

where $\rho_{k}$ is defined by equations (24)-(27) and $\eta_{1}=0.25$.

### 2.5 Finding an initial feasible point

For the regularization continuation method based on the ODE system (15), one of the important issues is how to find an initial feasible point $x_{0}$. That is to say, the initial point $x_{0}$ needs to satisfy $c\left(x_{0}\right)=0$. Here, we use the generalized continuation Newton method [53] to solve the under-determined system $c(x)=0$ due to its robustness and efficiency. For convenience, we give the rough description of the generalized continuation Newton method. Its detailed description and its convergence analysis can be found in reference [53].

For the under-determined system $c(z)=0$, we construct the generalized Newton flow

$$
\begin{equation*}
\frac{d z(\tau)}{d \tau}=-A(z)^{\dagger} c(z), z\left(\tau_{0}\right)=z_{0} \tag{37}
\end{equation*}
$$

where $A(z)^{\dagger}$ is the Moore-Penrose generalized inverse of the Jacobian matrix $A(z)$ (p. 11, [79] or p. 290, [27]). Then, we construct the generalized continuation Newton method [53] to follow the generalized Newton flow (37) and obtain its steady-state solution $z^{*}$ as follows:

$$
\begin{equation*}
\Delta z_{j}=-\frac{\Delta \tau_{j}}{1+\Delta \tau_{j}} A_{j}^{\dagger} c\left(z_{j}\right), z_{j+1}=z_{j}+\Delta z_{j} \tag{38}
\end{equation*}
$$

where $A_{j}$ equals $A\left(x_{j}\right)$ or its approximation according to the following ratio

$$
\begin{equation*}
r_{j}=\frac{\left\|c\left(z_{j}\right)\right\|-\left\|c\left(z_{j}+\Delta z_{j}\right)\right\|}{\left\|c\left(z_{j}\right)\right\|-\left\|c\left(z_{j}\right)+A_{j} \Delta z_{j}\right\|}=\frac{\left\|c\left(z_{j}\right)\right\|-\left\|c\left(z_{j}+\Delta z_{j}\right)\right\|}{\left(\Delta \tau_{j} /\left(1+\Delta \tau_{j}\right)\right)\left\|c\left(z_{j}\right)\right\|} \tag{39}
\end{equation*}
$$

In other words, we update the Jacobian matrix $A_{j+1}$ according to the following strategy:

$$
A_{j+1}=\left\{\begin{array}{l}
A_{j}, \text { if }\left|1-r_{j}\right| \leq \eta_{1}  \tag{40}\\
A\left(z_{j+1}\right), \text { otherwise }
\end{array}\right.
$$

For a real-world problem, $A_{j} A_{j}^{T}$ may be ill-conditioned. Thus, the Cholesky decomposition may fail to solve the linear system (38) for the large-scale problem. In order to improve its robustness, we use the QR decomposition to solve it as follows:

$$
\begin{equation*}
A_{j}^{T}=U_{j} W_{j}, W_{j}^{T} \Delta z_{j}^{m}=-c\left(z_{j}\right), \Delta z_{j}^{N}=U_{j} \Delta z_{j}^{m}, \Delta z_{j}=\frac{\Delta \tau_{j}}{1+\Delta \tau_{j}} \Delta z_{j}^{N} \tag{41}
\end{equation*}
$$

where $U_{j} \in \mathfrak{R}^{n \times m}$ satisfies $U_{j}^{T} U_{j}=I$ and $W_{j} \in \mathfrak{R}^{m \times m}$ is an upper triangle matrix. In practice, in order to save the computational time of decomposing the matrix $A_{j+1}$ when $A_{j}$ performs well, i.e. $\left|1-r_{j}\right| \leq \eta_{1}$, according to the updating formula (40), we set $W_{j+1}=W_{j}$ and $U_{j+1}=U_{j}$ in equation (41).

The adaptive time step $\Delta \tau_{j}$ of the generalized continuation Newton method (38) is adjusted by the following trust-region updating strategy:

$$
\Delta \tau_{j+1}= \begin{cases}\gamma_{1} \Delta \tau_{j}, & \text { if }\left|1-r_{j}\right| \leq \eta_{1}  \tag{42}\\ \Delta \tau_{j}, & \text { else if } \eta_{1}<\left|1-r_{j}\right|<\eta_{2} \\ \gamma_{2} \Delta \tau_{j}, & \text { others }\end{cases}
$$

where the constants are selected as $\gamma_{1}=2, \gamma_{2}=0.5, \eta_{1}=0.25, \eta_{2}=0.75$, according to our numerical experiments.

For a real-world problem, the analytical Jacobian $A\left(z_{j}\right)$ may not be offered. Thus, in practice, we replace the Jacobian matrix $A\left(z_{j}\right)$ with its difference approximation as follows:

$$
\begin{equation*}
A\left(z_{k}\right) \approx\left[\frac{c\left(z_{j}+\varepsilon e_{1}\right)-c\left(z_{j}\right)}{\varepsilon}, \ldots, \frac{c\left(z_{j}+\varepsilon e_{n}\right)-c\left(z_{j}\right)}{\varepsilon}\right] \tag{43}
\end{equation*}
$$

where the elements of $e_{i}$ equal zeros except for the $i$-th element which equals 1 , and the parameter $\varepsilon$ can be selected as $10^{-6}$ according to our numerical experiments.

According to the above descriptions, we give the detailed implementation of the generalized continuation Newton method with the trust-region updating strategy (GCNMtr) to find an initial feasible point $z^{*}$ of $c(z)=0$ in Algorithm 1.

By combining the discussions of the previous sections and Algorithm 1, we give the detailed implementation of the regularization continuation method and the trustregion updating strategy for the optimization problem (1) with nonlinear equality constraints in Algorithm 2.

```
Algorithm 1 Generalized continuation Newton methods and the trust-region updat-
ing strategy for the under-determined system (The GCNMTr method)
Input:
    Function \(c: \mathfrak{K}^{n} \rightarrow \mathfrak{R}^{m}, m \leq n\), the initial point \(z_{0}\) (optional), and the tolerance \(\varepsilon\) (optional).
Output:
    An approximation solution \(z^{*}\) of nonlinear equations.
    Set the default \(z_{0}=\operatorname{ones}(n, 1)\) and \(\varepsilon=10^{-7}\), when \(z_{0}\) or \(\varepsilon\) is not provided.
    Initialize the parameters: \(\eta_{a}=10^{-6}, \eta_{1}=0.25, \gamma_{1}=2, \eta_{2}=0.75, \gamma_{2}=0.5\), maxit \(=400\).
    Set \(\Delta \tau_{0}=10^{-2}\), flag_success_trialstep \(=1\), itc \(=0, j=0\).
    Evaluate \(c_{j}=c\left(z_{j}\right)\).
    Set \(r_{j-1}=0\).
    while (itc \(<\) maxit) do
        if (flag_success_trialstep \(==1\) ) then
            Set itc \(=i t c+1\).
            Compute \(\operatorname{Res}_{j}=\left\|c_{j}\right\|_{\infty}\).
            if \(\left(\operatorname{Res}_{j}<\varepsilon\right)\) then
                break;
            end if
            if \(\left(\left|1-r_{j-1}\right|>\eta_{1}\right)\) then
                Evaluate \(A_{j}=A\left(z_{j}\right)\) from equation (43).
                    Use the QR decomposition \(\left[\bar{U}_{j}, \bar{W}_{j}\right]=\operatorname{qr}\left(A_{j}^{T}\right)\) and set \(U_{j}=\bar{U}_{j}(:, 1: m), W_{j}=\bar{W}_{j}(1: m, 1: m)\).
            else
            Set \(U_{j}=U_{j-1}, W_{j}=W_{j-1}\).
            end if
            By solving \(W_{j}^{T} \Delta z_{j}^{m}=-c_{j}\) and \(\Delta z_{j}^{N}=U_{j} \Delta z_{j}^{m}\), we obtain the Newton step \(\Delta z_{j}^{N}\).
        end if
        Set \(\Delta z_{j}=\Delta \tau_{j} /\left(1+\Delta \tau_{j}\right) \Delta z_{j}^{N}, z_{j+1}=z_{j}+\Delta z_{j}\).
        Evaluate \(c_{j+1}=c\left(z_{j+1}\right)\).
        if \(\left(\left\|c_{j}\right\|<\left\|c_{j+1}\right\|\right)\) then
            Set \(r_{j}=-1\);
        else
            Compute the ratio \(r_{j}\) from equation (39).
        end if
        Adjust the time step size \(\Delta \tau_{j+1}\) according to the trust-region updating strategy (42).
        if \(\left(r_{j} \geq \eta_{a}\right)\) then
            Accept the trial point \(z_{j+1}\). Set flag_success_trialstep \(=1\).
        else
            Set \(z_{j+1}=z_{j}, c_{j+1}=c_{j}, \Delta z_{j+1}^{N}=\Delta z_{j}^{N}\), flag_success_trialstep \(=0\).
        end if
        Set \(j \longleftarrow j+1\).
    end while
```

## 3 Algorithm Analysis

In this section, we analyze the global convergence of the regularization continuation method (18)-(23) and the adaptive time step control for the nonlinearly equalityconstrained optimization problem (i.e. Algorithm 2). Similarly to the result of the trust-region method for the unconstrained optimization problem [69] and the continuation method for linearly constrained optimization problem [49], we have the following lower bound estimation of $q_{k}(0)-q_{k}\left(s_{k}^{p}\right)$.

