Data Coding Means and Event Coding Means Multiplexed Over the 100BASE-T1 PMA Sublayer

Alexander Ivanov

Abstract—In this paper, we describe a way for enriching the 100BASE-T1 physical layer with an event transfer ability, based on the linguistic multiplexing approach.

Index Terms—Ethernet, linguistic multiplexing, multiplexing, time synchronization, synchronization, 100BASE-T1.

INTRODUCTION

F AST ETHERNET, type 100BASE-T1¹ [1] is a relatively new IEEE 802.3 physical layer much inherited from its predecessor, 1000BASE-T, but intended to work over a single unshielded twisted pair. Similar to the predecessor, it consists of just two vertically stacked sublayers, the 100BASE-T1 PCS on its top and the 100BASE-T1 PMA on its bottom.

Interfacing that underlying media, the 100BASE-T1 PMA² manipulates on pairs of PAM-3 symbols, therefore we say we employ some means that operates over a transport dictionary consisting of $3^2 = 3 \times 3 = 9$ transport words, two one-of-three possible letters in length each, see Table I, providing the user with a continuous, memory-less, sole-word-wide transfer channel sending one-of-nine word once a time period.

Similar to the 100BASE-T1 PCS³ that re-arranges the bits between the 4-bit nibbles on the service interface it provides on its top, i.e., the Media Independent Interface, and the 3-bit tuples on the intermediate interface it interacts with the PMA across, we operate on $9 \times 4 = 2 \times 6 \times 3 = 36$ -bit quantities collected over a sequence of nine consecutive nibbles to make up a pair of consecutive runs of six consecutive tuples each, see Table II, so solving the rate reconciliation problem.

In the rest of this paper, we use the linguistic multiplexing approach as it was developed up to in [2] as well as the baseprime scrambling concept as it is described in [3], leaving just one, see Table III, thing out of our current scope, assuming it somehow achievable in a reliable degree.

A manuscript of this work was submitted to IEEE Communications Letters November 26, 2022 and rejected as not being in the scope of the journal.

Please sorry for the author has no time to find this work a new home, peer reviewed or not, except of arXiv, and just hopes there it meets its reader, one

or maybe various, whom the author beforehand thanks for their regard. A. Ivanov is with JSC Continuum, Yaroslavl, the Russian Federation.

Digital Object Identifier 10.48550/arXiv.yymm.nnnnn (bundle).

¹Physical Layer for 100 Mbps networking, initially introduced as BroadR-Reach and then standardized in [1], operates in harsh environments, such as of automotive (in-vehicle) or industrial (in-cubicle) applications.

²Physical Medium Attachment sublayer, specified in [1], too, implements the 100BASE-T1 Medium Dependent Interface (MDI) transmitting three-level PAM symbols at a rate of $2/3 \times 100 = 66\frac{2}{3}$ million symbols/s.

³Physical Coding Sublayer, again specified in [1], implements the service interface (MII) operating at a rate of $1/4 \times 100 = 25$ million nibbles/s, and therefore reconciliates between the PMA (MDI) and its own (MII) rates.

TABLE I

Technique	REPRESENTATION (" < input ")	REPRESENTATION (" > input ")
Duration $(\Box = e_i)$	six word periods = 6×3 informatio	n bit times = ix word periods = 180 ns
Echo Pool	2·8 ⁶ = 524,288 samples required	12•8 ³ = 6,144 samples required

BIT GROUPS

We distinguish the four even + one spare + four odd MII bit groups (4-bit-long each), the six even + six odd PMA bit groups (3-bit-long each), and the one even + one odd halves (18-bit-long each) in a sequence of 36 consecutive information bits, all inter-arranged the respective way within the latter one we refer to as a super group, see Table II.

We assume that a delimiter, start-of-stream (SSD) or endof-stream (ESD), corresponds with a robust signaling,⁴ maybe out-of-band, see Table III, anyway taking place in the period of the earliest five even PMA bit groups of a super group.

⁴100BASE-T1 uses a comparatively long run of zero PAM-3 symbols.

This predefines the practicability limit when PRNG is updated once per a word, but if it is done once per twice that period, the limit could be doubled to about 515 s, and so on, depending on the number of the PRNG output values demanded per an echo round:

Echo Sa	Resulting Sub	set		
Longest Droop	DC Unb. Bound	Transits Count	Samples Within	App.
$\leq 7 \text{ or } \leq 7 \text{ or}$	± 7 0	- ≥ 3	various numbers	< NQ
≤8 / ≤8	± 8	≥2	530,432	= N _Q
> 8 / > 8	± 12	≥0	up to 9 ⁶ = 531,441	> N _Q

NOTE – Droop, in PAM-3 symbol time periods, is for the head / tail of an image. NOTE – DC unbalance bound, in unit dozes, is for any serial image in the subset. NOTE – Transits count, in PAM-3 level jumps, is per a serial image in the subset.

