# $(\varepsilon, \delta)$-QUASI-NEGATIVE CURVATURE AND POSITIVITY OF THE CANONICAL BUNDLE 

KYLE BRODER AND KAI TANG

#### Abstract

A recent theorem of Diverio-Trapani and Wu-Yau asserts that a compact Kähler manifold with a Kähler metric of quasi-negative holomorphic sectional curvature is projective and canonically polarized. This confirms a long-standing conjecture of Yau. We consider the notion of $(\varepsilon, \delta)$-quasi-negativity, generalizing quasi-negativity, and obtain gap-type theorems for $\int_{X} c_{1}\left(K_{X}\right)^{n}>0$ in terms of the real bisectional curvature and weighted orthogonal Ricci curvature. These theorems are also a generalization of that results in [34] by Zhang-Zheng and in [11] by Chu-Lee-Tam.

## 1. Introduction

The Wu -Yau theorem $[9,26,16,27,28,25]$ asserts that a compact Kähler manifold with negative holomorphic sectional curvature is projective and canonically polarized. In particular, the canonical bundle $K_{X}$ is ample and there is a unique invariant Kähler-Einstein metric [1,31]. Diverio-Trapani [15] relaxed the strict negativity of the holomorphic sectional curvature to quasi-negativity (non-positive everywhere and negative at one point). The crux of the argument is the positivity of the top intersection number

$$
\begin{equation*}
\int_{X} c_{1}\left(K_{X}\right)^{n}>0 . \tag{1.1}
\end{equation*}
$$

Indeed, from [14, Theorem 0.5], (1.1) implies that the canonical bundle $K_{X}$ is big if we assume that $K_{X}$ is nef. Hence, $X$ is Moishezon, and by Moishezon's theorem [19], $X$ is projective and of general type. A projective manifold of general type with no rational curves has ample canonical bundle (see [15, Lemma 2.1] or [12, p. 219]).

Key words and phrases. Hermitian manifolds, Kähler manifolds, Wu-Yau theorem, hyperbolic complex manifolds, ample canonical bundle, holomorphic sectional curvature, real bisectional curvature, Moishezon manifolds, manifolds of general type.

The first named author was supported by the Australian Government through the Australian Research Council's Discovery Projects funding scheme (project DP220102530). The second named author was supported by National Natural Science Foundation of China (Grant No.12001490).

In their recent work, Zhang-Zheng [34] considered a natural notion of almost quasinegative holomorphic sectional curvature and extended these theorems to compact Kähler manifolds of almost quasi-negative holomorphic sectional curvature. They also obtained a gap-type theorem for the inequality $\int_{X} c_{1}\left(K_{X}\right)^{n}>0$ in terms of the holomorphic sectional curvature on compact Kähler manifolds. We will extend these results of Diverio-Trapani [15] and Zhang-Zheng [34] to the Hermitian category. We remind the reader that for non-Kähler Hermitian metrics, the holomorphic sectional curvature is naturally replaced by the real bisectional curvature

$$
\operatorname{RBC}_{\omega}(\xi):=\frac{1}{|\xi|^{2}} \sum_{i, j, k, \ell} R_{i \bar{j} k \bar{\ell}} \xi^{i \bar{j}} \xi^{k \bar{\ell}}
$$

where $\xi$ is a non-negative $(1,1)$-tensor. The real bisectional curvature was introduced by Yang-Zheng [30] in a frame-dependent manner. The above definition is also due to Lee-Streets [17], where it is referred to as the 'complex curvature operator'.

When the metric is Kähler (or, more generally, Kähler-like [29]), the real bisectional curvature is equivalent to the altered holomorphic sectional curvature formally defined in [8], which is comparable to the familiar holomorphic sectional curvature in the sense that they always have the same sign. In general, however, the real bisectional curvature is stronger than the holomorphic sectional curvature. It is not strong enough, however, to dominate the Ricci curvatures (see [30]). For a discussion of these curvatures for connections more general than the Chern connection, namely, the Gauduchon connections, we invite the reader to see [6].

To state the main results, we introduce the following terminology (building from [34]): For a positive constant $\delta>0$ and a non-empty open set $\mathcal{U} \subset X$ we say that a Hermitian metric $\eta$ has $(\varepsilon, \delta)$-quasi-negative real bisectional curvature (relative to $\mathcal{U}$ ) if there is a sufficiently small $\varepsilon>0$ such that $\mathrm{RBC}_{\eta} \leq \varepsilon$ on $X$ and if $\mathrm{RBC}_{\eta} \leq-\delta$ on $\mathcal{U}$. For positive constants $\delta_{1}, \delta_{2}>0$, we say that a Hermitian metric $\eta$ on a compact Kähler manifold $(X, \omega)$ is (i) $\delta_{1}$-bounded if there is a smooth function $\psi: X \rightarrow \mathbf{R}$ such that $\eta \leq \delta_{1} \omega+d d^{c} \psi$, and (ii) $\delta_{2}$-volume non-collapsed on an open set $\mathcal{U} \subset X$ if $\eta^{n} \geq \delta_{2} \omega^{n}$. If a Hermitian metric is both $\delta_{1}$-bounded and $\delta_{2}$-volume non-collapsed, we say that $\eta$ has $\left(\delta_{1}, \delta_{2}\right)$-bounded geometry.