Lemma 1 Assume that the quadratic model $q_{k}(s)$ is defined by equation (24) and $d_{k}$ is the solution of equation (18). Furthermore, we suppose that the time step $\Delta t_{k}$

```
Algorithm 2 The regularization continuation method for optimization problems with
nonlinear equality constraints (the Rcm method)
Input: the objective function \(f: \mathfrak{R}^{n} \rightarrow \mathfrak{R}\), the equality constraints \(c(x)=0, c: \mathfrak{R}^{n} \rightarrow \mathfrak{R}^{m}\), the initial
    point \(z_{0}\) (optional), the terminated parameter \(\varepsilon\) (optional).
Output: the optimal approximation solution \(x^{*}\).
    If \(z_{0}\) or \(\varepsilon\) is not provided, we set \(z_{0}=\) ones \((n, 1)\) or \(\varepsilon=10^{-6}\). We let \(\varepsilon_{0}=\frac{1}{10} \varepsilon\).
    Initialize parameters: \(\eta_{a}=10^{-6}, \eta_{m}=10^{-6}, \eta_{1}=0.25, \gamma_{1}=2, \eta_{2}=0.75, \gamma_{2}=0.5, \sigma_{0}=\)
    \(10^{-5}, \Delta t_{K}=10^{-3}\), max_itc \(=300\). Set \(\Delta t_{0}=10^{-2}\), flag_illposed_phase \(=0\), flag_success_trialstep \(=1\),
    \(s_{-1}=0, y_{-1}=0, \rho_{-1}=0, B_{0}=I, H_{0}=I, Q_{-1}^{b}=I, R_{-1}^{b}=I, S_{-1}=\operatorname{zeros}(n, 1), V_{-1}=\operatorname{zeros}(n, 1)\),
    itc \(=0\).
3: Use the generalized continuation Newton method (the GCNMTr method, Algorithm 1) to find an
    initial feasible point from \(z_{0}\) and denote this initial feasible point as \(x_{0}\).
    Set \(k=0\). Evaluate \(f_{0}=f\left(x_{0}\right)\) and \(g_{0}=\nabla f\left(x_{0}\right)\). Evaluate \(A_{0}=A\left(x_{0}\right)\) from equation (43).
    Factorize \(A_{0}^{T}\) by the QR decomposition \(\left[\bar{Q}_{0}, \bar{R}_{0}\right]=\operatorname{qr}\left(A_{0}^{T}\right)\).
    Set \(Q_{0}=\bar{Q}_{0}(:, 1: m), R_{0}=\bar{R}_{0}(1: m, 1: m)\).
    Compute the projected gradient \(p_{g_{0}}=P_{0} g_{0}\), where \(P_{0}\) is computed by equation (21).
    while \(\left(\left(\left\|p_{g_{k}}\right\|_{\infty}>\varepsilon\right)\right.\) and (itc \(<\) max_itc \(\left.)\right)\) do
        itc \(=\) itc +1 ;
        if \(\Delta t_{k}<\Delta t_{K}\) then
            Set flag_illposed_phase \(=1\).
        end if
        if (flag_illposed_phase \(==0\) ) then
            if (flag_success_trialstep \(==1\) ) then
                if \(k>0\) then
                            Solve equations (32)-(33) to obtain matrices \(S_{k-1}\) and \(V_{k-1}\).
                else
                    Set \(S_{-1}=\operatorname{zeros}(n, 1)\) and \(V_{-1}=\operatorname{zeros}(n, 1)\).
                end if
                Solve equations (18) and (35) to obtain
                \(d_{k}=-\left(\left(p_{g_{k}}-S_{k-1}\left(\left(\left(1+\sigma_{0} / \Delta t_{k}\right) I+V_{k-1}^{T} S_{k-1}\right)^{-1}\left(V_{k-1}^{T} p_{g_{k}}\right)\right)\right)\right) /\left(1+\sigma_{0} / \Delta t_{k}\right)\).
            end if
        else
            if \(\left(\left|\rho_{k-1}-1\right|>\eta_{1}\right)\) then
                Evaluate \(H_{k}=P_{k} \nabla^{2} f\left(x_{k}\right) P_{k}\) from equation (115).
                Set \(B_{k}=\left(\sigma_{0} / \Delta t_{k}\right) I+H_{k}\) and use the QR decomposition \(B_{k}=Q_{k}^{b} R_{k}^{b}\).
            else
                \(Q_{k}^{b}=Q_{k-1}^{b}, R_{k}^{b}=R_{k-1}^{b} ;\)
            end if
            Solve the linear system \(R_{k}^{b} d_{k}=-\left(Q_{k}^{b}\right)^{T} p_{g_{k}}\) to obtain \(d_{k}\).
        end if
        Set \(s_{k}^{p}=\frac{\Delta t_{k}}{1+\Delta t_{k}}\left(P_{k} d_{k}\right)\) and \(x_{k+1}^{p}=x_{k}+s_{k}^{p}\). Evaluate \(c_{k+1}^{p}=c\left(x_{k+1}^{p}\right)\).
        Solve the linear systems \(\left(R_{k}\right)^{T} d_{k}^{c}=-c_{k+1}^{p}, s_{k}^{c}=Q_{k} d_{k}^{c}\).
        Set \(x_{k+1}=x_{k+1}^{p}+s_{k}^{c}, c_{k+1}=c\left(x_{k+1}\right)\).
        if \(\left(\left\|c_{k+1}\right\|_{\infty}>\varepsilon_{0}\right)\) then
            Evaluate \(A_{k+1}^{p}=A\left(x_{k+1}^{p}\right)\) from equation (43).
            Solve the linear system (23) to obtain \(x_{k+1}\) and evaluate \(c_{k+1}=c\left(x_{k+1}\right)\).
        end if
        Evaluate \(f_{k+1}=f\left(x_{k+1}\right)\) and compute the ratio \(\rho_{k}\) from equations (24)-(27).
        if ( \(\rho_{k} \geq \eta_{a},\left\|c_{k+1}\right\|_{\infty} \leq \varepsilon_{0}\) and \(s_{k}\) satisfies the sufficient descent condition (28)) then
            Set flag_success_trialstep \(=1\). Evaluate \(g_{k+1}=\nabla f\left(x_{k+1}\right)\).
            Evaluate \(A_{k+1}=A\left(x_{k+1}\right)\) from equation (43).
            Factorize \(A_{k+1}^{T}\) by the QR decomposition \(\left[\bar{Q}_{k+1}, \bar{R}_{k+1}\right]=\operatorname{qr}\left(A_{k+1}^{T}\right)\).
            Set \(Q_{k+1}=\bar{Q}_{k+1}(:, 1: m), R_{k+1}=\bar{R}_{k+1}(1: m, 1: m)\).
            Set \(p_{g_{k+1}}=P_{k+1} g_{k+1}\), where \(P_{k+1}\) is computed by equation (21).
            Set \(s_{k}=x_{k+1}-x_{k}\) and \(y_{k}=p_{g_{k+1}}-p_{g_{k}}\).
        else
            Set flag_success_trialstep \(=0\).
            \(x_{k+1}=x_{k}, f_{k+1}=f_{k}, p_{g_{k+1}}=p_{g_{k}}, g_{k+1}=g_{k}, H_{k+1}=H_{k}, d_{k+1}=d_{k}\).
        end if
        Adjust the time step \(\Delta t_{k+1}\) based on the trust-region updating strategy (29).
        Set \(k \leftarrow k+1\).
    end while
```

satisfies

$$
\begin{equation*}
\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right) \succ 0 \text { and }\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}-P_{k}^{T} B_{k} P_{k}\right) \succeq 0 \tag{44}
\end{equation*}
$$

where $P_{k}=P\left(x_{k}\right)$ is the projection matrix defined by equation (10). Then, we have

$$
\begin{equation*}
q_{k}(0)-q_{k}\left(P_{k} d_{k}\right) \geq \frac{1}{2}\left\|p_{g_{k}}\right\| \min \left\{\left\|P_{k} d_{k}\right\|, \frac{\left\|p_{g_{k}}\right\|}{3\left\|B_{k}\right\|}\right\} \tag{45}
\end{equation*}
$$

where $p_{g_{k}}=P_{k} g_{k}$.
Proof. Let $\tau_{k}=\sigma_{0} / \Delta t_{k}$. From equation (18), we obtain

$$
\begin{align*}
q_{k}(0) & -q_{k}\left(P_{k} d_{k}\right)=-\frac{1}{2}\left(d_{k}^{T} P_{k}^{T} B_{k} P_{k} d_{k}\right)-\left(P_{k} g_{k}\right)^{T} d_{k} \\
& =-\frac{1}{2}\left(d_{k}^{T} P_{k}^{T} B_{k} P_{k} d_{k}\right)+p_{g_{k}}^{T}\left(\tau_{k} I+B_{k}\right)^{-1} p_{g_{k}} \\
& =\frac{1}{2}\left(p_{g_{k}}^{T}\left(\tau_{k} I+B_{k}\right)^{-1} p_{g_{k}}+d_{k}^{T}\left(-P_{k}^{T} B_{k} P_{k}+\tau_{k} I+B_{k}\right) d_{k}\right) . \tag{46}
\end{align*}
$$

We denote $\mu_{\min }\left(B_{k}-P_{k}^{T} B_{k} P_{k}\right)$ as the smallest eigenvalue of matrix $\left(B_{k}-P_{k}^{T} B_{k} P_{k}\right)$, and set

$$
\begin{equation*}
\tau_{l b}=\min \left\{0, \mu_{\min }\left(B_{k}-P_{k}^{T} B_{k} P_{k}\right)\right\} \tag{47}
\end{equation*}
$$

From equations (44), (46)-(47) and the bound on the eigenvalues of matrix ( $\tau_{k} I+$ $\left.B_{k}\right)^{-1}$, we obtain

$$
\begin{align*}
& q_{k}(0)-q_{k}\left(P_{k} d_{k}\right) \geq \frac{1}{2}\left(p_{g_{k}}^{T}\left(\tau_{k} I+B_{k}\right)^{-1} p_{g_{k}}+\left(\tau_{k}+\tau_{l b}\right)\left\|d_{k}\right\|^{2}\right) \\
& \quad \geq \frac{1}{2}\left(\frac{\left\|p_{g_{k}}\right\|^{2}}{\tau_{k}+\left\|B_{k}\right\|}+\left(\tau_{k}+\tau_{l b}\right)\left\|d_{k}\right\|^{2}\right) \tag{48}
\end{align*}
$$

In the above second inequality, we use the property $\left|\mu_{i}\left(B_{k}\right)\right| \leq\left\|B_{k}\right\|$, where $\mu_{i}\left(B_{k}\right)$ is an eigenvalue of matrix $B_{k}$.