ECHO REPETITION MEANS

Following the synthesis flow developed in [2], we define the necessary echo multiplexing process the way we assume the most natural, so an echo multiplexing round, native or forced, see Table IV, fits exactly in and begins strictly at a half of a super group, i.e., occupies six consecutive transport words all related with either even or odd, but not of both anyway, PMA bit groups, as a single sample resulted from the round.⁵

As well, we restrict the multiplexing process so a delimiter occurs only during the even half of a super group, in contrast to a forced echo that occurs only during the odd half of a super group, thanks to that, these two never intersect in the stream, and a native echo occurs during any period which is free of a delimiter and a forced echo, repeating the respective process either (when it really is) due to a real necessity, or (otherwise) due to a handy generated cause,⁶ see Table V, eliminating the need in any other multiplexing scenarios.

By this, we preserve the behavior of the revised data transfer means, as the user observes it at the service interface, as much similar as possible with the behavior of the original physical layer,⁷ and simultaneously introduce an extra means intended to transfer an event, new to the original.

EVENT FIXATION MEANS

We distinguish up to $2 \times 6 = 12$ positions an event can be associated with, during a super group, in respect to the number of PMA bit groups comprising it, see Table V, that allows for an event fixation means to have a resolution of one event per a transport word and an accuracy of half a word.⁸

As it was described earlier, a super group—during which an event occurs—always conveys a forced echo sample that represents, among other information, the position of the event in that super group, in its odd half.

⁶In a form of an auxiliary bit value transferred per such a round, not visible to the PHY user at the MII, but still accessible indirectly, if needed.

⁷One difference lies in the implementation of an error propagation function, to convey up to one error per a frame as the 100BASE-T1 PCS does, that is not defined but still achievable in the proposed design, e.g., by truncation or extension of a frame to an odd number of MII nibbles.

⁸It can be used with a practically comfortable limitation, such as only nine positions ($9 < 12_{\max}$) in respect to the number of MII bit groups, instead of those of PMA, providing a proportionally coarser resolution of an event per a nibble and a lower accuracy of half the nibble period.

TABLE VIII Key Features of the Proposed Way

Parameter	Description
Coding Method, Technique	linguistic multiplexing, echo representation only
Coding Delay—Transmit	12 words = 360 ns = 100BASE-T1 TX delay limit
Coding Delay—Receive	24 words = 720 ns < 100BASE-T1 RX delay limit
Event Fixation Resolution	up to one event per a word = 30 ns [uncertainty \pm 15 ns]
Event Transmission Rate	up to one event per 60 words \approx 0.56 Mev/s
Physical (PMA) Line Code	three-level pulse-amplitude modulation (PAM-3)
Avg. (Max) Droop Duration	about 3 (16) PAM-3 symbols = about 45 (240) ns
Avg. Stream DC Unbalance	theoretically, zero over an infinite integration time
Avg. Number of Transitions	about 7.3 jumps per every 12 PAM-3 symbols

BASE-259 SUB-SCRAMBLER

It is the most complicated step on the proposed way and an integral part of the whole scrambler, see Table VI, synthesized following the approach described in [3], with some reasonable modification in pseudo random number generation.

Because the 100BASE-T1 PCS implements an excessive in the sense of the number of statistically independent binary values generated per a transport word period—PRNG, leveraged from its predecessor, the 1000BASE-T PCS, we use that excessiveness to generate base-259 pseudo random numbers, bringing an additional—however appropriate—inaccuracy but eliminating the need in a biasing anchor used in [3].

Based on this, we define a rule for the necessary base- $2^{>1}$ to base-259 conversion and then search for its optimal variant we finally select to ground the design on. Other details of the base-259 sub-scrambling are similar to the respective features of a general base-prime scrambling introduced in [3].

Compared to a base-2 sub-scrambler who seems trivial, the base-259 one seems very complex, but that complexity enables us to scramble on integral entities, i.e., echo samples, instead of individual bits, keeping the transferred stream consistent as much as possible,⁹ see Table VII.

CONCLUSION

We highlighted a way enriching the 100BASE-T1 physical layer with an event transfer ability, based on the redundancy, which is not so big but enough for, of the underlying transport means provided by its PMA sublayer. We tried to isolate all, or at least most of, the differences inside the PCS.

We hope that this way demonstrates interesting properties, see Table VIII, and, therefore, would be applicable in various mixed communication and synchronization tasks.