The first main theorem of the present manuscript is the following:

Theorem 1.1. Let $X$ be a compact Kähler manifold. Suppose there is a Hermitian metric $\eta$ with $\left(\delta_{1}, \delta_{2}\right)$-bounded geometry and $(\varepsilon, \delta)$-quasi-negative real bisectional
curvature. Then

$$
\int_{X} c_{1}\left(K_{X}\right)^{n}>0
$$

If one further assumes that $K_{X}$ is nef, then $K_{X}$ is big and $X$ is projective.
The above theorem is a result in this direction that does not require the curvature of the Hermitian metric to have a sign. There are also many interesting results in [32, 33, 34, 23] without assuming a pointwise signed curvature condition. Further, let us emphasize that although the $\delta_{1}$-boundedness property is pointwise, it can be interpreted as a bound on the Bott-Chern class represented by the metric, not at the level of the metric. On the other hand, $\delta_{2}$-volume non-collapsing is a local weighted volume non-collapsing condition; for instance, it holds if $\eta^{n} \geq \delta_{2} \omega_{0}^{n}$ on $\mathcal{U}$.

Given the perplexing relationship between the holomorphic sectional curvature and the Ricci curvature (c.f., [5]), one can attempt to interpolate between these curvatures by considering the following curvature constraint: In [7] (see also [11]), the authors introduced, for $\alpha, \beta \in \mathbf{R}$ the weighted orthogonal Ricci curvature

$$
\operatorname{Ric}_{\alpha, \beta}^{\perp}(v):=\frac{\alpha}{|v|_{\omega_{0}}^{2}} \operatorname{Ric}_{\omega_{0}}(v, \bar{v})+\beta \operatorname{HSC}_{\omega_{0}}(v),
$$

for a (1,0)-tangent vector $v \in T^{1,0} X$.
From Siu's resolution [22] of the Grauert-Riemenschneider conjecture, a compact Kähler manifold with quasi-negative Ricci curvature has big canonical bundle. On the other hand, the Diverio-Trapani [15] extension of the Wu-Yau theorem shows that a compact Kähler manifold with quasi-negative holomorphic sectional curvature has big canonical bundle. The following theorem shows that these results can be interpolated via the weighted orthogonal Ricci curvature, and more generally, extended to the $(\varepsilon, \delta)$-quasi-negative situation:

Theorem 1.2. Let ( $X, \omega$ ) be a compact Kähler manifold with $(\varepsilon, \delta)$-quasi-negative weighted orthogonal Ricci curvature for $\alpha, \beta \in \mathbf{R}_{\geq 0}$ with at least one positive. Then

$$
\int_{X} c_{1}\left(K_{X}\right)^{n}>0
$$

If one further assumes that $K_{X}$ is nef, then $K_{X}$ is big and $X$ is projective.
Theorem 1.2 also extends a result of Chu-Lee-Tam [11], where they showed that if a compact Kähler manifold $X$ has a Kähler metric of quasi-negative weighted orthogonal

Ricci curvature (for $\alpha, \beta \in \mathbf{R}_{>0}$ ), then $\int_{X} c_{1}\left(K_{X}\right)^{n}>0$.

An alternative means of interpolating between the holomorphic sectional curvature and the Ricci curvature was described by Ni [20]: The so-called $k$-Ricci curvature of a Kähler metric is the Ricci curvature of the $k$-dimensional holomorphic subspaces of $T^{1,0} X$. By making use of a result in [11], the method used to prove Theorem 1.1 and Theorem 1.2 also provides the following (see also [23]):

Theorem 1.3. Let $(X, \omega)$ be a compact Kähler manifold with $(\varepsilon, \delta)$-quasi-negative $k$-Ricci curvature. Then

$$
\int_{X} c_{1}\left(K_{X}\right)^{n}>0
$$

If one further assumes that $K_{X}$ is nef, then $K_{X}$ is big and $X$ is projective.
Acknowledgements. The first named author would like to thank his former Ph.D. advisors Ben Andrews and Gang Tian for their support and encouragement. He would also like to thank Simone Diverio, Jeffrey Streets, Finnur Lárusson, Ramiro Lafuente, and James Stanfield for many valuable discussions and communications. The authors would like to thank Yashan Zhang for his support, and for many invaluable discussions and suggestions.

## 2. Proof of Theorem 1.1

To show that $\int_{X} c_{1}\left(K_{X}\right)^{n}>0$, it suffices to obtain the estimate

$$
\begin{equation*}
\int_{X}\left(-\operatorname{Ric}_{\omega_{0}}\right)^{n}=(2 \pi)^{n} \int_{X} c_{1}\left(K_{X}\right)^{n}>0 \tag{2.1}
\end{equation*}
$$

Let $\rho: \mathbf{R} \rightarrow \mathbf{R}$ be the function defined by $\rho(t)=\frac{1}{n}$ for $t \leq 0$ and $\rho(t)=1$ for $t>0$. For the Hermitian metric $\eta$ in the statement of Theorem 1.1, let $\kappa_{\eta}: X \rightarrow \mathbf{R}$ be the function

$$
\kappa_{\eta}(x):=\rho\left(\max _{\left(\vartheta, v_{x}\right) \in \mathcal{F}_{X} \times \mathbf{R}^{n}} \operatorname{RBC}_{\eta}\left(\vartheta, v_{x}\right)\right) \cdot \max _{\left(\vartheta, v_{x}\right) \in \mathcal{F}_{X} \times \mathbf{R}^{n}} \operatorname{RBC}_{\eta}\left(\vartheta, v_{x}\right),
$$

where $\vartheta$ is a unitary frame (i.e., a section of the unitary frame bundle $\mathcal{F}_{X}$ and $v_{x} \in \mathbf{R}^{n}$ ).