Now we consider the properties of the function

$$
\begin{equation*}
\varphi(\tau) \triangleq \tau\left\|d_{k}\right\|^{2}+\left\|p_{g_{k}}\right\|^{2} /\left(\tau-\tau_{l b}+\left\|B_{k}\right\|\right) . \tag{49}
\end{equation*}
$$

From equation (49), we have $\varphi^{\prime \prime}(\tau)=2\left\|p_{g_{k}}\right\|^{2} /\left(\tau-\tau_{l b}+\left\|B_{k}\right\|\right)^{3} \geq 0$ when $\left(\tau-\tau_{l b}\right.$ $\left.+\left\|B_{k}\right\|\right)>0$. Thus, the function $\varphi(\tau)$ attains its minimum $\varphi\left(\tau_{\min }\right)$ when $\tau_{\min }$ satisfies $\varphi^{\prime}\left(\tau_{\min }\right)=0$ and $\tau \geq-\left(-\tau_{l b}+\left\|B_{k}\right\|\right)$. Namely, we have

$$
\begin{equation*}
\varphi\left(\tau_{\min }\right)=2\left\|p_{g_{k}}\right\|\left\|d_{k}\right\|+\left(\tau_{l b}-\left\|B_{k}\right\|\right)\left\|d_{k}\right\|^{2} \tag{50}
\end{equation*}
$$

where

$$
\begin{equation*}
\tau_{\min }=\frac{\left\|p_{g_{k}}\right\|}{\left\|d_{k}\right\|}+\tau_{l b}-\left\|B_{k}\right\| . \tag{51}
\end{equation*}
$$

We prove the property (45) via separately considering $\tau_{\min } \geq 0$ or $\tau_{\min }<0$ as follows.
(i) When $\left(\left\|p_{g_{k}}\right\| /\left\|d_{k}\right\|+\left(\tau_{l b}-\left\|B_{k}\right\|\right)\right) \geq 0$, from equation (51), we have $\tau_{\min } \geq 0$. From the assumption (44) and the definition (47) of $\tau_{l b}$, we have $\tau_{k} \geq-\tau_{l b}$. Thus, from equations (48)-(51), we obtain

$$
\begin{gather*}
q_{k}(0)-q_{k}\left(P_{k} d_{k}\right) \geq \frac{1}{2}\left(\left(\tau_{k}+\tau_{l b}\right)\left\|d_{k}\right\|^{2}+\frac{\left\|p_{g_{k}}\right\|^{2}}{\tau_{k}+\left\|B_{k}\right\|}\right)=\frac{1}{2} \varphi\left(\tau_{k}+\tau_{l b}\right) \geq \frac{1}{2} \varphi\left(\tau_{\min }\right) \\
=\frac{1}{2}\left(\left\|p_{g_{k}}\right\|\left\|d_{k}\right\|+\left(\left\|p_{g_{k}}\right\|\left\|d_{k}\right\|+\left(\tau_{l b}-\left\|B_{k}\right\|\right)\left\|d_{k}\right\|^{2}\right)\right) \geq \frac{1}{2}\left\|p_{g_{k}}\right\|\left\|d_{k}\right\| \tag{52}
\end{gather*}
$$

(ii) The other case is $\left(\left\|p_{g_{k}}\right\| /\left\|d_{k}\right\|+\left(\tau_{l b}-\left\|B_{k}\right\|\right)\right)<0$. In this case, from equation (51), we have $\tau_{\min }<0$. It is not difficult to verify that $\varphi(\tau)$ is monotonically increasing when $\tau \geq 0$ and $\tau_{\min }<0$. From the definition (47) of $\tau_{l b}$ and the property (11), we have

$$
\begin{aligned}
\left|\tau_{l b}\right| & \leq\left|\mu_{\min }\left(B_{k}-P_{k}^{T} B_{k} P_{k}\right)\right| \leq\left\|B_{k}-P_{k}^{T} B_{k} P_{k}\right\| \leq\left\|B_{k}\right\|+\left\|P_{k}^{T} B_{k} P_{k}\right\| \\
& \leq\left\|B_{k}\right\|+\left\|P_{k}^{T}\right\|\left\|B_{k}\right\|\left\|P_{k}\right\|=2\left\|B_{k}\right\| .
\end{aligned}
$$

By using this property and the monotonicity of $\varphi(\tau)$, from equations (48)-(49), we obtain

$$
\begin{align*}
& q_{k}(0)-q_{k}\left(P_{k} d_{k}\right) \geq \frac{1}{2}\left(\left(\tau_{k}+\tau_{l b}\right)\left\|d_{k}\right\|^{2}+\frac{\left\|p_{g_{k}}\right\|^{2}}{\tau_{k}+\left\|B_{k}\right\|}\right) \\
& =\frac{1}{2} \varphi\left(\tau_{k}+\tau_{l b}\right) \geq \frac{1}{2} \varphi(0)=\frac{1}{2\left(-\tau_{l b}+\left\|B_{k}\right\|\right)}\left\|p_{g_{k}}\right\|^{2} \geq \frac{1}{6\left\|B_{k}\right\|}\left\|p_{g_{k}}\right\|^{2} . \tag{53}
\end{align*}
$$

From equations (52)-(53), we get

$$
\begin{equation*}
q_{k}(0)-q_{k}\left(P_{k} d_{k}\right) \geq \frac{1}{2}\left\|p_{g_{k}}\right\| \min \left\{\left\|d_{k}\right\|, \frac{\left\|p_{g_{k}}\right\|}{3\left\|B_{k}\right\|}\right\} . \tag{54}
\end{equation*}
$$

By using the property (11) of matrix $P_{k}$, we have

$$
\begin{equation*}
\left\|P_{k} d_{k}\right\| \leq\left\|P_{k}\right\|\left\|d_{k}\right\|=\left\|d_{k}\right\| . \tag{55}
\end{equation*}
$$

Therefore, from inequalities (54)-(55), we obtain the estimation (45).
When $\Delta t_{k} \leq \frac{\sigma_{0}}{2\left\|B_{k}\right\|}$, by using the property $\left\|P_{k}\right\|=1$ of the projection matrix $P_{k}$, we have

$$
\begin{equation*}
\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right) \succ 0 \text { and }\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}-P_{k}^{T} B_{k} P_{k}\right) \succeq 0 . \tag{56}
\end{equation*}
$$

Thus, from equation (18) and Lemma 1, when $\Delta t_{k} \leq \frac{\sigma_{0}}{4\left\|B_{k}\right\|}$, we obtain the estimation of the predicted reduction of the horizontal step as follows.

Lemma 2 Assume that the quadratic model $q_{k}(s)$ is defined by equation (24) and $s_{k}^{p}$ is solved by the regularization method (18). Then, when $\Delta t_{k} \leq \frac{\sigma_{0}}{4\left\|B_{k}\right\|}$, we have the lower bounded estimation of $q_{0}-q_{k}\left(s_{k}^{p}\right)$ as follows:

$$
\begin{equation*}
\operatorname{Hpred}_{k}=q_{k}(0)-q_{k}\left(s_{k}^{p}\right)=q_{k}(0)-q_{k}\left(\frac{\Delta t_{k}}{1+\Delta t_{k}} P_{k} d_{k}\right) \geq \frac{1}{2}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\| \tag{57}
\end{equation*}
$$

Proof. We prove this result via considering two different cases, i.e. $\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p} \leq 0$ or $\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p}>0$. (i) When $\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p} \leq 0$, from equation (24) and equation (18), we have

$$
\begin{align*}
& q_{k}(0)-q_{k}\left(s_{k}^{p}\right)=-g_{k}^{T} s_{k}^{p}-\frac{1}{2}\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p} \geq-g_{k}^{T} s_{k}^{p}=-\frac{\Delta t_{k}}{1+\Delta t_{k}}\left(P_{k} g_{k}\right)^{T} d_{k} \\
& =\frac{\Delta t_{k}}{1+\Delta t_{k}}\left(P_{k} g_{k}\right)^{T}\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right)^{-1}\left(P_{k} g_{k}\right) \geq \frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{1}{\sigma_{0} / \Delta t_{k}+\left\|B_{k}\right\|}\left\|P_{k} g_{k}\right\|^{2} \tag{58}
\end{align*}
$$

Furthermore, from equation (18), when $\Delta t_{k}<\frac{\sigma_{0}}{\left\|\boldsymbol{B}_{k}\right\|}$, we have

$$
\begin{align*}
\left\|P_{k} g_{k}\right\| & =\left\|\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right) d_{k}\right\| \geq\left(\sigma_{0} / \Delta t_{k}-\left\|B_{k}\right\|\right)\left\|d_{k}\right\| \\
& \geq\left(\sigma_{0} / \Delta t_{k}-\left\|B_{k}\right\|\right)\left\|P_{k} d_{k}\right\| \tag{59}
\end{align*}
$$

By substituting equation (59) into equation (58), when $\Delta t_{k} \leq \frac{\sigma_{0}}{4\left\|B_{k}\right\|}$, we obtain

$$
\begin{align*}
& q_{k}(0)-q_{k}\left(s_{k}^{p}\right) \geq \frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{\sigma_{0} / \Delta t_{k}-\left\|B_{k}\right\|}{\sigma_{0} / \Delta t_{k}+\left\|B_{k}\right\|}\left\|P_{k} g_{k}\right\|\left\|P_{k} d_{k}\right\| \\
& \geq \frac{\sigma_{0} / \Delta t_{k}-\left\|B_{k}\right\|}{\sigma_{0} / \Delta t_{k}+\left\|B_{k}\right\|}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\| \geq \frac{4\left\|B_{k}\right\|-\left\|B_{k}\right\|}{4\left\|B_{k}\right\|+\left\|B_{k}\right\|}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\|=\frac{3}{5}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\| . \tag{60}
\end{align*}
$$

Thus, the result (57) is true for the case $\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p} \leq 0$.
(ii) When $\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p} \geq 0$, i.e. $\left(P_{k} d_{k}\right)^{T} B_{k}\left(P_{k} d_{k}\right) \geq 0$, from equation (24) and equation (18), we have

$$
\begin{align*}
& q_{k}(0)-q_{k}\left(s_{k}^{p}\right)=-g_{k}^{T} s_{k}^{p}-\frac{1}{2}\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p} \\
& =-\frac{\Delta t_{k}}{1+\Delta t_{k}} g_{k}^{T}\left(P_{k} d_{k}\right)-\frac{1}{2}\left(\frac{\Delta t_{k}}{1+\Delta t_{k}}\right)^{2}\left(P_{k} d_{k}\right)^{T} B_{k}\left(P_{k} d_{k}\right) \\
& \geq \frac{\Delta t_{k}}{1+\Delta t_{k}}\left(-g_{k}^{T}\left(P_{k} d_{k}\right)-\frac{1}{2}\left(P_{k} d_{k}\right)^{T} B_{k}\left(P_{k} d_{k}\right)\right)=\frac{\Delta t_{k}}{1+\Delta t_{k}}\left(q_{k}(0)-q_{k}\left(P_{k} d_{k}\right)\right) . \tag{61}
\end{align*}
$$

When $\Delta t_{k} \leq \frac{\sigma_{0}}{4\left\|B_{k}\right\|}$, by substituting equation (45) and equation (59) into equation (61), we obtain

$$
\begin{align*}
& q_{k}(0)-q_{k}\left(s_{k}^{p}\right) \geq \frac{1}{2} \frac{\Delta t_{k}}{1+\Delta t_{k}}\left\|P_{k} g_{k}\right\| \min \left\{\left\|P_{k} d_{k}\right\|, \frac{\left\|P_{k} g_{k}\right\|}{3\left\|B_{k}\right\|}\right\} \\
& \quad \geq \frac{1}{2} \frac{\Delta t_{k}}{1+\Delta t_{k}}\left\|P_{k} g_{k}\right\| \min \left\{\left\|P_{k} d_{k}\right\|, \frac{\left(\sigma_{0} / \Delta t_{k}-\left\|B_{k}\right\|\right)\left\|P_{k} d_{k}\right\|}{3\left\|B_{k}\right\|}\right\} \\
& \quad \geq \frac{1}{2} \frac{\Delta t_{k}}{1+\Delta t_{k}}\left\|P_{k} g_{k}\right\|\left\|P_{k} d_{k}\right\|=\frac{1}{2}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\| \tag{62}
\end{align*}
$$

Thus, the result (57) is also true for the case $\left(s_{k}^{p}\right)^{T} B_{k} s_{k}^{p}>0$.
In the following analysis of Algorithm 2, $f(x)$ and $c(x)$ are assumed to satisfy Assumption 1.