 $^9\mathrm{Assuming}\ N_Q = 259\cdot 2^{11} = 530,432,$ we consider the stream as a series of independent base- N_Q values, each scrambled as a whole, individually, by a modulo- N_Q unambiguously reversible operation, therefore, keeping its base the same both before and after the scrambling, see Tables VI and VII.

⁵There are $9^6 = 3^{12} = 531,441$ possible, distinguishable echo samples all together comprising the total echo pool, the native and forced echo pools consisting of $2 \cdot 8^6 = 524,288$ and $12 \cdot 8^3 = 6,144$ samples, respectively, are non-intersecting $(2 \cdot 8^6 + 12 \cdot 8^3 < 9^6)$ subsets of which.

Data Coding Means and Event Coding Means Multiplexed Over a 10BASE-T/Te MAU-like Entity

Alexander Ivanov

Abstract—We are seeking a way to supplement the 10BASE-T MAU with an event transfer ability, enabling either the linguistic multiplexing approach or an approach like PCS microframing. The way we suggest and describe in this paper is also applicable for the 10BASE-Te MAU and similar protocols.

Index Terms—Ethernet, linguistic multiplexing, multiplexing, like-a-Manchester, LaM, 10BASE-T, 10BASE-Te.

INTRODUCTION

ORIGINAL-speed Ethernet, type 10BASE-T per IEEE Std 802.3i-1990 [1] and its newer, energy-efficient variant, 10BASE-Te per IEEE Std 802az-2010 [2], both provide for a 10 Mbps Ethernet duplex connection over a dual-pair twisted-pair cable link, based upon a Manchester encoding variant as the line code they both implement to interact. Compared with its higher-speed successors, the corresponding physical layer looks very simple and consists only of the medium attachment unit (MAU) which embodies the respective physical medium attachment (PMA) sublayer as well as its exposed, compatible media dependent interface (MDI).

Inside of the 10BASE-T/Te PMA sublayer, there is no extra block-based or another-buffering coding means like inside of its successors, and therefore, generally speaking, such a PMA sublayer almost directly passes a signal—like CD0 and CD1 presented during transmissions of information bits—between the MDI under the bottom and the physical signaling (PLS) interface at the top of itself, respectively, merely conditioning the passed signal in its shape and power.

In this paper, we describe a way to construct a reciprocally multiplexed but independently operated data coding means and event coding means—in a form of some block-based physical coding sublayer (PCS)—feasible and stackable atop the PMA sublayer of the mentioned MAU, exploiting on the designated signaling transparency of the behavior the MAU demonstrates as well as on the known redundancy of the line code the MAU implements, contemporaneously.

RETHINKING THE 10BASE-T SIGNALING

Considering the Manchester encoding variant employed in 10BASE-T, see Table I, we conclude that the 10BASE-T MDI signal observed during transmission of information bits, i.e., a

Please sorry for the author has no time to find this work a new home, peer reviewed or not, except of arXiv, and just hopes there it meets its reader, one or maybe various, whom the author beforehand thanks for their regard.

period when the resulting waveform purely consists of the CD0 and CD1 signal shape repetitions, is sufficiently representable as some pulse train comprising consecutively and continuously running pulses varying in their polarity and duration, i.e., each being positive-or-negative while narrow-or-wide.

In support of our assumption made above, we see that the formal specification given in [1] also defines the MDI signal in the terms of narrow and wide pulses running in negative and positive polarities. Nominally, the duration of a wide pulse is exact one information bit time period, that is one tenth of a microsecond, i.e., 1/10 MHz = 100 ns, while the duration of a narrow pulse is just a half of the duration of a wide one, i.e., 1/20 MHz = 50 ns. Concerning the polarities, it is enough in our scope to say that a positive pulse and a negative pulse are

TABLE XIII Numerical Comparison

equal in absolute nominal amplitudes but opposite in relative directions designated to them.

Introducing a simple, "jump-and-keep" transport alphabet consisting of only two letters, J and K, we associate a narrow pulse with a JJ letter sequence and a wide pulse, respectively, with a JKJ sequence, definitely consuming exact one letter per a half of a bit time period—that corresponds to one letter per a narrow pulse versus two letters per a wide pulse—jointly by (a) going overlapped, or glued, with exact one letter, which is always J, and (b) shifted in phase by a quarter bit time period, compared with the original MDI pulse train, see Table II, and then conclude that it is both possible and sufficient to describe a 10BASE-T-compatible signaling in an abstract form of some continuous text written on the JK alphabet, barely preventing any run of two and more consecutive K's in such the text we also refer to as the letter transport stream.