Let us also introduce the notation

$$
\begin{equation*}
\mu_{\eta}:=\max _{x \in X} \max _{\left(\vartheta, v_{x}\right) \in \mathcal{F}_{X} \times \mathbf{R}^{n}} \operatorname{RBC}_{\eta}\left(\vartheta, v_{x}\right) . \tag{2.2}
\end{equation*}
$$

To establish (2.1), we will show that there are constants $\varepsilon, c_{3}, c_{4}>0$ such that

$$
\begin{align*}
\int_{X}\left(-\operatorname{Ric}_{\omega_{0}}\right)^{n} & \geq \int_{X}\left(n \delta_{1} \kappa_{\eta} \omega_{0}-\operatorname{Ric}_{\omega_{0}}\right)^{n}-c_{4} \varepsilon  \tag{2.3}\\
& \geq c_{3}-c_{4} \varepsilon \tag{2.4}
\end{align*}
$$

where $\varepsilon>0$ can be chosen such that $c_{3}-c_{4} \varepsilon>0$.

To this end, consider the twisted $\mathrm{Wu}-\mathrm{Yau}$ continuity method, given by the complex Monge-Ampère equation

$$
\begin{equation*}
\left(t\left(\omega_{0}+\delta_{1}^{-1} d d^{c} \psi\right)-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}\right)^{n}=e^{\varphi_{t}} \omega_{0}^{n} \tag{2.5}
\end{equation*}
$$

From the assumption of $\delta_{1}$-boundedness, we see that

$$
\begin{equation*}
\omega_{0}+\delta_{1}^{-1} d d^{c} \psi \geq \delta_{1}^{-1} \eta \tag{2.6}
\end{equation*}
$$

Set $\omega_{t}:=t\left(\omega_{0}+\delta_{1}^{-1} d d^{c} \psi\right)-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}$, allowing us to write (2.5) as

$$
\omega_{t}^{n}=e^{\varphi_{t}} \omega_{0}^{n}
$$

From (2.6), the metrics $\omega_{t}$ afford the lower bound

$$
\operatorname{Ric}_{\omega_{t}} \geq-\omega_{t}+t \delta_{1}^{-1} \eta
$$

We will make use of the following Schwarz lemma for holomorphic maps between Hermitian manifolds due to Yang-Zheng [30] (see also [21, 3, 4]):

Lemma 2.1. (Yang-Zheng). Let $f:\left(X, \omega_{g}\right) \rightarrow(Y, \eta)$ be a holomorphic map from a Kähler manifold to a Hermitian manifold. If there are constants $C_{1}, C_{2} \in \mathbf{R}$ such that $\operatorname{Ric}_{\omega_{g}} \geq-C_{1} \omega+C_{2} f^{*} \omega_{h}$ and $\mathrm{RBC}_{\eta} \leq \mu_{\eta}$, then

$$
\Delta_{\omega_{g}} \log \operatorname{tr}_{\omega_{g}}\left(f^{*} \eta\right) \geq-C_{1}+\left(-\mu_{\eta}+\frac{C_{2}}{n}\right) \operatorname{tr}_{\omega_{g}}\left(f^{*} \eta\right)
$$

Taking $f$ to be the identity map, $C_{1}=1$, and $C_{2}=t \delta_{1}^{-1}$ in Lemma 2.1, we have

$$
\begin{equation*}
\Delta_{\omega_{t}} \log \operatorname{tr}_{\omega_{t}}(\eta) \geq\left(-\mu_{\eta}+t\left(n \delta_{1}\right)^{-1}\right) \operatorname{tr}_{\omega_{t}}(\eta)-1 \tag{2.7}
\end{equation*}
$$

By the maximum principle,

$$
\begin{equation*}
\sup _{X} \operatorname{tr}_{\omega_{t}}(\eta) \leq \frac{n \delta_{1}}{t-\mu_{\eta} n \delta_{1}} \tag{2.8}
\end{equation*}
$$

For $t>n \delta_{1} \mu_{\eta}$, the estimate (2.8) is independent of $t$. As a consequence, the continuity method admits a smooth solution for $t>n \delta_{1} \mu_{\eta}$ (c.f., [25, 32]). Introduce the
potential $u_{t}:=\varphi_{t}+t \delta_{1}^{-1} \psi$. The crux of the argument is to estimate $\sup _{u} u_{t}$ from below, and $\sup _{X} u_{t}$ from above. Indeed, the constant $c_{3}$ in (2.4) is given by

$$
c_{3}:=\liminf _{t \rightarrow n \delta_{1} \mu_{n}} \int_{X} e^{u_{t}} \omega_{0}^{n},
$$

where $\mu_{\eta}$ is defined in (2.2). The positivity of $c_{3}$ demands $u_{t}$ to not be identically $-\infty$, while the finiteness of $u_{t}$ requires an upper bound on $\sup _{X} u_{t}$. Before obtaining the upper bound on $\sup _{X} u_{t}$, we first note that in contrast to the situations considered by Wu-Yau [27], Tosatti-Yang [25], and Diverio-Trapani [15], we do not have a metric with signed curvature. To handle the positive curvature contributions, we make use of Tian's $\alpha$-invariant [24] (see also [34]):

Proposition 2.2. (Tian's $\alpha$-invariant). Let $(X, \omega)$ be a compact Kähler manifold. There is a positive number $\alpha=\alpha(X,[\omega])$ depending only on $X$ and the Kähler class [ $\omega$ ] such that for any $\beta \in(0, \alpha)$ and any $u \in \mathcal{C}^{\infty}(X, \mathbf{R})$ with $\omega+d d^{c} u>0$ and $\sup _{X} u=0$, there is a constant $C_{\beta}=C_{\beta}(\omega)$ such that

$$
\int_{X} e^{-\beta u} \omega^{n} \leq C_{\beta}
$$

We now obtain an upper bound on $\sup _{X} u_{t}$ :
Lemma 2.3. For $t \in\left(n \delta_{1} \mu_{\eta}, 2 n \delta_{1} \mu_{\eta}\right]$, we have

$$
\begin{equation*}
\sup _{x \in X} u_{t}(x) \leq \log \left(2 n \delta_{1} \varepsilon+b_{0}\right)^{n} \leq \log \left(c_{0}+b_{0}\right)^{n} \tag{2.9}
\end{equation*}
$$

where $c_{0}>0$ is such that Tian's $\alpha$-invariant satisfies $\alpha\left(X, c_{0} \omega_{0}\right) \geq 2$, and $\varepsilon \leq$ $c_{0} /\left(2 n \delta_{1}\right)$.