Assumption 1 Assume that $f(x)$ is twice continuously differentiable and $c(x)$ is continuously differentiable, that the sequence $\left\{x_{k}\right\}$ is generated by Algorithm 2 in an open set S , that $\nabla f(x), \nabla^{2} f(x), A(x)$ are bounded above on S . We also assume that $\left\|B_{k}\right\|(k=0,1,2, \ldots)$ are uniformly bounded. Namely, there exists three positive constants $M_{B}, M_{g}, M_{A}$ such that

$$
\begin{align*}
& \left\|\nabla^{2} f(x)\right\| \leq M_{B},\|A(x)\| \leq M_{A},\left\|A(x)^{\dagger}\right\| \leq M_{A}, \forall x \in \mathrm{~S} \\
& \text { and }\left\|B_{k}\right\| \leq M_{B},\left\|\nabla f\left(x_{k}\right)\right\| \leq M_{g}, k=0,1,2, \ldots \tag{63}
\end{align*}
$$

hold.
By combining the property $\left\|P_{k}\right\|=1$ of the projection matrix $P_{k}$, from the assumption (63), we obtain

$$
\begin{align*}
& \left\|P_{k} \nabla^{2} f\left(x_{k}\right) P_{k}\right\| \leq\left\|P_{k}\right\|\left\|\nabla^{2} f\left(x_{k}\right)\right\|\left\|P_{k}\right\|=\left\|\nabla^{2} f\left(x_{k}\right)\right\| \leq M_{B}, \\
& \left\|P_{k} B_{k} P_{k}\right\| \leq\left\|P_{k}\right\|\left\|B_{k}\right\|\left\|P_{k}\right\|=\left\|B_{k}\right\| \leq M_{B}, k=0,1,2, \ldots \tag{64}
\end{align*}
$$

According to the property of the matrix norm, we know that the absolute eigenvalue of $P_{k} \nabla^{2} f\left(x_{k}\right) P_{k}$ is less than $M_{B}$. If we denote $\mu\left(P_{k} \nabla^{2} f\left(x_{k}\right) P_{k}\right)$ as the eigenvalue of $P_{k} \nabla^{2} f\left(x_{k}\right) P_{k}$, we know that the eigenvalue of $\left(\frac{\sigma_{0}}{\Delta t_{k}} I+P_{k} \nabla^{2} f\left(x_{k}\right) P_{k}\right)$ is $\frac{\sigma_{0}}{\Delta t_{k}}+$ $\mu\left(P_{k} \nabla^{2}\left(f_{k}\right) P_{k}\right)$. Consequently, from equation (64), we known that

$$
\begin{equation*}
\frac{\sigma_{0}}{\Delta t_{k}} I+P_{k} \nabla^{2} f\left(x_{k}\right) P_{k} \succ 0, \text { when } \Delta t_{k}<\frac{\sigma_{0}}{M_{B}} \tag{65}
\end{equation*}
$$

In order to prove the global convergence of Algorithm 2, we need to prove the iteration sequence $\left\{x_{k}\right\}$ preserves the constraint feasible $c\left(x_{k}\right) \approx 0$ and its convergence point $x^{*}$ satisfies the KKT condition (2). In the following Lemma 3, we prove that the iteration sequence $\left\{x_{k}\right\}$ generated by Algorithm 2 will preserve on the neighbourhood of the feasibility $c(x)=0$ when the time steps $\Delta t_{k}(k=0,1, \ldots)$ are sufficiently small. The proof of the convergence point $x^{*}$ satisfying the KKT condition (2) is left to Theorem 1.

Lemma 3 Assume that $c(x)$ is continuously differentiable and its Jacobian matrix $A(x)$ is Lipschitz continuous. Namely, there exists a positive constant $L_{A}$ such that

$$
\begin{equation*}
\|A(x)-A(y)\| \leq L_{A}\|x-y\|, \forall x, y \in \mathfrak{R}^{n} . \tag{66}
\end{equation*}
$$

Furthermore, we suppose $s_{k}$ is solved by equations (18)-(22) and $B_{k}, \nabla f\left(x_{k}\right)(k=$ $0,1,2, \ldots)$ are uniformly bounded. Namely, they satisfy Assumption 1. Then, there exists a positive constant $\delta_{c}$ such that

$$
\begin{equation*}
\left\|c\left(x_{k}+s_{k}\right)\right\| \leq \varepsilon_{0}, \tag{67}
\end{equation*}
$$

when $\Delta t_{k} \leq \delta_{c}, 0<\varepsilon_{0} \leq \min \left\{1 /\left(L_{A} M_{A}^{2}\right), \varepsilon\right\}$ and $\left\|c\left(x_{k}\right)\right\| \leq \varepsilon_{0}$.

Proof. When $A_{k+1}^{p}=A\left(x_{k}\right)$ and $\left\|c\left(x_{k+1}\right)\right\| \leq \varepsilon_{0}$, we obtain the result (67). Therefore, we only need to consider the case $A_{k+1}^{p}=A\left(x_{k+1}^{p}\right)$ below. From the first-order Taylor expansion and equation (22), we have

$$
\begin{align*}
& c\left(x_{k}+s_{k}\right)=c\left(x_{k}+s_{k}^{p}+s_{k}^{c}\right)=c\left(x_{k+1}^{p}+s_{k}^{c}\right)=c\left(x_{k+1}^{p}\right)+\int_{0}^{1} A\left(x_{k+1}^{p}+t s_{k}^{c}\right) s_{k}^{c} d t \\
& \quad=c\left(x_{k+1}^{p}\right)+A\left(x_{k+1}^{p}\right) s_{k}^{c}+\int_{0}^{1}\left(A\left(x_{k+1}^{p}+t s_{k}^{c}\right)-A\left(x_{k+1}^{p}\right)\right) s_{k}^{c} d t \\
& \quad=\int_{0}^{1}\left(A\left(x_{k+1}^{p}+t s_{k}^{c}\right)-A\left(x_{k+1}^{p}\right)\right) s_{k}^{c} d t \tag{68}
\end{align*}
$$

By substituting the Lipschitz continuity (66) of $A(x)$ and the bounded assumption $\left\|A(x)^{\dagger}\right\| \leq M_{A}$ into equation (68), we obtain

$$
\begin{align*}
& \left\|c\left(x_{k}+s_{k}\right)\right\| \leq \int_{0}^{1}\left\|A\left(x_{k+1}^{p}+t s_{k}^{c}\right)-A\left(x_{k+1}^{p}\right)\right\|\left\|s_{k}^{c}\right\| d t \leq \frac{1}{2} L_{A}\left\|s_{k}^{c}\right\|^{2} \\
& \quad=\frac{1}{2} L_{A}\left\|A\left(x_{k+1}^{p}\right)^{\dagger} c\left(x_{k+1}^{p}\right)\right\|^{2} \leq \frac{1}{2} L_{A}\left\|A\left(x_{k+1}^{p}\right)^{\dagger}\right\|^{2}\left\|c\left(x_{k+1}^{p}\right)\right\|^{2} \\
& \quad \leq \frac{1}{2} L_{A} M_{A}^{2}\left\|c\left(x_{k+1}^{p}\right)\right\|^{2} . \tag{69}
\end{align*}
$$

In order to estimate the upper bound of $\left\|c\left(x_{k}+s_{k}\right)\right\|$, we need to estimate the upper bound of $\left\|c\left(x_{k+1}^{p}\right)\right\|$. From the property $A_{k} P_{k}=0$ of the projection matrix $P_{k}$, we have

$$
\begin{equation*}
A_{k} s_{k}^{p}=\frac{\Delta t_{k}}{1+\Delta t_{k}} A_{k} P_{k} d_{k}=0 \tag{70}
\end{equation*}
$$

Thus, from the first-order Taylor expansion, the property (70) and the Lipschitz continuity (66) of $A(x)$, we have

$$
\begin{align*}
& \left\|c\left(x_{k+1}^{p}\right)\right\|=\left\|c\left(x_{k}\right)+\int_{0}^{1} A\left(x_{k}+t s_{k}^{p}\right) s_{k}^{p} d t\right\| \\
& \quad=\left\|c\left(x_{k}\right)+\int_{0}^{1}\left(A\left(x_{k}+t s_{k}^{p}\right)-A\left(x_{k}\right)\right) s_{k}^{p} d t\right\| \\
& \quad \leq\left\|c\left(x_{k}\right)\right\|+\int_{0}^{1}\left\|A\left(x_{k}+t s_{k}^{p}\right)-A\left(x_{k}\right)\right\|\left\|s_{k}^{p}\right\| d t \leq\left\|c\left(x_{k}\right)\right\|+\frac{1}{2} L_{A}\left\|s_{k}^{p}\right\|^{2} \tag{71}
\end{align*}
$$

Furthermore, from equation (18) and the assumption (63) of $g(x)$ and $B_{k}$, when $\Delta t_{k} \leq$ $\sigma_{0} /\left(2 M_{B}\right)$, we obtain

$$
\begin{align*}
& \left\|s_{k}^{p}\right\|=\frac{\Delta t_{k}}{1+\Delta t_{k}}\left\|\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right)^{-1} P_{k} g_{k}\right\| \leq \frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{\left\|P_{k} g_{k}\right\|}{\sigma_{0} / \Delta t_{k}-\left\|B_{k}\right\|} \\
& \quad \leq \frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{\left\|P_{k}\right\|\left\|g_{k}\right\|}{\sigma_{0} / \Delta t_{k}-M_{B}} \leq \frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{M_{g}}{2 M_{B}-M_{B}}=\frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{M_{g}}{M_{B}} \tag{72}
\end{align*}
$$