Grounding on this concept, we now can design some likea-Manchester (LaM), block-based coding means built around an appropriate transport dictionary that consists exclusively of the so called valid serial images, i.e., the permitted words of a regular length measured as the number of letters within such a word, which are picked out of all the possible words of the selected length, written on the JK alphabet, to match with the compatibility criterion we established above.

POSSIBLE CODING SCHEMES

With the LaM approach enabled, there are many solutions becoming possible, see Table XIII, and the designer takes the choice among variants, balancing the implementation between its complexity and reliability, by (a) varying the length of and applicability (filtering) criterions for the valid serial images, see Tables III, VI, IX, and XI, that opts the data modulus and predefines the transport capacity available in such a condition, respectively, (b) picking between appropriate coding schemes and approaches like e.g. multiplexing, see Table IV, and (c) embedding and then tuning compensation measures like e.g. switched pages, see Table V, if it is necessary.

When the available transport capacity corresponding to the selected data modulus exceeds that modulus by at least a part of a bit, see Table VII, the designer reasonably could ground on the linguistic multiplexing model described in [3] and thus implement an appropriate coding means like the described in [4], that passes the data-related and event-related information sets implicitly intermixed via the echo cancellation procedure, see Tables III then IV, IX then X, and XI then XII.

When the available transport capacity exceeds the selected data modulus by at least one integral bit, see Table VIII, the designer could ground on a sort of PCS microframing like in 1000BASE-T1 or 10GBASE-T, considering every transmitted word a microframe, i.e., a time slot of a fixed, finite duration, smaller than the user frame, that conveys the data-related and event-related information sets explicitly separated.

CONCLUSION

Thereby, in this paper we highlighted a way to extend the 10BASE-T MAU with an event transfer ability, based on the transport redundancy of Manchester line code as well as on the behavior specificity of that MAU. Also, the proposed way could be applicable to other protocols being originated from or similar to the mentioned MAU.

Data Coding Means and Event Coding Means Multiplexed Over a 10BASE-T1S PMA-like Entity

Alexander Ivanov

Abstract—In this paper, we consider the 10BASE-T1S Ethernet physical layer, very redundant due to the 4B/5B over DME coding way the layer is based on, to extend it with a service new to it.

Index Terms—Ethernet, linguistic multiplexing, multiplexing, physical layer seamless preemption, preemption, physical layer time synchronization, synchronization, like-a-Manchester, LaM, line code balancing, balancing, 10BASE-T1S.

INTRODUCTION

O RIGINAL-SPEED Ethernet, type 10BASE-T1S¹ [1] is a comparatively fresh physical layer capable to operate over a single unshielded twisted pair of conductors located in a harsh environment like of automotive or industrial.

Due to the 4B/5B over DME coding scheme employed by the layer, we face a very excessive redundancy during the data transmission phase in the stream, of exact half the dictionary, if we can count on all the words within, see Table I.

For making this the case, we imply we can involve a set of out-of-band signaling symbols,² in a manner like it is done in [2] or [3], freeing every in-band symbol, i.e., any word present in the dictionary, of its initial purpose, see Table II.

In the rest of the paper, we describe a way developing the original physical layer in its services and features, all over its original duty and objective, grounding on the design approach we consider in the series of the following steps.

FROM CONVENTIONAL INTO PREEMPTABLE

Reexamining the original dictionary, see Table I again, we easily discern two non-intersecting and (therefore) orthogonal selections consisting of the same number, that is equal to half the dictionary, but of distinct words we gather guided by their common in the sense of their properties, see Table III.

Among the properties, as we think, the meaning of most of which is clear, there is just one, called the d.c. impact lasting time, that needs an extra explanation, see Table IV.

We connect one of the selections with the sub-stream which is responsible for transferring the preemptable payload in the multiplexed stream during the data transmission phase.

Recalling the fate of submission of many prior works to the peer reviewed journal, such a try with this one also promises no chance, probably.

Please sorry for the author has no time to find this work a new home, peer reviewed or not, except of arXiv, and just hopes there it meets its reader, one or maybe various, whom the author beforehand thanks for their regard.

A. Ivanov is with JSC Continuum, Yaroslavl, the Russian Federation.

	J J J J J J J J J J K J K J J J K J K J				
SILENCE	1111111111	10J-0K	=0	_/_	L [=0] L

Consequently, we connect the rest of the selections with the sub-stream which is responsible for transferring the preempting, express payload in the same multiplexed stream.

Because the selections, preemptable and express, are completely orthogonal to each other, we can find a set of allowable transits between them, easily, distinguishably, unambiguously, and then establish a stream preemption process we reasonably consider seamless, see Tables V and VI, respectively.

Based on the spoken above, we collect and then expose the requirements specifying an appropriate design we further will search for, to update the original one, see Table VII.