Proof. Since $u_{t}=\varphi_{t}+t \delta_{1}^{-1} \psi$, (2.7) reads

$$
\begin{equation*}
e^{u_{t}-t \delta_{1}^{-1} \psi} \omega_{0}^{n}=e^{\varphi_{t}} \omega_{0}^{n}=\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} u_{t}\right)^{n} \tag{2.10}
\end{equation*}
$$

Since the metric $\omega_{0}$ is smooth, and $X$ is compact, there is some $b_{0} \geq 0$ such that

$$
\begin{equation*}
\operatorname{Ric}_{\omega_{0}} \geq-b_{0} \omega_{0} \tag{2.11}
\end{equation*}
$$

From (2.10), (2.11), and the fact that $\psi \leq 0$, at the point $x \in X$ where $u_{t}$ achieves its maximum, we have

$$
\sup _{x \in X} u_{t}(x) \leq \sup _{X}\left(t \delta_{1}^{-1} \psi+\log \frac{\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} u_{t}\right)^{n}}{\omega_{0}^{n}}\right) \leq \log \left(t_{0}+b_{0}\right)^{n}
$$

Since $t \leq 2 n \delta_{1} \mu_{\eta} \leq 2 n \delta_{1} \varepsilon$, this proves (2.9).

We now want to estimate $\sup _{u} u_{t}$ from below.

## Lemma 2.4.

$$
\begin{equation*}
\sup _{u} u_{t} \geq n \log (n)+\log \left(\frac{-\int_{u} \kappa_{\eta} e^{t\left(n \delta_{1}\right)^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n}}{\int_{X} \omega_{t}^{n}}\right) . \tag{2.12}
\end{equation*}
$$

Proof. Start by integrating (2.7) over $X$ with respect to the volume form $\omega_{t}^{n}$. By the divergence theorem,

$$
\begin{aligned}
\int_{X} \omega_{t}^{n} & \geq \int_{X}\left(-\kappa_{\eta}+t\left(n \delta_{1}\right)^{-1}\right) \operatorname{tr}_{\omega_{t}}(\eta) \omega_{t}^{n} \\
& \geq \int_{u}\left(-\kappa_{\eta}+t\left(n \delta_{1}\right)^{-1}\right) \operatorname{tr}_{\omega_{t}}(\eta) \omega_{t}^{n} \geq-\int_{u} \kappa_{\eta} \operatorname{tr}_{\omega_{t}}(\eta) \omega_{t}^{n}
\end{aligned}
$$

using the fact that $\left(-\kappa_{\eta}+t\left(n \delta_{1}\right)^{-1}\right) \operatorname{tr}_{\omega_{t}}(\eta)>0$. By the arithmetic-geometric mean inequality,

$$
\begin{align*}
-\int_{U} \kappa_{\eta} \operatorname{tr}_{\omega_{t}}(\eta) \omega_{t}^{n} & \geq-n \int_{u} \kappa_{\eta}\left(\frac{\eta^{n}}{\omega_{t}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n} \\
& =-n \int_{u} \kappa_{\eta}\left(\frac{\omega_{0}^{n}}{\omega_{t}^{n}}\right)^{\frac{1}{n}}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n} . \tag{2.13}
\end{align*}
$$

Using (2.10) in (2.13), we achieve the estimate

$$
\begin{align*}
\int_{X} \omega_{t}^{n} & \geq-n \int_{\mathcal{U}} \kappa_{\eta} e^{-\frac{1}{n}\left(u_{t}-t \delta_{1}^{-1} \psi\right)}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n} \\
& \geq-n e^{-\frac{1}{n} \sup _{\mathcal{u}} u_{t}} \int_{\mathcal{U}} \kappa_{\eta} e^{t\left(n \delta_{1}\right)^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n} \tag{2.14}
\end{align*}
$$

Then (2.12) follows from (2.14).
From the above lemma, it suffices to estimate

$$
\begin{equation*}
\frac{-\int_{u} \kappa_{\eta} e^{t\left(n \delta_{1}\right)^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n}}{\int_{X} \omega_{t}^{n}} \tag{2.15}
\end{equation*}
$$

from below. The following lemma gives an estimate for the numerator:

Lemma 2.5. There are positive constants $c_{1}, \delta_{2}>0$ such that

$$
\begin{equation*}
-\int_{u} \kappa_{\eta} e^{t\left(n \delta_{1}\right)^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n} \geq \delta_{2} \delta \int_{u} e^{u_{t}^{*}} \omega_{0}^{n} \geq \frac{c_{1} \delta_{2}^{\frac{1}{n}} \delta}{n} \tag{2.16}
\end{equation*}
$$