According to the inductive hypothesis, we have $\left\|c\left(x_{k}\right)\right\| \leq \varepsilon_{0}$. By substituting it and equation (72) into equation (71), when $\Delta t_{k} \leq \sigma_{0} /\left(2 M_{B}\right)$, we obtain

$$
\begin{equation*}
\left\|c\left(x_{k+1}^{p}\right)\right\| \leq \varepsilon_{0}+\frac{1}{2} L_{A}\left(\frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{M_{g}}{M_{B}}\right)^{2} \tag{73}
\end{equation*}
$$

Thus, from equation (69) and equation (73), when $\Delta t_{k} \leq \sigma_{0} /\left(2 M_{B}\right)$, we prove $\left\|c\left(x_{k}+s_{k}\right)\right\| \leq \varepsilon_{0}$ if only we prove

$$
\frac{1}{2} L_{A} M_{A}^{2}\left(\varepsilon_{0}+\frac{1}{2} L_{A}\left(\frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{M_{g}}{M_{B}}\right)^{2}\right)^{2} \leq \varepsilon_{0}
$$

Namely, when $\Delta t_{k} \leq \sigma_{0} /\left(2 M_{B}\right)$, we only need to prove

$$
\begin{equation*}
\frac{\Delta t_{k}}{1+\Delta t_{k}} \leq \frac{2 M_{B}^{2}}{L_{A} M_{g}^{2}}\left(-\varepsilon_{0}+\sqrt{\frac{2 \varepsilon_{0}}{L_{A} M_{A}^{2}}}\right) . \tag{74}
\end{equation*}
$$

We select

$$
\begin{equation*}
\delta_{c}=\min \left\{\frac{\sigma_{0}}{4 M_{B}}, \frac{\frac{2 M_{B}^{2}}{L_{A} M_{g}^{2}}\left(-\varepsilon_{0}+\sqrt{\frac{2 \varepsilon_{0}}{L_{A} M_{A}^{2}}}\right)}{\left|1-\frac{2 M_{B}^{2}}{L_{A} M_{g}^{2}}\left(-\varepsilon_{0}+\sqrt{\frac{2 \varepsilon_{0}}{L_{A} M_{A}^{2}}}\right)\right|}\right\} . \tag{75}
\end{equation*}
$$

Then, when $\Delta t_{k} \leq \delta_{c}$ and $\varepsilon_{0} \leq \min \left\{1 /\left(L_{A} M_{A}^{2}\right), \varepsilon\right\}$, we know that equation (74) is true. Namely, we have $\left\|c\left(x_{k}+s_{k}\right)\right\| \leq \varepsilon_{0}$ when $\Delta t_{k} \leq \delta_{c}$ and $\varepsilon_{0} \leq \min \left\{1 /\left(L_{A} M_{A}^{2}\right), \varepsilon\right\}$.

In order to estimate the lower bound of the time steps $\Delta t_{k}(k=1,2, \ldots)$, we need to prove the correction step $s_{k}^{c}$ is less than the predicted step $s_{k}^{p}$ and the predicted vertical reduction Vpred $_{k}$ is less than the predicted horizontal reduction Hpred $_{k}$, where $s_{k}^{c}$ is solved by equation (22), and $s_{k}^{p}$ is solved by equation (18), and Vpred $_{k}$, Hpred ${ }_{k}$ are defined by equation (25). Their proofs are given by the following Lemma 4 under some assumptions.

Lemma 4 Assume that $c(x)$ is continuously differentiable and its Jacobian matrix A(x) satisfies the Lipschitz continuity (66). Furthermore, we suppose $s_{k}^{p}$ is solved by equation (18) and $B_{k}(k=0,1,2, \ldots)$ are uniformly bounded. Namely, $B_{k}(k=$ $0,1,2, \ldots)$ satisfy equation (63). Assume that $\left\|P_{k} g_{k}\right\| \geq \varepsilon(k=0,1,2, \ldots)$. Then, there exists five positive constants $\theta_{c}, \theta_{v}, \delta_{0}, \delta_{v}$ and $\delta_{\varepsilon_{0}}$ such that

$$
\begin{equation*}
\left\|s_{k}^{c}\right\| \leq \theta_{c}\left\|s_{k}^{p}\right\|^{2} \text { and }\left|\operatorname{Vpred}_{k}\right| \leq \theta_{v}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\|, \tag{76}
\end{equation*}
$$

when $\delta_{0} \leq \Delta t_{k} \leq \delta_{v}, \quad 0<\varepsilon_{0} \leq \delta_{\varepsilon_{0}}$ and $\left\|c\left(x_{k}\right)\right\| \leq \varepsilon_{0}$, where $0<\theta_{v}<1 / 2$, s $s_{k}^{c}$ is solved by equation (22), and $V p r e d_{k}$ is defined by equation (25).

Proof. From equation (18), when $\Delta t_{k}<\sigma_{0} /\left\|B_{k}\right\|$, we have

$$
P_{k} d_{k}=-P_{k}\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right)^{-1} P_{k} g_{k} .
$$

By combining it with the Cauchy-Schwartz inequality $\left|x^{T} y\right| \leq\|x\|\|y\|$ and $P_{k}^{2}=P_{k}$, when $\Delta t_{k}<\sigma_{0} /\left\|B_{k}\right\|$, we have

$$
\begin{align*}
& \left\|P_{k} g_{k}\right\|\left\|P_{k} d_{k}\right\| \geq\left|g_{k}^{T} P_{k}^{2} d_{k}\right|=\left|\left(P_{k} g_{k}\right)^{T}\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right)^{-1}\left(P_{k} g_{k}\right)\right| \\
& \quad \geq \frac{1}{\sigma_{0} / \Delta t_{k}+\left\|B_{k}\right\|}\left\|P_{k} g_{k}\right\|^{2} \tag{77}
\end{align*}
$$

Namely, when $\Delta t_{k}<\sigma_{0} /\left\|B_{k}\right\|$, from equation (77), we have

$$
\begin{equation*}
\left\|s_{k}^{p}\right\|=\left\|\frac{\Delta t_{k}}{1+\Delta t_{k}} P_{k} d_{k}\right\|=\frac{\Delta t_{k}}{1+\Delta t_{k}}\left\|P_{k} d_{k}\right\| \geq \frac{\Delta t_{k}}{1+\Delta t_{k}} \frac{1}{\sigma_{0} / \Delta t_{k}+\left\|B_{k}\right\|}\left\|P_{k} g_{k}\right\| \tag{78}
\end{equation*}
$$

Thus, according to the assumptions $\left\|B_{k}\right\| \leq M_{B}$ and $\left\|P_{k} g_{k}\right\| \geq \varepsilon$, when $\delta_{0} \leq \Delta t_{k}<$ $\sigma_{0} / M_{B}$, from equation (78), we have

$$
\begin{equation*}
\left\|s_{k}^{p}\right\| \geq \frac{\delta_{0}}{1+\delta_{0}} \frac{1}{\sigma_{0} / \delta_{0}+M_{B}} \varepsilon=\frac{\delta_{0} \varepsilon}{\left(1+\delta_{0}\right)\left(\sigma_{0} / \delta_{0}+M_{B}\right)} \tag{79}
\end{equation*}
$$

From equation (22), the Lipschitz continuity (66) and equation (71), we have

$$
\begin{align*}
\left\|s_{k}^{c}\right\| & =\left\|A\left(x_{k+1}^{p}\right)^{\dagger} c\left(x_{k+1}^{p}\right)\right\| \leq M_{A}\left\|c\left(x_{k+1}^{p}\right)\right\|=M_{A}\left\|c\left(x_{k}+s_{k}^{p}\right)\right\| \\
& \leq M_{A}\left(\left\|c\left(x_{k}\right)\right\|+\frac{1}{2} L_{A}\left\|s_{k}^{p}\right\|^{2}\right) \leq M_{A}\left(\varepsilon_{0}+\frac{1}{2} L_{A}\left\|s_{k}^{p}\right\|^{2}\right) \tag{80}
\end{align*}
$$

We select

$$
\begin{equation*}
\delta_{\varepsilon_{0}}=\min \left\{\left(\frac{\delta_{0} \varepsilon}{\left(1+\delta_{0}\right)\left(\sigma_{0} / \delta_{0}+M_{B}\right)}\right)^{2}, \frac{1}{L_{A} M_{A}^{2}}\right\} \tag{81}
\end{equation*}
$$

Then, from equations (79)-(81), when $\varepsilon_{0} \leq \delta_{\varepsilon_{0}}$, we have

$$
\begin{equation*}
\left\|s_{k}^{c}\right\| \leq M_{A}\left(1+\frac{1}{2} L_{A}\right)\left\|s_{k}^{p}\right\|^{2}=\theta_{c}\left\|s_{k}^{p}\right\|^{2} \tag{82}
\end{equation*}
$$

where we select $\theta_{c}=M_{A}\left(1+0.5 L_{A}\right)$. Thus, we prove the first inequality of equation (76).

From equation (18), when $\Delta t_{k} \leq \sigma_{0} /\left(2 M_{B}\right)$, we have

$$
\begin{align*}
& \left\|s_{k}^{p}\right\|=\left\|\frac{\Delta t_{k}}{1+\Delta t_{k}} P_{k} d_{k}\right\| \leq\left\|P_{k} d_{k}\right\| \leq\left\|d_{k}\right\|=\left\|\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right)^{-1} P_{k} g_{k}\right\| \\
& \quad \leq \frac{1}{\sigma_{0} / \Delta t_{k}-M_{B}}\left\|P_{k} g_{k}\right\| \leq \frac{M_{g}}{M_{B}} \tag{83}
\end{align*}
$$

Thus, from equation (25), equation (82) and the assumption (63), we have

$$
\begin{align*}
& \mid \text { Vpred }_{k}\left|=\left|q_{k}\left(s_{k}^{p}\right)-q_{k}\left(s_{k}^{p}+s_{k}^{c}\right)\right|=\left|\left(s_{k}^{c}\right)^{T} \nabla q_{k}\left(s_{k}^{p}\right)+\frac{1}{2}\left(s_{k}^{c}\right)^{T} \nabla^{2} q_{k}\left(s_{k}^{p}\right) s_{k}^{c}\right|\right. \\
& \quad=\left|\left(s_{k}^{c}\right)^{T}\left(g_{k}+B_{k} s_{k}^{p}+\frac{1}{2} B_{k} s_{k}^{c}\right)\right| \leq\left\|s_{k}^{c}\right\|\left\|g_{k}+B_{k} s_{k}^{p}+\frac{1}{2} B_{k} s_{k}^{c}\right\| \\
& \quad \leq\left\|s_{k}^{c}\right\|\left(\left\|g_{k}\right\|+\left\|B_{k}\right\|\left(\left\|s_{k}^{p}\right\|+\left\|s_{k}^{c}\right\|\right)\right) \leq \theta_{c}\left(M_{g}+M_{B}\left(\left\|s_{k}^{p}\right\|+\left\|s_{k}^{c}\right\|\right)\right)\left\|s_{k}^{p}\right\|^{2} . \tag{84}
\end{align*}
$$