¹Allows for 10 Mbps operation in the full duplex mode, in the half duplex mode using the original, CDMA/CD-supporting MAC, and in the half duplex mode using the newly introduced, advanced, PLCA-supporting MAC, enabled over two pairs, one pair, and one pair of media, respectively, see [1].

²In the scope of a given ME (f_0) signal, including a differential option, as the considered in-band signaling procedure, meeting any ME ($f_0/2$) symbol causes an encoding violation, but such a violation is very reliably detectable and distinguishable as out-of-band, and thus usable, see [2] and [3].

TABLE II Implied Signaling Routine

$Phase \to$	Idle	Start-of-Stream signaling sequence	Management Commands	Payload (Data)	End-of-Stream signaling sequence	Idle
Encoding Type Modulation	f or Hi-Z	$DME(f_0/2)$	in-band DME (f ₀)	$DME(f_0 = 1/\tau_0)$	$DME(f_0/2)$	0Vdiff or Hi-Z
NOTE – Mgmt. cmds are optional.	0Vdiff	τ ₀ is payload	letter time, s	, thus f ₀ is payload	letter rate, Hz	0Vdif

FROM MANCHESTER INTO LIKE-A-MANCHESTER

We replace the original line code option, that was of DME, with its advanced substitute, that will be of LaM [4], priorly considering the original dictionary a set of J–K-written, quasi base-21 words [5], see Table I again, and next describing the underlying framework compactly [6], see Table VIII.

Using the same description basics, we construct the substituting framework, now LaM-related, aimed to preserve all the sensible properties of the original coding, see Table VII again, as well as to expand over the original performance, palpably, see Table IX and briefly the tables mentioned in Table X.

Given a length expressed in letters, each of those should be either J or K [4], we construct a set of transport words, each of that length as well as of those properties, also considering the words quasi base-21 [5], based on the renewed framework we also manipulate compactly [6], see Table XI.

FROM DETERMINISTIC INTO PROBABILISTIC

Applying the renewed framework with a word length in the scope of the search, we can receive up to four sets of such the words, distinct in their patterns and thence orthogonal in their contents, which are, however, so different in how they behave when sequenced, see Tables XII, XIII, and XIV.

Gathering over those unequal word sets, we obtain a couple of two supersets, or pages, also unequal because so purposed, one to maximize the effective size of the overall coding space while another to compensate during sequencing, then inscribe them into an appropriate or given scrambling space, balancing them via bubbling [7], see Tables XV, XVI, and XVII.

Mutually balanced, the two pages, maximizing and compensating, comprise the transport dictionary of the coding option, which we consider and tune, if and while necessary, matching between the corresponding per-*i*-th-letter-period probabilities, as close as it is possible, see Tables XVIII and XIX.

As the result of all the mentioned above, we reach a closely matched, highly balanced state of the design whose dictionary reflects a coding space variable in time, finitely and discretely, but probabilistically, see Tables XX, XXI, and XXII.

FROM TRANSPARENT INTO MULTIPLEXED

The probabilistic side of the current, n-th-word-time-period transport capacity, inherent for such a design, leads us to use a sort of time division multiplexing, shaping the characteristics of a design as dependent on those of the words the dictionary of that design consists of, see Tables XXIII and XXIV.

CONCLUSION

So, we described a way, compatible with and operable over the 10BASE-T1S PMA sublayer as well as similar ME-based protocols, that enables a LaM-renewed data transfer channel, variable or constant in its bit rate,³ see Table XXV.

Compared to the ME-based original, a LaM-based channel demonstrates a higher performance, whose extra part is usable in a manner backing a new service, an improved feature, or a combination thereof, see Tables XXVI and XXVII.

Thus, exactly the performance of a renewed channel in the first place among the sensitive requirements, including those of balancing, too, restricts the choice of an appropriate design providing such the channel, see Table XXVIII.

Implementing a suitable design, one could resolve a coding means based on the linguistic multiplexing approach, matured since [8], operating atop the corresponding channel directly or indirectly, see Tables XXIX and XXX, respectively.