Proof. Let us write $u_{t}^{*}:=u_{t}-\sup _{X} u_{t}$, so that $\sup _{X} u_{t}^{*} \leq 0$. In this notation, (2.15) reads

$$
\begin{align*}
\frac{-\int_{u} \kappa_{\eta} e^{t\left(n \delta_{1}\right)^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n}}{\int_{X} \omega_{t}^{n}} & =\frac{-\int_{u} \kappa_{\eta} e^{u_{t}} e^{-\left(1-\frac{1}{n}\right) t \delta_{1}^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{0}^{n}}{\int_{X} e^{u_{t}} e^{-t \delta_{1}^{-1} \psi} \omega_{0}^{n}} \\
& =\frac{-\int_{u} \kappa_{\eta} e^{u_{t}^{*}} e^{-\left(1-\frac{1}{n}\right) t \delta_{1}^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{0}^{n}}{\int_{X} e^{u_{t}^{*}} e^{-t \delta_{1}^{-1} \psi} \omega_{0}^{n}} \tag{2.17}
\end{align*}
$$

Since $\psi \leq 0$, and $t \in\left(n \delta_{1} \mu_{\eta}, 2 n \delta_{1} \mu_{\eta}\right]$, we have

$$
\begin{align*}
-\int_{\mathcal{U}} \kappa_{\eta} e^{u_{t}^{*}} e^{-\left(1-\frac{1}{n}\right) t \delta_{1}^{-1} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{0}^{n} & \geq-\int_{\mathcal{U}} \kappa_{\eta} e^{u_{t}^{*}} e^{(1-n) \kappa_{\eta} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{0}^{n} \\
& \geq \delta \int_{\mathcal{U}} e^{u_{t}^{*}} e^{(1-n) \kappa_{\eta} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{0}^{n} \tag{2.18}
\end{align*}
$$

where the last inequality follows from the negative curvature estimate $\mathrm{RBC}_{\eta} \leq-\delta_{3}$ on $\mathcal{U}$. Let

$$
\begin{equation*}
c_{1}:=\inf \left\{\int_{u} e^{v} \omega_{0}^{n}: v \in \operatorname{PSH}_{\left(c_{0}+b_{0}\right) \omega_{0}}(X), \sup _{X} v=0\right\} . \tag{2.19}
\end{equation*}
$$

Then $c_{1}$ is a positive constant depending only on $\mathcal{U}$ and $\omega_{0}$. Since $\eta$ has $\left(\delta_{1}, \delta_{2}\right)$-bounded geometry, we have

$$
-\int_{\mathcal{U}} \kappa_{\eta} e^{u_{t}^{*}} e^{-(n-1) \mu_{\eta} \psi}\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{0}^{n} \geq \frac{\delta_{2}^{\frac{1}{n}} \delta}{n} \int_{\mathcal{U}} e^{u_{t}^{*}} \omega_{0}^{n} \geq \frac{c_{1} \delta_{2}^{\frac{1}{n}} \delta}{n} .
$$

From (2.18) and (2.19), this gives the desired lower bound for the numerator in (2.17).

We now complete the estimate for lower bound on $\sup _{u} u_{t}$ :
Lemma 2.6. There are constants $c_{1}, c_{2}, \delta_{1}, \delta_{2}>0$ such that

$$
\sup _{u} u_{t} \geq n \log (n)+\log \left(\frac{c_{1} \delta_{2} \delta}{c_{2}}\right) .
$$

Proof. For the denominator in (2.17), we will again use Tian's $\alpha$-invariant [24]. Indeed, first observe that, since $0<t \leq 2 n \delta_{1} \mu_{\eta} \leq c_{0}$, (2.6) implies

$$
c_{0} \omega_{0}+t \delta_{1}^{-1} d d^{c} \psi \geq t \omega_{0}+t \delta_{1}^{-1} d d^{c} \psi \geq t \delta_{1}^{-1} \eta>0
$$

In other words, $t \delta_{1}^{-1} \psi$ is $c_{0} \omega_{0}$-plurisubharmonic. Hence, since $c_{0}>0$ is chosen such that Tian's $\alpha$-invariant satisfies $\alpha\left(X, c_{0} \omega_{0}\right) \geq 2$, we have

$$
\begin{equation*}
\int_{X} e^{u_{t}^{*}} e^{-t \delta_{1}^{-1} \psi} \omega_{0}^{n} \leq \int_{X} e^{-t \delta_{1}^{-1} \psi} \omega_{0}^{n}=c_{0}^{-n} \int_{X} e^{-t \delta_{1}^{-1} \psi}\left(c_{0} \omega_{0}\right)^{n} \leq c_{2} \tag{2.20}
\end{equation*}
$$

for some constant $c_{2}>0$ depending only on $c_{0}$ and $\omega_{0}$. Combining (2.15), (2.17), (2.16), and (2.20), we see that

$$
\begin{equation*}
\frac{-\int_{U} \kappa_{\eta} e^{t\left(n \delta_{1}\right)^{-1}} \psi\left(\frac{\eta^{n}}{\omega_{0}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n}}{\int_{X} \omega_{t}^{n}} \geq \frac{c_{1} \delta_{2}^{\frac{1}{n}} \delta}{n c_{2}} . \tag{2.21}
\end{equation*}
$$

Inserting (2.21) into (2.12),

$$
\sup _{u} u_{t} \geq n \log (n)+\log \left(\frac{c_{1} \delta_{2}^{\frac{1}{n}} \delta}{n c_{2}}\right)
$$

We now complete the proof: Let $c_{4}>0$ be the constant such that

$$
\int_{X} \sum_{k=1}^{n}\binom{n}{k}\left(2 n \delta_{1} \varepsilon \omega_{0}\right)^{k} \wedge\left(-\operatorname{Ric}_{\omega_{0}}\right)^{n-k} \leq c_{4} \varepsilon
$$