By substituting equation (82) and equation (83) into equation (84), when $\Delta t_{k} \leq$ $\sigma_{0} /\left(2 M_{B}\right)$, we obtain

$$
\begin{equation*}
\mid \text { Vpred }_{k} \left\lvert\, \leq \frac{\theta_{c}\left(2 M_{g} M_{B}+\theta_{c} M_{g}^{2}\right)}{M_{B}}\left\|s_{k}^{p}\right\|^{2} \leq \frac{\theta_{c}\left(2 M_{g} M_{B}+\theta_{c} M_{g}^{2}\right)}{M_{B}\left(\sigma_{0} / \Delta t_{k}-M_{B}\right)}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\|\right. \tag{85}
\end{equation*}
$$

We select

$$
\begin{equation*}
\delta_{v}=\min \left\{\frac{\sigma_{0}}{4 M_{B}}, \delta_{c}, \frac{\sigma_{0} M_{B} \theta_{v}}{\left(2 M_{g} M_{B}+\theta_{c} M_{g}^{2}\right) \theta_{c}+M_{B}^{2} \theta_{v}}\right\} \tag{86}
\end{equation*}
$$

where the positive constant $\delta_{c}$ is defined by equation (75). Thus, from equations (85)(86), when $\Delta t_{k} \leq \delta_{v}$, we have $\left|\operatorname{Vpred}_{k}\right| \leq \theta_{v}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\|$. We select the small positive constant $\delta_{0}$ to satisfy $\delta_{0} \leq \delta_{v}$. Then, by combining equation (82), when $\delta_{0} \leq \Delta t_{k} \leq \delta_{v}$ and $\varepsilon_{0} \leq \delta_{\varepsilon_{0}}$, we obtain the result (76).

Remark 7 We select

$$
\begin{equation*}
\theta_{1} \geq \frac{\theta_{c} M_{g}}{M_{B}} . \tag{87}
\end{equation*}
$$

Then, from equations (82)-(87), when $\delta_{0} \leq \Delta t_{k}<\sigma_{0} /\left(2 M_{B}\right)$ and $\varepsilon_{0} \leq \delta_{\varepsilon_{0}}$, we have

$$
\begin{equation*}
\left\|s_{k}^{c}\right\| \leq \theta_{1}\left\|s_{k}^{p}\right\| . \tag{88}
\end{equation*}
$$

Namely, the condition (26) is satisfied.

In order to prove that $p_{g_{k}}$ converges to zero when $k$ tends to infinity, we need to estimate the lower bound of time step sizes $\Delta t_{k}(k=1,2, \ldots)$. By using Lemma 2, Lemma 3 and Lemma 4, we can obtain the lower bound of time step sizes $\Delta t_{k}(k=$ $1,2, \ldots)$ as follows.

Lemma 5 Assume that $f: \mathfrak{R}^{n} \rightarrow \mathfrak{R}$ is twice continuously differentiable and $\nabla f(x)$ is Lipschitz continuous. Namely, there exists a positive constant $L_{g}$ such that

$$
\begin{equation*}
\|\nabla f(x)-\nabla f(y)\| \leq L_{g}\|x-y\|, \forall x, y \in \mathfrak{R}^{n} . \tag{89}
\end{equation*}
$$

Assume that $c(x)$ is continuously differentiable and its Jacobian matrix $A(x)$ satisfies the Lipschitz continuity (66). We suppose that the sequence $\left\{x_{k}\right\}$ is generated by Algorithm 2 and Assumption 1 holds. Furthermore, we assume

$$
\begin{equation*}
\left\|P_{k} g_{k}\right\|>\varepsilon \tag{90}
\end{equation*}
$$

holds for all $k=0,1,2, \ldots$, where $g_{k}=g\left(x_{k}\right)=\nabla f\left(x_{k}\right), P_{k}=P\left(x_{k}\right)$ and the projection matrix $P(x)$ is defined by equation (10). Then, it exists a positive constant $\delta_{\Delta t}$ such that

$$
\begin{equation*}
\Delta t_{k} \geq \gamma_{2} \delta_{\Delta t}>0, k=0,1,2, \ldots \tag{91}
\end{equation*}
$$

where $\Delta t_{k}$ is adaptively adjusted by the trust-region updating strategy (27)-(29).
Proof. According to Lemma 3, by induction, when $\delta_{0} \leq \Delta t_{k} \leq \delta_{v}$ and $0<\varepsilon_{0} \leq \delta_{\varepsilon_{0}}$, we have

$$
\begin{equation*}
\left\|c\left(x_{k}\right)\right\| \leq \varepsilon_{0}, k=0,1,2, \ldots \tag{92}
\end{equation*}
$$

where $\delta_{\varepsilon_{0}}$ is defined by equation (81) and $\delta_{v}$ is defined by equation (86).
From equation (11), we know $\left\|P_{k}\right\|=1$. By using this property and the assumption (63), we have

$$
\begin{align*}
& \left|\mu_{\min }\left(B_{k}-P_{k}^{T} B_{k} P_{k}\right)\right| \leq\left\|B_{k}-P_{k}^{T} B_{k} P_{k}\right\| \\
& \quad \leq\left\|B_{k}\right\|+\left\|P_{k}^{T}\right\|\left\|B_{k}\right\|\left\|P_{k}\right\|=2\left\|B_{k}\right\| \leq 2 M_{B}, k=0,1,2, \ldots \tag{93}
\end{align*}
$$

where $\mu_{\min }(B)$ represents the smallest eigenvalue of matrix $B$. Thus, from equation (93), we obtain

$$
\begin{align*}
& \mu_{\min }\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}-P_{k}^{T} B_{k} P_{k}\right)=\frac{\sigma_{0}}{\Delta t_{k}}+\mu_{\min }\left(B_{k}-P_{k}^{T} B_{k} P_{k}\right) \\
& \quad \geq \frac{\sigma_{0}}{\Delta t_{k}}-2 M_{B}, k=0,1,2, \ldots \tag{94}
\end{align*}
$$

Similarly, from the assumption (63), we have

$$
\begin{equation*}
\mu_{\min }\left(\frac{\sigma_{0}}{\Delta t_{k}} I+B_{k}\right)=\frac{\sigma_{0}}{\Delta t_{k}}+\mu_{\min }\left(B_{k}\right) \geq \frac{\sigma_{0}}{\Delta t_{k}}-M_{B}, k=0,1,2, \ldots \tag{95}
\end{equation*}
$$

Therefore, the positive definite conditions of equation (44) are satisfied when $\Delta t_{k} \leq$ $\sigma_{0} /\left(2 M_{B}\right)(k=1,2, \ldots)$.

From the Lipschitz continuity (89) of $\nabla f(x)$ and the Cauchy-Schwartz inequality $\left|x^{T} y\right| \leq\|x\|\|y\|$, we have

$$
\begin{align*}
& \left|\int_{0}^{1}\left(\nabla f\left(x_{k}+t s_{k}\right)-\nabla f\left(x_{k}\right)\right)^{T} s_{k} d t\right| \leq \int_{0}^{1}\left\|\nabla f\left(x_{k}+t s_{k}\right)-\nabla f\left(x_{k}\right)\right\|\left\|s_{k}\right\| d t \\
& \quad \leq \int_{0}^{1} L_{g}\left\|s_{k}\right\|^{2} t d t=\frac{1}{2} L_{g}\left\|s_{k}\right\|^{2}=\frac{1}{2} L_{g}\left(\left\|s_{k}^{p}+s_{k}^{c}\right\|\right)^{2} \leq \frac{1}{2} L_{g}\left(\left\|s_{k}^{p}\right\|+\left\|s_{k}^{c}\right\|\right)^{2} \tag{96}
\end{align*}
$$

By substituting equation (76) and equation (83) into equation (96), when $\delta_{0} \leq \Delta t_{k} \leq$ $\delta_{v}$ and $0<\varepsilon_{0} \leq \delta_{\varepsilon_{0}}$, we obtain

$$
\begin{align*}
& \left|\int_{0}^{1}\left(\nabla f\left(x_{k}+t s_{k}\right)-\nabla f\left(x_{k}\right)\right)^{T} s_{k} d t\right| \leq \frac{1}{2} L_{g}\left(\left\|s_{k}^{p}\right\|+\theta_{c}\left\|s_{k}^{p}\right\|^{2}\right)^{2} \\
& \quad \leq \frac{1}{2} L_{g}\left(1+\frac{\theta_{c} M_{g}}{M_{B}}\right)^{2}\left\|s_{k}^{p}\right\|^{2} \tag{97}
\end{align*}
$$

and

$$
\begin{align*}
& \frac{1}{2}\left|s_{k}^{T} B_{k} s_{k}\right| \leq \frac{1}{2}\left\|B_{k}\right\|\left\|s_{k}\right\|^{2} \leq \frac{1}{2} M_{B}\left\|s_{k}^{p}+s_{k}^{c}\right\|^{2} \leq \frac{1}{2} M_{B}\left(\left\|s_{k}^{p}\right\|+\left\|s_{k}^{c}\right\|\right)^{2} \\
& \leq \frac{1}{2} M_{B}\left(\left\|s_{k}^{p}\right\|+\theta_{c}\left\|s_{k}^{p}\right\|^{2}\right)^{2}=\frac{1}{2} M_{B}\left(1+\theta_{c}\left\|s_{k}^{p}\right\|\right)^{2}\left\|s_{k}^{p}\right\|^{2} \\
& \leq \frac{1}{2} M_{B}\left(1+\theta_{c} \frac{M_{g}}{M_{B}}\right)^{2}\left\|s_{k}^{p}\right\|^{2} . \tag{98}
\end{align*}
$$

From the first-order Taylor expansion of $f\left(x_{k}+s_{k}\right)$ and equation (97), we have

$$
\begin{align*}
& \left|f\left(x_{k}\right)-f\left(x_{k}+s_{k}\right)+\nabla f\left(x_{k}\right)^{T} s_{k}\right|=\left|\nabla f\left(x_{k}\right)^{T} s_{k}-\int_{0}^{1} \nabla f\left(x_{k}+t s_{k}\right)^{T} s_{k} d t\right| \\
& =\left|\int_{0}^{1}\left(\nabla f\left(x_{k}\right)-\nabla f\left(x_{k}+t s_{k}\right)\right)^{T} s_{k} d t\right| \leq \frac{1}{2} L_{g}\left(1+\frac{\theta_{c} M_{g}}{M_{B}}\right)^{2}\left\|s_{k}^{p}\right\|^{2} . \tag{99}
\end{align*}
$$