³Primarily, we assume we design a VBR channel based upon the following probabilistic model opting the next page in the implicit favor of page A:

$$\begin{cases} p(\mathbf{A}) = p(\mathbf{A}) \times p(\cdots \mathbf{J}/\mathbf{A}) + p(\mathbf{B}) \times p(\cdots \mathbf{J}/\mathbf{B}) \\ p(\mathbf{B}) = p(\mathbf{A}) \times p(\cdots \mathbf{K}/\mathbf{A}) + p(\mathbf{B}) \times p(\cdots \mathbf{K}/\mathbf{B}) \end{cases}$$

however, when $\beta = \delta = 0$, we imply a CBR channel based upon the different model that, doubly oppositely, opts in the very explicit favor of page B:

 $\left\{ \begin{array}{rrr} p(\mathbf{A}) &=& p(\mathbf{A}) \times p(\cdots \mathtt{K}/\mathbf{A}) &+& p(\mathbf{B}) \times p(\cdots \mathtt{J}/\mathbf{B}) \\ p(\mathbf{B}) &=& p(\mathbf{A}) \times p(\cdots \mathtt{J}/\mathbf{A}) &+& p(\mathbf{B}) \times p(\cdots \mathtt{K}/\mathbf{B}) \end{array} \right.$

preserving all the rest principles we propose to balance a channel we design, via defining its respective properties, for both the models the same.

Data Coding Means and Event Coding Means Multiplexed Over the 10BASE-T1L PMA Sublayer

Alexander Ivanov

Abstract—In the paper, we modify the 10BASE-T1L Ethernet physical layer redundant, due to the 4B3T encoding the layer is based on, sufficiently to extend it with a new service.

Index Terms—Ethernet, linguistic multiplexing, multiplexing, physical layer seamy preemption, preemption, physical layer time synchronization, synchronization, 10BASE-T1L.

INTRODUCTION

O RIGINAL-SPEED Ethernet, type $10BASE-T1L^{1}$ [1] is a long-reach (~ 1000 m) physical layer capable to operate over a fieldbus-gauged twisted pair of conductors located in a harsh environment like of automotive or industrial.

The complete 10BASE-T1L Physical Layer is built around those two vertically stacked sublayers, 10BASE-T1L PCS and 10BASE-T1L PMA, assigned its physical coding and physical medium attachment sublayers, correspondingly.

That 10BASE-T1L PCS employs the 4B3T coding scheme to convert in between the stream of nibbles of bits, present on the PHY service interface, and the stream of triplets of ternary symbols, present on the PMA service interface.

That 10BASE-T1L PMA sublayer throws for every ternary symbol with a PAM-3 signaling level, thus, we say we practice a three-letter-size transport alphabet to next record on it a set of three-letter-long transport words, consequentially.

To keep the physical signal in the line dc-balanced, that set, or the whole transport dictionary, is divided into four distinct but intersecting subsets, or pages, as the ground for the means bounding the current running disparity of the stream.

In this paper, we discuss a bunch of ways intended to reach a multiservice layer design, whose underlying coding means will be compatible with the 10BASE-T1L initial duty, as well as operable over the 10BASE-T1L PMA sublayer.

THE GROUND BEHIND ANY POSSIBLE WAY

Given with the disparity-addressed behavior of the original coding means, as it was mentioned earlier, and further based on the linguistic multiplexing approach, as it was developed up to in [2] and [3], we refine the transport dictionary, during that, consider every its subset a page, either small or large, of either 16 or 18 words, respectively, see Table I.

Please sorry for the author has no time to find this work a new home, peer reviewed or not, except of arXiv, and just hopes there it meets its reader, one or maybe various, whom the author beforehand thanks for their regard.

A. Ivanov is with JSC Continuum, Yaroslavl, the Russian Federation.

Digital Object Identifier 10.48550/arXiv.yymm.nnnnn (bundle).

¹Allows for 10 Mbps operation in the (true) full duplex mode, see [1].

TABLE I MULTIPAGED TRANSPORT DICTIONARY

Ρ.	Set	Transport Words in ^(P) M	$\underbrace{(P)}{N_{C}} \underbrace{(P)}{N_{R}} \underbrace{(P)}{N_{E}} \underbrace{G}$	CD Applicable
1	⁽¹⁾ M	$^{(1)}m_0 \cdots {}^{(1)}m_{15}$	16 — —	— @ Σdc = 1
2	⁽²⁾ M	${}^{(2)}m_0\cdots{}^{(2)}m_{15},{}^{(2)}m_{16},{}^{(2)}m_{17}$	16 + 2 = 18	2 ¹ @ Σdc = 2
3	⁽³⁾ M	${}^{(3)}m_0 \cdots {}^{(3)}m_{15}, {}^{(3)}m_{16}, {}^{(3)}m_{17}$	16 + 2 = 18	2 ¹ @ Σdc = 3
4	⁽⁴⁾ M	${}^{(4)}m_0 \cdots {}^{(4)}m_{15}$	16 — —	— @ Σdc=4

TABLE II Current Page Content

Page	Context	Scope	Accessible Words	Multiplexing	Ev. Flags
P(<i>n</i>)	$\Sigma dc = P(n)$	(P)M -	$m_0 \cdots m_{15}, m_{16}, m_{17}$	POSSIBLE impossible	up to two —