Then

$$
\begin{aligned}
\int_{X}\left(2 \pi c_{1}\left(K_{X}\right)\right)^{n}=\int_{X}\left(-\operatorname{Ric}_{\omega_{0}}\right)^{n} & \geq \int_{X}\left(2 n \delta_{1} \varepsilon \omega_{0}-\operatorname{Ric}_{\omega_{0}}\right)^{n}-c_{4} \varepsilon \\
& \geq \lim _{t \searrow n \delta_{1} \mu_{\eta}}\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} u_{t}\right)^{n}-c_{4} \varepsilon \\
& =\lim _{t \searrow n \delta_{1} \mu_{\eta}} \int_{X} e^{u_{t}} e^{-t \delta_{1}^{-1} \psi} \omega_{0}^{n}-c_{4} \varepsilon \\
& \geq \liminf _{t \backslash n \delta_{1} \mu_{\eta}} \int_{X} e^{u_{t}} \omega_{0}^{n}-c_{4} \varepsilon \\
& =c_{3}-c_{4} \varepsilon
\end{aligned}
$$

Taking $\varepsilon \leq \min \left\{\frac{c_{3}}{2 c_{4}}, \frac{c_{0}}{2 n \delta_{1}}\right\}$ completes the proof.

Recall that a compact complex manifold $X$ is said to be Moishezon if $X$ is bimeromorphic to a projective manifold. Any compact complex manifold with a big line bundle $\mathcal{L} \rightarrow X$ is Moishezon, with the linear system $|\mathcal{L}|$ furnishing the bimeromorphic map. In particular, a compact complex manifold $X$ of general type (i.e., the canonical bundle $K_{X}$ is big) is Moishezon. In particular, we have:

Corollary 2.7. Let $(X, \omega)$ be a compact Kähler manifold with $\left(\delta_{1}, \delta_{2}\right)$-bounded geometry and $(\varepsilon, \delta)$-quasi-negative holomorphic sectional curvature. If one further assumes that $K_{X}$ is nef, then $X$ is of general type, and thus, in particular, Moishezon.

Moishezon's theorem [19] asserts that a Moishezon manifold that is Kähler, is projective. Further, from the recent developments in the minimal model program [2, Corollary 1.4.6], a Moishezon manifold without rational curves is projective. In particular, from [14, Theorem 0.5], we have the following:

Corollary 2.8. Let $X$ be a compact Kähler manifold endowed with a Hermitian metric of $\left(\delta_{1}, \delta_{2}\right)$-bounded geometry and $(\varepsilon, \delta)$-quasi-negative holomorphic sectional curvature. If one further assumes that $K_{X}$ is nef and $X$ is Kobayashi hyperbolic, then $X$ is projective with ample canonical bundle.

Remark 2.9. It would be interesting to further explore the role played by Tian's $\alpha$-invariant, given its place in algebraic geometry. Indeed, we remind the reader that Tian's $\alpha$-invariant is an asymptotic version of the log canonical threshold (see [24, 13, 10]).

## 3. Proof of Theorem 1.2

To see Theorem 1.2, we first prove a useful lemma by employing a method of $\mathrm{Li}-$ Ni-Zhu [18]. Let

$$
\lambda_{\omega_{0}}:=\max _{x \in X} \max _{v \in T_{x}^{1,0} X} \operatorname{Ric}_{\alpha, \beta}^{\perp}(v)
$$

Define

$$
\tau_{\omega_{0}}(x):=\rho\left(\max _{v \in T_{x}^{1,0} X} \operatorname{Ric}_{\alpha, \beta}^{\perp}(v)\right) \cdot \max _{v \in T_{x}^{1,0} X} \operatorname{Ric}_{\alpha, \beta}^{\perp}(v)
$$

where $\rho: \mathbf{R} \rightarrow\{n+1,2 n\}$ is a function with $\rho(s)=n+1$ for $s \leq 0$ and $\rho(s)=2 n$ for $s>0$.

Lemma 3.1. Let $\left(X^{n}, \omega_{0}\right)$ be a compact Kähler manifold. We consider the following complex Monge-Ampère equation for $\varphi_{t}$ :

$$
\begin{equation*}
\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}\right)^{n}=e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{0}^{n} \tag{3.1}
\end{equation*}
$$

(a) If $\lambda_{\omega_{0}} \geq 0$, then the solution $\varphi_{t}$ to equation (3.1) exists for $t \in\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha},+\infty\right)$;
(b) If $\lambda_{\omega_{0}}<0$, then the solution $\varphi_{t}$ to equation (3.1) exists for $t \in[0,+\infty)$.

Proof. We consider the following complex Monge-Ampère equation for $\varphi_{t}$ :

$$
\begin{equation*}
\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}\right)^{n}=e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{0}^{n} . \tag{3.2}
\end{equation*}
$$

if $t$ is large enough, then $t \omega_{0}-\operatorname{Ric}_{\omega_{0}}>0$. By the Aubin-Yau theorem [1, 31], there is a unique smooth solution $\varphi_{t}$ of (3.2) for $t \in(T,+\infty)$, where $T$ is the minimum existence time of $\varphi_{t}$. We assume Lemma 3.1(a) fails, i.e. $T>\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha} \geq 0$. Without losing generality, we only consider the $t \in(T, A]$, where $A$ is a fixed positive constant large enough. Set $\omega_{t}:=t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}$. Then for $t \in(T, A]$, we have

$$
\begin{equation*}
\omega_{t}=t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}>0 \tag{3.3}
\end{equation*}
$$

and (3.2) is equivalent to

$$
\begin{equation*}
\operatorname{Ric}_{\omega_{t}}=-\omega_{t}+t \omega_{0}-\frac{\alpha}{2 \beta} d d^{c} \varphi_{t} . \tag{3.4}
\end{equation*}
$$