From equation (57) and equation (76), we have

$$
\begin{align*}
& q_{k}(0)-q_{k}\left(s_{k}\right)=\left(q_{k}(0)-q_{k}\left(s_{k}^{p}\right)\right)-\left(q_{k}\left(s_{k}^{p}\right)-q_{k}\left(s_{k}^{p}+s_{k}^{c}\right)\right) \\
& \geq \frac{1}{2}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\|-\theta_{v}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\|=\left(0.5-\theta_{v}\right)\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\| . \tag{100}
\end{align*}
$$

Thus, from equations (24), (27), (57), (76) and (98)-(100), when $\delta_{0} \leq \Delta t_{k} \leq \delta_{v}$ and $0<\varepsilon_{0} \leq \delta_{\varepsilon_{0}}$, we have

$$
\begin{align*}
& \left|\rho_{k}-1\right|=\left|\frac{\left(f\left(x_{k}\right)-f\left(x_{k}+s_{k}\right)\right)-\left(q_{k}(0)-q_{k}\left(s_{k}\right)\right)}{q_{k}(0)-q_{k}\left(s_{k}\right)}\right| \\
& \leq \frac{0.5\left(L_{g}+M_{B}\right)\left(1+\left(\theta_{c} M_{g}\right) / M_{B}\right)^{2}\left\|s_{k}^{p}\right\|^{2}}{\left|q_{k}(0)-q_{k}\left(s_{k}\right)\right|} \\
& \leq \frac{0.5\left(L_{g}+M_{B}\right)\left(1+\left(\theta_{c} M_{g}\right) / M_{B}\right)^{2}\left\|s_{k}^{p}\right\|^{2}}{\left\|q_{k}(0)-q_{k}\left(s_{k}^{p}\right)|-| q_{k}\left(s_{k}^{p}\right)-q_{k}\left(s_{k}^{p}+s_{k}^{c}\right)\right\|} \\
& \leq \frac{0.5\left(L_{g}+M_{B}\right)\left(1+\left(\theta_{c} M_{g}\right) / M_{B}\right)^{2}\left\|s_{k}^{p}\right\|^{2}}{\left(0.5-\theta_{v}\right)\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\|} \tag{101}
\end{align*}
$$

By substituting equation (83) into equation (101), we obtain

$$
\begin{equation*}
\left|\rho_{k}-1\right| \leq \frac{0.5\left(L_{g}+M_{B}\right)\left(1+\left(\theta_{c} M_{g}\right) / M_{B}\right)^{2}}{\left(0.5-\theta_{v}\right)\left(\sigma_{0} / \Delta t_{k}-M_{B}\right)} \tag{102}
\end{equation*}
$$

We denote

$$
\begin{align*}
& \delta_{u b}=\frac{\left(0.5-\theta_{v}\right)\left(1-\eta_{2}\right) \sigma_{0}}{0.5\left(L_{g}+M_{B}\right)\left(1+\left(\theta_{c} M_{g}\right) / M_{B}\right)^{2}+\left(0.5-\theta_{v}\right)\left(1-\eta_{2}\right) M_{B}}, \\
& \delta_{\Delta t} \triangleq \min \left\{\delta_{u b}, \frac{\sigma_{0}}{4 M_{B}}, \delta_{v}, \Delta t_{0}\right\} . \tag{103}
\end{align*}
$$

Thus, from equations (102)-(103), when $\delta_{0} \leq \Delta t_{k} \leq \delta_{\Delta t}$, we have $\rho_{k} \geq \eta_{2}$. We select $\delta_{0} \leq \gamma_{2} \delta_{\Delta t}$. We assume that $K$ is the first index such that $\Delta t_{K} \leq \delta_{\Delta t}$. Then, from equations (102)-(103), we know that $\rho_{K} \geq \eta_{2}$. According to the time-stepping adjustment formula (29) and Lemma 3, when $0<\varepsilon_{0} \leq \delta_{\varepsilon_{0}}, x_{K}+s_{K}$ will be accepted and the time step $\Delta t_{K+1}$ will be enlarged. Consequently, $\Delta t_{k} \geq \gamma_{2} \delta_{\Delta t}$ holds for all $k=0,1,2, \ldots$.

Remark 8 We select $\eta_{q} \leq 0.5-\theta_{v}$. Then, when $\delta_{0} \leq \Delta t_{k} \leq \delta_{v}$, from equation (100), we have

$$
\begin{equation*}
q_{k}(0)-q_{k}\left(s_{k}\right) \geq\left(0.5-\theta_{v}\right)\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\| \geq \eta_{q}\left\|P_{k} g_{k}\right\|\left\|s_{k}^{p}\right\| . \tag{104}
\end{equation*}
$$

Namely, the sufficient descent condition (28) is satisfied.
By using the results of Lemma 3 and Lemma 5, we prove the global convergence of Algorithm 2 for the equality-constrained optimization problem (1) as follows.

Theorem 1 Assume that Assumption 1 holds, $\nabla f(x)$ satisfies the Lipschitz continuity (89), and the Jacobian matrix $A(x)$ of $c(x)$ satisfies the Lipschitz continuity (66). We suppose that the sequence $\left\{x_{k}\right\}$ is generated by Algorithm 2 and $f\left(x_{k}\right)(k=0,1, \ldots)$ are bounded below. Then, for any positive constant $\varepsilon$, we can select a sufficiently small constant $\varepsilon_{0}>0$ such that

$$
\begin{equation*}
\left\|P_{K} g_{K}\right\| \leq \varepsilon \text { and }\left\|c\left(x_{K}\right)\right\| \leq \varepsilon_{0} \tag{105}
\end{equation*}
$$

hold for an index $K$ when $\left\|c\left(x_{0}\right)\right\| \leq \varepsilon_{0}$.
Proof. We prove this result by contradiction. Assume that the result (105) is not true. Then, we have

$$
\begin{equation*}
\left\|P_{k} g_{k}\right\|>\varepsilon \text { for all } k=0,1,2, \ldots \tag{106}
\end{equation*}
$$

Thus, from Lemma 3 and Lemma 5, we can select a sufficiently small constant $\varepsilon_{0}>0$ and there exists an infinite subsequence $\left\{x_{k_{i}}\right\}$ such that the trial steps $s_{k_{i}}$ are accepted, i.e., $\rho_{k_{i}} \geq \eta_{a}, i=1,2, \ldots$. Otherwise, all steps are rejected after a given iteration index, then the time step will keep decreasing, which contradicts (91). Therefore, from equation (27), we have $\left\|c\left(x_{k_{i}}\right)\right\| \leq \varepsilon_{0}$ and

$$
\begin{equation*}
f_{0}-\lim _{k \rightarrow \infty} f_{k}=\sum_{k=0}^{\infty}\left(f_{k}-f_{k+1}\right) \geq \eta_{a} \sum_{i=0}^{\infty}\left(q_{k_{i}}(0)-q_{k_{i}}\left(s_{k_{i}}\right)\right), \tag{107}
\end{equation*}
$$

where $s_{k_{i}}$ is computed by equation (18) and equation (22).
Since $f_{k}=f\left(x_{k}\right)(k=0,1,2, \ldots)$ are bounded below and the sequence $\left\{f_{k}\right\}$ decreases monotonically, we know that the limit of the sequence $\left\{f\left(x_{k}\right)\right\}$ exits and we denote it as $\lim _{k \rightarrow \infty} f_{k}=f^{*}$. Thus, from equation (107), we have

$$
\begin{equation*}
\lim _{k_{i} \rightarrow \infty}\left(q_{k_{i}}(0)-q_{k_{i}}\left(s_{k_{i}}\right)\right)=0 . \tag{108}
\end{equation*}
$$

By substituting equation (28) into equation (108), we obtain

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\|p_{g_{k_{i}}}\right\|\left\|s_{k_{i}}^{p}\right\|=0 \tag{109}
\end{equation*}
$$

According to the assumption $\left\|P_{k} g_{k}\right\|>\varepsilon>0$, from equation (109), we have

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\|s_{k_{i}}^{p}\right\|=0 \tag{110}
\end{equation*}
$$

From Lemma 5, we know that it exists a positive constant $\delta_{\Delta t}$ such that

$$
\begin{equation*}
\Delta t_{k} \geq \gamma_{2} \delta_{\Delta t}>0, k=0,1,2, \ldots \tag{111}
\end{equation*}
$$

(i) When $B_{k_{i}}$ is updated by the BFGS quasi-Newton formula (30), we know that $B_{k_{i}} \succ 0$. Thus, by substituting equation (111) into equation (78), we have

$$
\begin{align*}
\left\|s_{k_{i}}^{p}\right\| & \geq \frac{\Delta t_{k_{i}}}{1+\Delta t_{k_{i}}} \frac{1}{\sigma_{0} / \Delta t_{k_{i}}+\left\|B_{k_{i}}\right\|}\left\|P_{k_{i}} g_{k_{i}}\right\| \\
& \geq \frac{\gamma_{2} \delta_{\Delta t}}{1+\gamma_{2} \delta_{\Delta t}} \frac{1}{\sigma_{0} /\left(\gamma_{2} \delta_{\Delta t}\right)+M_{B}}\left\|P_{k_{i}} g_{k_{i}}\right\| . \tag{112}
\end{align*}
$$