TABLE III CODING SPACES

Space	Size = Σ Reps. of m's	Reps. of m_0	Reps. of m_1	Reps. of m ₂	• • •
Plain	9, 12, 16, or 18	up to once	up to once	up to once	•••
Cipher	always 2 ⁵ = 32	R(m₀)	R(m1)	R(m ₂)	

TABLE IV STREAM SCRAMBLING SCHEME

Space	Randomity Source	Bits Used	Bit Aliases	Scrambling Scope
Cipher	10BASE-T1L PRNG	Sy _n [0:4]	s _n [0] to s _n [4]	Regular Data Only

TABLE V Time Memo

PHY Protocol	MII Bit Time	Transport Letter Time	Word (Nibble) Time
10BASE-T1L	BT = 100 ns	1/f₀ = ⅓⋅BT = 133⅓ ns	$T_{\rm w} = 4.{\rm BT} = 400 {\rm ns}$

In the scope of the currently processed page, be it small or large, we operate on its words in a uniform manner, so being aware only of its size, i.e., the number of distinct words within that page, not of their certain definition, see Table II.²

Because the current page varies in time probabilistically, so does its size, too, necessitating us to design a coding measure capable to operate on a transmission channel characterized by a probabilistically variable word (bit) rate.

²Denoted by n (or t) is the current word (or letter) time period index.

Recalling the fate of submission of many prior works to the peer reviewed journal, such a try with this one also promises no chance, probably.

Considering since now for further the regular transmission only,³ we define all the necessary coding spaces, see Table III, some plain of different sizes and some cipher of the same size equal to the single size of the scrambling space, see Table IV, assuming here that a cipher space, characterized by the single, nominal size, is a mapping of some corresponding plain space, characterized by its effective size, being bubbled (up) to match with the size of the former, like it is done in [4], i.e., between the base-32 space of the scrambler, seen in time, see Table V, and an any-base coding space, like it is done in [5].

Thus, the definition of the spaces stands behind the certain transport dictionary, inherited from and then enlarged over the original 10BASE-T1L one, we use to establish a multiservice coding means, along other, preserving the disparity-addressed behavior of the progenitor, see Table VIII first in conjunction and then in comparison with Table VI,⁴ respectively.

Among a lot of variants of such the definition, possible and suitable, we select out just one, arbitrarily to some extent and therefore subjectively, which itself is generic, transparent, and clear, all in the scope of our discussion, of course, as well as, the same time, whose properties are very close to the original, see Table IX in comparison with Table VII.

⁴Data binary values and their symbols are as they are after scrambling.

³Regular data quantities are of those in modes SEND_N and SEND_I.

and pre-fetching the incoming data nibbles of the same periods $ \begin{array}{c c} \hline Effective \\ Echo Content \\ \hline \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\$	Tramsmit the result of that try	Perform a mocking echo round (see below)
$\frac{6}{n_{e}} \frac{\log_{2}E}{k} \stackrel{<\infty}{=} \frac{1}{n_{D}} \qquad $	then $n \leftarrow n + 6$	then $n \leftarrow n + 1$

TABLE XII Mocking Echo Cancellation Routine Compatible With Multiservice Operation

n _e ×	: k :	= <i>n</i> _D	Input Echo	One Round Depiction	Output Echo	Functional Equivalent
1	~	~	1/E -	$\rightarrow E/1 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 1/E$	→ 1/E	Delay by log₂E bit times

TABLE XIII Echo Cancellation Area Available During Multiservice Operation

Room Potentially Feasible \rightarrow	Pr.+SFD of This Frame	IFG Next to This Frame
Room Size (minus Cl. 146 delim.)	up to 64 (48) bit times	up to 96 (80) bit times

Among other, we do not restrict on the multiservice means to use the original delimitation, see Table X, or not.

Among other, we, however, restrict on that means to use a common pattern for any event insertion, see Table XIV briefly in conjunction with Table VIII again.⁵

THE EXOTIC WAY

Insertion of an event, see Table XIV briefly again, generates an echo, see Tables XV, XVI, and XVII briefly, every time it is invoked by the coding means operating on the transmission channel, and, for the return, causes on the means to somehow neutralize that echo, e.g., attempting to perform a line of echo multiplexing rounds really canceling the echo, that in our case may be endless in time, however, see Table XI.

 ${}^{5}R_{n-1}$ numbers are applicable only in the case of an event flag at n.