To simplify notation we write the components of $\omega_{t}$ as $g_{i \bar{j}}$ and the components of $\omega_{0}$ as $h_{\alpha \bar{\beta}}$. Let $G=\operatorname{tr}_{\omega_{t}} \omega_{0}=\operatorname{tr}_{g} h$, from Lemma 2.1 we have

$$
\begin{equation*}
\Delta_{\omega_{t}} \log G \geq \frac{1}{G}\left(\operatorname{Ric}_{i \bar{j}}^{g} g^{i \bar{q}} g^{p \bar{j}} h_{p \bar{q}}-g^{i \bar{j}} g^{k \bar{l}} R_{i \bar{j} k \bar{l}}^{h}\right) \tag{3.5}
\end{equation*}
$$

By [18, Lemma 2.2], we get

$$
\begin{equation*}
\frac{1}{G} g^{i \bar{j}} g^{k \bar{l}} R_{i \bar{j} k \bar{l}}^{h} \leq \frac{\lambda}{2 \beta} G+\frac{\lambda}{2 \beta G}|h|_{g}^{2}-\frac{\alpha}{\beta} \operatorname{tr}_{g} \operatorname{Ric}^{h}+\frac{\alpha}{2 \beta G}\left(G \cdot \operatorname{tr}_{g} \operatorname{Ric}^{h}-\left\langle\omega_{h}, \operatorname{Ric}^{h}\right\rangle_{g}\right) . \tag{3.6}
\end{equation*}
$$

Choosing local coordinates such that $g_{i \bar{j}}=\delta_{i \bar{j}}, h_{i \bar{j}}=h_{i \bar{i}} \delta_{i j}$, then

$$
\begin{align*}
G \cdot \operatorname{tr}_{g} \operatorname{Ric}^{h}-\left\langle\omega_{h}, \operatorname{Ric}^{h}\right\rangle_{g} & =\sum_{i} \operatorname{Ric}_{\overline{i \bar{i}}}^{h}\left(\sum_{j} h_{j \bar{j}}-h_{i \bar{i}}\right)=\sum_{i}\left(\operatorname{Ric}_{i \bar{i}}^{h}\left(\sum_{j \neq i} h_{j \bar{j}}\right)\right) \\
& \leq \sum_{i}\left(t \cdot h_{i \bar{i}}+\sqrt{-1} \varphi_{t, i \bar{i}}\right)\left(\sum_{j} h_{j \bar{j}}-h_{i \bar{i}}\right)  \tag{3.7}\\
& =t G^{2}-t|h|_{g}^{2}+G \Delta_{g} \varphi_{t}-\left\langle d d^{c} \varphi_{t}, h\right\rangle_{g}
\end{align*}
$$

Here we used (3.3). Combining (3.6) and (3.7), we get

$$
\begin{align*}
\frac{1}{G} g^{i \bar{j}} g^{k \bar{l}} R_{i \bar{j} k \bar{l}}^{h} \leq & \frac{\lambda+\alpha t}{2 \beta} G+\frac{\lambda-\alpha t}{2 \beta} \frac{|h|_{g}^{2}}{G}-\frac{\alpha}{\beta} \operatorname{tr}_{g} \operatorname{Ric}^{h} \\
& +\frac{\alpha}{2 \beta} \Delta_{g} \varphi_{t}-\frac{\alpha}{2 \beta} \frac{1}{G}\left\langle d d^{c} \varphi_{t}, h\right\rangle_{g} \tag{3.8}
\end{align*}
$$

By using (3.4), we have

$$
\begin{align*}
\frac{1}{G} \operatorname{Ric}_{i \bar{j}}^{g} g^{i \bar{q}} g^{p \bar{j}} h_{p \bar{q}} & =\frac{1}{G}\left\langle\operatorname{Ric}^{g}, h\right\rangle_{g}=\frac{1}{G}\left\langle-g+t h-\frac{\alpha}{2 \beta} d d^{c} \varphi_{t}, h\right\rangle_{g} \\
& =\frac{1}{G}\langle-g+t h, h\rangle_{g}-\frac{1}{G} \frac{\alpha}{2 \beta}\left\langle\varphi_{t}, h\right\rangle_{g} \tag{3.9}
\end{align*}
$$

Combining (3.5), (3.8) and (3.9), we get

$$
\begin{align*}
\Delta_{\omega_{t}}\left(\log G-\frac{\alpha}{2 \beta} \varphi_{t}\right) \geq & -\frac{\lambda+\alpha t}{2 \beta} G-\frac{\lambda-\alpha t}{2 \beta} \frac{|h|_{g}^{2}}{G}+\frac{\alpha}{\beta}\left(\operatorname{tr}_{g} \operatorname{Ric}^{h}-\Delta_{g} \varphi_{t}\right) \\
& +\frac{1}{G}\langle-g+t h, h\rangle_{g} \tag{3.10}
\end{align*}
$$

If $\lambda \geq 0$, since $t>T>0, n|h|_{g}^{2} \geq G^{2},|h|_{g}^{2} \leq G^{2}$,

$$
\begin{equation*}
\Delta_{g} \varphi_{t}=n-t G+\operatorname{tr}_{g} \operatorname{Ric}^{h} \tag{3.11}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{1}{G}\langle-g+t h, h\rangle_{g}=-1+\frac{t}{G}|h|_{g}^{2} \geq-1 \tag{3.12}
\end{equation*}
$$

so we have

$$
\begin{equation*}
\Delta_{\omega_{t}}\left(\log G-\frac{\alpha}{2 \beta} \varphi_{t}\right) \geq\left(\frac{(n+1) \alpha t-2 n \lambda}{2 \beta n}\right) G-\left(\frac{\alpha n}{\beta}+1\right) \tag{3.13}
\end{equation*}
$$