(ii) When $B_{k_{i}}=P_{k_{i}} \nabla^{2} f\left(x_{k_{i}}\right) P_{k_{i}}$, from equation (18), we have

$$
\begin{aligned}
& P_{k_{i}}\left(\frac{\sigma_{0}}{\Delta t_{k_{i}}} I+P_{k_{i}} \nabla^{2} f\left(x_{k_{i}}\right) P_{k_{i}}\right) d_{k_{i}}=-P_{k_{i}}^{2} g_{k_{i}} \\
& \quad=-P_{k_{i}} g_{k_{i}}=\left(\frac{\sigma_{0}}{\Delta t_{k_{i}}} I+P_{k_{i}} \nabla^{2} f\left(x_{k_{i}}\right) P_{k_{i}}\right) d_{k_{i}}
\end{aligned}
$$

which gives $P_{k_{i}} d_{k_{i}}=d_{k_{i}}$. By combining it with equation (18) and equation (111), we have

$$
\begin{align*}
& \frac{\gamma_{2} \delta_{\Delta t}}{1+\gamma_{2} \delta_{\Delta t}}\left\|P_{k_{i}} g_{k_{i}}\right\| \leq\left\|\frac{\Delta t_{k_{i}}}{1+\Delta t_{k_{i}}} P_{k_{i}} g_{k_{i}}\right\| \\
& \quad=\left\|\frac{\Delta t_{k_{i}}}{1+\Delta t_{k_{i}}}\left(\frac{\sigma_{0}}{\Delta t_{k_{i}}} I+P_{k_{i}} \nabla^{2} f\left(x_{k_{i}}\right) P_{k_{i}}\right) d_{k_{i}}\right\| \\
& =\left\|\frac{\Delta t_{k_{i}}}{1+\Delta t_{k_{i}}}\left(\frac{\sigma_{0}}{\Delta t_{k_{i}}} I+P_{k_{i}} \nabla^{2} f\left(x_{k_{i}}\right) P_{k_{i}}\right) P_{k_{i}} d_{k_{i}}\right\| \\
& \quad=\left\|\left(\frac{\sigma_{0}}{\Delta t_{k_{i}}} I+P_{k_{i}} \nabla^{2} f\left(x_{k_{i}}\right) P_{k_{i}}\right) s_{k_{i}}^{p}\right\| \\
& \leq\left(\frac{\sigma_{0}}{\Delta t_{k_{i}}}+\left\|B_{k_{i}}\right\|\right)\left\|s_{k_{i}}^{p}\right\| \leq\left(\frac{\sigma_{0}}{\gamma_{2} \delta_{\Delta t}}+M_{B}\right)\left\|s_{k_{i}}^{p}\right\| . \tag{113}
\end{align*}
$$

By substituting equations (112)-(113) into equation (110), we obtain

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\|P_{k_{i}} g_{k_{i}}\right\|=0 \tag{114}
\end{equation*}
$$

which contradicts the bounded assumption (106) of $P_{k} g_{k}(k=0,1,2, \ldots)$. Therefore, the result (105) is true.

## 4 Numerical Experiments

In this section, we conduct some numerical experiments to test the performance of Algorithm 2 (the Rcm method). The codes are executed by a HP notebook with the Intel quad-core CPU and 8 Gb memory in the MATLAB R2020a environment [60]. For a real-world problem, the analytical Hessian matrix $\nabla^{2} f\left(x_{k}\right)$ may not be offered. Thus, in practice, we replace the two sided projection $P\left(x_{k}\right) \nabla^{2} f\left(x_{k}\right) P\left(x_{k}\right)$ of the Hessian matrix with its difference approximation as follows:

$$
\begin{equation*}
P_{k} \nabla^{2} f\left(x_{k}\right) P_{k} \approx\left[\frac{P_{k} g\left(x_{k}+\varepsilon P_{k} e_{1}\right)-P_{k} g\left(x_{k}\right)}{\varepsilon}, \ldots, \frac{P_{k} g\left(x_{k}+\varepsilon P_{k} e_{n}\right)-P_{k} g\left(x_{k}\right)}{\varepsilon}\right], \tag{115}
\end{equation*}
$$

where the elements of $e_{i}$ equal zeros except for the $i$-th element which equals 1 , $P_{k}=P\left(x_{k}\right)$ and the parameter $\varepsilon$ can be selected as $10^{-6}$ according to our numerical experiments.

SQP [19, $25,65,85]$ is a representative method for constrained optimization problems. And there are two representative implementation codes of the SQP method. One is the built-in subroutine fmincon.m (NLPQL) of the MATLAB2020a environment $[60,72]$. The other is the subroutine SNOPT $[29,30]$ executed in GAMS v28.2 (2019) environment [23]). fmincon and SNOPT are two robust and efficient solvers for nonlinear equality-constrained optimization problems. Therefore, we select these two typical solvers as the basis for comparison.

We select 65 nonlinear equality-constrained optimization problems from CUTEst [26] and construct 60 test problems. Therefore, we use these 125 problems to test their performance of these three algorithms (Rcm, fmincon and SNOPT). For those 60 constructed test problems, we use Ackley Function [78] as their objective functions. Ackley Function can be written as:

$$
\begin{equation*}
f(x)=-a e^{-b \sqrt{\frac{1}{n} \sum_{i=1}^{n} x_{i}^{2}}}-e^{\frac{1}{n} \sum_{i=1}^{n} \cos \left(2 \pi x_{i}\right)}+a+e, \tag{116}
\end{equation*}
$$

where $a=20, b=0.2, n=2000$. Then, we use the gradients of 20 unconstrained optimization problems from $[1,39,61,78]$ as their constrained functions. In order to test the performance of the method for the different dimensions of constraints, we test the problems with few constraints ( $m \ll n$ such as $m=10, n=2000$ ), medium constraints ( $m \approx \frac{1}{2} n$ such as $m=1000, n=2000$ ) and many constraints ( $m \approx n$ such as $m=1999, n=2000$ ).

The termination conditions of three compared algorithms (Rcm, fmincon and SNOPT) are all set by

$$
\begin{align*}
& \left\|\nabla_{x} L\left(x_{k}, \lambda_{k}\right)\right\|_{\infty} \leq 1.0 \times 10^{-6}  \tag{117}\\
& \left\|c\left(x_{k}\right)\right\|_{\infty} \leq 1.0 \times 10^{-6}, k=1,2, \ldots \tag{118}
\end{align*}
$$

where the Lagrange function $L(x, \lambda)$ is defined by equation (4) and $\lambda$ is defined by equation (8). We test those 100 problems with $n \approx 1000$ to $n=2000$. Numerical results are arranged in Tables 1-6. Numerical results of 65 constrained optimization
problems from CUTEst [26] are arranged in Tables 1-3. And numerical results of 60 constructed constrained optimization problems are arranged in Tables 4-6. The computational time and the number of iterations of Rcm, fmincon and SNOPT are illustrated in Figure 1-2, respectively.

Since Algorithm 2 ( Rcm ) use Algorithm 1 (GCNMTr) to find an initial feasible point, we count its iterations including the iterations of GCNMTr (which are represented by $i t c_{G}$ ) and the self iterations of Rcm (which are represented by $i t c_{R}$ ) in Tables 1-6. SNOPT gives the number of solving QP subproblems (which are represented by "Major") and uses SQOPT solver [30] to find a solution of the QP subproblem. SNOPT also gives the total iterations of solving QP subproblems, which are represented by "ICTS". In order to ensure the evaluation objectivity, we count the number of solving QP subproblems and the total iterations of solving QP subproblems for SNOPT in Tables 1-6. fmincon only gives the number of solving QP subproblems and we denote them as "steps" in Tables 1-6.

In order to evaluate and compare those three methods (Rcm, fmincon and SNOPT) fairly, we also adopt the performance profile as a evaluation tool [16]. The performance profile for a solver is the (cumulative) distribution function for a performance metric, which is the ratio of the computing time of the solver versus the best time of all of the solvers as the performance metric. If the solver fails to solve a problem, we let its ratio be a bigger number such as 999 . Figure 3 is the performance profiles for three nonlinear programming solvers ( Rcm , fmincon and SNOPT). We also count the statistic number of failed problems and fasted problems computed by Rcm, fminincon and SNOPT. The statistical results are put in Table 7.

From Tables 1-6 and Table 7, we find that Rcm can solve most of test problems and few problems ( $6.4 \%$ ) can not be solved. However, fmincon fails to solve CUTEst problems about $\frac{28}{125}(22.4 \%)$ and SNOPT fails to solve problems about $\frac{21}{125}(16.8 \%)$. From Tables 1-6 and Figure 2, Figure 3, we find that the computational time of Rcm is significantly less than that of fmincon for most of test problems. From Tables 1-6 and Figure 1, we also find that the iterations of Rcm is significantly less than that of SNOPT for most of test problems. One of reasons is that Rcm only needs to solve a linear system of equations with dimension $n$ at every iteration. SQP needs to solve a linear system of equations with dimension $(m+n)$ when it solves a quadratic programming subproblem at every iteration (pp. 531-532, [65]) and involves about $\frac{2}{3}(m+n)^{3}$ flops (p. 116, [27]). The other reason is that Rcm uses the adaptive updating technique of the Jacobian matrix $A(x)$ of constraints $c(x)=0$ when it uses Algorithm 1 (GCNMTr) to find an initial feasible point. This technique can significantly save the computational time when GCNMTr solves an under-determined system of nonlinear equations [53]. We also find that SNOPT is significantly faster than Rcm on several test cases. The reason is due to the more gain of the complied language than that of the interpreted language, since SNOPT is written by C++ language (a complied language), and Rcm is written by MATLAB language (an interpreted language).

Table 7: The number of failed problems computed by Rcm, fmincon and SNOPT.

|  | Rcm | fmincon | SNOPT |
| :---: | :---: | :---: | :---: |
| The number of failed problems | 8 | 28 | 21 |
| The probability of failure | $\frac{8}{125}(6.4 \%)$ | $\frac{28}{125}(22.4 \%)$ | $\frac{21}{125}(16.8 \%)$ |
| The number of fasted problems | 48 | 3 | 72 |
| The probability of fasted problem | $\frac{48}{125}(38.4 \%)$ | $\frac{3}{125}(2.4 \%)$ | $\frac{72}{125}(57.6 \%)$ |

## 5 Conclusions

In this paper, we give the regularization continuation method with the trust-region updating strategy ( Rcm ) for nonlinear equality-constrained optimization problems. Namely, we use the inverse of the regularization quasi-Newton matrix as the preconditioner to improve its computational efficiency in the well-posed phase, and we use the inverse of the regularization two-sided projection of the Hessian matrix as the pre-conditioner to improve its robustness in the ill-conditioned phase. Since Rcm only solves a linear system of equations at every iteration and SQP needs to solve a quadratic programming subproblem at every iteration, Rcm is faster than SQP. Numerical results also show that Rcm is more robust and faster than SQP (the built-in subroutine fmincon.m of the MATLAB2020a environment [60,72] and the subroutine SNOPT [29,30] executed in GAMS v28.2 (2019) environment [23]). The computational time of Rcm is about one third of that fmincon.m for the large-scale problem. Therefore, Rcm is an alternating solver for equality-constrained optimization problems and the regularization continuation method is worthy to be explored further for inequality-constrained optimization problems and the orthogonal matrix constraint problems [84].

## Acknowledgments

This work was supported in part by Grant 61876199 from National Natural Science Foundation of China, Grant YBWL2011085 from Huawei Technologies Co., Ltd., and Grant YJCB2011003HI from the Innovation Research Program of Huawei Technologies Co., Ltd.. The authors are grateful to two anonymous referees for their comments and suggestions which greatly improve the presentation of this paper.

Conflicts of interest / Competing interests: Not applicable.
Availability of data and material (data transparency): If it is requested, we will provide the test data.

Code availability (software application or custom code): If it is requested, we will provide the code.