TABLE XIV Broadened Transport Dictionary Valid During Regular Multiservice Event Insertion Phase

Space	=1	Δdc	=2	Δdc	=3	∆dc	=4	Δdc	Assembly
R _{n-1}	m₁÷m9	+1/+2	m ₀ ÷m ₁	1=0/+1	$m_0 \div m_{11}$	=0/-1	m₁÷m9	-1/-2	fade-in

Cl. 146 delim.	fade-in at n−1 + flag at n	Ev. Disp. Bit	2 ⁸	single/ $(.5/f_0)^{\overline{8}}_{\overline{8}}$
Cl. 146 delim.	fade-in + flag at n + meta	Ev. Disp. Bit	2>8	≥ single/BT
Cl. 146 delim.	fade-in + flag at n + meta	Ev. INFO Bit	2>8	≥ various/BT

TABLE XVI Multiservice Implementation Alternatives Addressing Immediate Payload Preemption Challenges

Approach	Ncos	N _R @ flag	Е	Comment
Cl. 146 delim. + flag at n	≤3	CoS Index	220	4th period acts as fade-in
Cl. 146 d. + fade-in + flag	> 3	CoS Index	224	explicit fade-in assembly
fade-in at <i>n</i> −1 + flag at <i>n</i>	≤9	SSD/ESD	28	$\max N_{Cos} = \min \{9, 12\}$
fade-in + flag at n + meta	any	SSD/ESD	2>8	meta at n+1, +2, +3, etc.

TABLE XVII Multiservice Implementation Alternatives Addressing Simultaneous Heterogeneous Challenges

Data Framing	Sync Carrier	Sync Signal	Ncos	Resolution	Е
Cl. 146 d. +FF ⋟	{ fade-in + flag	pulse per span	= 2	≈ half/BT	2 ²⁴
Cl. 146 d. +FFM	.≫{ Fi + Fl + meta	short message	> 2	≥ half/BT	2>24
fade-in + flagsar	^{ne} fade-in + flag	pulse per span	= 2	= single/ T_w	28
Fi + Fl + metasar	^{ne} Fi + FI + meta	short message	> 2	$>$ single/ T_w	2>8

Due to the obvious reason, a hopeful echo will be very rare and supported by a mocking one, see Table XII, for the most of time, therefore all we can securely count on is the available echo neutralization budget (area), see Table XIII.

However, if the real echo cancellation is our goal, it causes the use of something else besides a mocking echo.

We consider such a design of a multiservice coding means as being implemented the exotic way, i.e., unrealistic.

THE PROGRESSIVE WAY

A multiservice may include a time synchronization service, characterized by a basic resolution, see Table XV, and a seamy preemption one, characterized by a set of classes of service,⁶ see Table XVI, both the same time, see Table XVII.

⁶A modern IEEE 802.1D/Q bridge supports for up to 8 traffic classes.

TABLE XX LINGUISTIC MULTIPLEXING CHARACTER

Technique \rightarrow	Substitution	Representation	
Application Subjects	any extra delimiters, event assemblies, mocking echo	bit shift, when $E \mod 4 \neq 0$ nothing, when $E \mod 4 = 0$	

We consider such a design of a multiservice coding means as being implemented the progressive way.

THE CONSERVATIVE WAY

A multiservice may include just one extra service over the original 10BASE-T1L duty, i.e., either of time, see Table XV again, or of data, see Table XVI again, but not both the same time, that simplifies the underlying coding means.

Anyway, at the heart of that service lies an event insertion pattern, see Table XIV, performing solo, or accompanying to the original delimitation, see Table X again, the proper choice of which is made in each particular case, carefully.

Anyway, the side effect of an event insertion is the echo it generates—accumulated with every event—we deal every next period with by a mocking round having the natural limits on its use within the frame, see Tables XII and XIII again.

With or without the delimitation, any event pattern consists at least of two assemblies, see Table XIV again, inserted into the multiplexed stream during the corresponding multiservice operation, see Table XVIII (example with delimitation).⁷

With or without the delimitation, any coding scheme results in reasonable coding delays, see Table XIX, whose variations, however, show as a little as no effect on the complexity of the underlying multiplexing process, see Table XX.

We consider such a design of a multiservice coding means as being implemented the conservative way.

CONCLUSION

In this paper, we discussed a bunch of ways enriching the functionality of the 10BASE-T1L PCS,⁸ all having the same ground, i.e., linguistic multiplexing applied over a dictionary of sufficient and redundant pages, behind them.

Among the ways, only the exotic one seems pure scientific, but interesting and important in theory, while the rest two are realistic enough to be implemented in practice.

Among the two, the progressive way introduces a synchronization service and a preemption service, both into and over the original duty of the considered Ethernet protocol.

Among the two, too, the conservative way limits the design with a single extra service enabled over the original duty.