Now we apply the maximum principle to get a uniform lower estimate of $\omega_{t}$. For any fixed $t \in(T, A]$, at the maximum point $x_{1}$ of the $\varphi_{t}$, we have $d d^{c} \varphi_{t} \leq 0$, so we can get

$$
\begin{equation*}
0<g=\left.\omega_{t}\right|_{x_{1}} \leq t \omega_{0}-\operatorname{Ric}_{\omega_{0}}\left(x_{1}\right) \tag{3.14}
\end{equation*}
$$

and

$$
\begin{equation*}
e^{\left(1+\frac{\alpha}{2 \beta}\right) \sup _{X} \varphi_{t}(x)}=e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}\left(x_{1}\right)} \leq \frac{\left.\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}\right)\right)^{n}}{\omega_{0}^{n}} \leq C \tag{3.15}
\end{equation*}
$$

where $C$ is independent of $t$. Hence $\varphi_{t}$ has a uniform upper bound, and we also get

$$
\begin{equation*}
\omega_{t}^{n} \leq C^{\prime} \omega_{0}^{n} \tag{3.16}
\end{equation*}
$$

Again applying maximum principle to $\log G-\frac{\alpha}{2 \beta} \varphi_{t}$. At the point $x_{2}$, where the maximum of $\log G-\frac{\alpha}{2 \beta} \varphi_{t}$ is attained, since $t>T>\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha} \geq 0$, by (3.13), we have that

$$
\begin{equation*}
G\left(x_{2}\right) \leq C^{\prime \prime} \tag{3.17}
\end{equation*}
$$

where $C^{\prime \prime}$ is also independent of $t$. We note that

$$
\begin{equation*}
G \cdot\left(\frac{\omega_{0}^{n}}{\omega_{t}^{n}}\right)^{\frac{\alpha}{2 \beta+\alpha}}=G \cdot\left(e^{-\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}}\right)^{\frac{\alpha}{2 \beta+\alpha}}=G \cdot e^{-\frac{\alpha}{2 \beta} \varphi_{t}} . \tag{3.18}
\end{equation*}
$$

So $\sup _{X} G \cdot\left(\frac{\omega_{0}^{n}}{\omega_{t}^{n}}\right)^{\frac{\alpha}{\beta+\alpha}}$ is also attained at $x_{2}$. By the AM-GM inequality, at $x_{2}$, we have $G \cdot\left(\frac{\omega_{0}^{n}}{\omega_{t}^{n}}\right)^{\frac{\alpha}{2 \beta+\alpha}} \leq G \cdot\left(\frac{G}{n}\right)^{\frac{\alpha n}{2 \beta+\alpha}}$. By $(3.17)$, we have $\sup _{X} G \cdot\left(\frac{\omega_{0}^{n}}{\omega_{t}^{n}}\right)^{\frac{\alpha}{2 \beta+\alpha}} \leq C^{\prime \prime \prime}$. Again by (3.16), we get

$$
\begin{equation*}
\omega_{t} \geq \widetilde{C} \omega_{0} \tag{3.19}
\end{equation*}
$$

where $\widetilde{C}$ is a positive number and independent of $t$. Combining (3.16) and (3.19), for some positive $C>0$ independent of $t$, we have

$$
\begin{equation*}
C^{-1} \omega_{0} \leq \omega_{t} \leq C \omega_{0} \tag{3.20}
\end{equation*}
$$

Therefore we obtain the higher order estimates (see [25]). Moreover, $\omega_{t}$ converges to a smooth Kähler form as $t \rightarrow T$. This is a contradiction since $T$ is the minimum existence time of $\varphi_{t}$. Therefore, there must holds $T \leq \frac{2 n \lambda}{(n+1) \alpha}$. This completes the proof of Lemma 3.1 (a).

If $\lambda<0$, by $((3.10))$, it is easy to get that

$$
\begin{equation*}
\Delta_{\omega_{t}}\left(\log G-\frac{\alpha}{2 \beta} \varphi_{t}\right) \geq\left(\frac{(n+1) \alpha t-(n+1) \lambda}{2 \beta n}\right) G-\left(\frac{\alpha n}{\beta}+1\right) \tag{3.21}
\end{equation*}
$$

Following the proof of Lemma 3.1 (a), we can easily prove Lemma 3.1 (b).
Proof of Theorem 1.2: The proof of Theorem 1.2 is similar to that of Theorem 1.1. For completeness, we give a detailed proof. We consider the following complex MongeAmpère equation for $\varphi_{t}$ :

$$
\begin{equation*}
\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}\right)^{n}=e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{0}^{n} \tag{3.22}
\end{equation*}
$$

let $\omega_{t}=t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}$. By Lemma 3.1, we have that

$$
\begin{equation*}
\Delta_{\omega_{t}}\left(\log \left(\operatorname{tr}_{\omega_{t}} \omega_{0}\right)-\frac{\alpha}{2 \beta} \varphi_{t}\right) \geq\left(\frac{(n+1) \alpha t-\tau_{\omega_{0}}}{2 \beta n}\right) \operatorname{tr}_{\omega_{t}}\left(\omega_{0}\right)-\left(\frac{\alpha n}{\beta}+1\right) \tag{3.23}
\end{equation*}
$$

and there exists smooth solution $\varphi_{t}$ for $t \in\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha},+\infty\right)$. In the following we just consider $t \in\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha}, \frac{4 n \lambda_{\omega_{0}}}{(n+1) \alpha}\right]$. Integrating (3.23) gives

$$
\begin{align*}
\left(\frac{\alpha n}{\beta}+1\right) \int_{X} \omega_{t}^{n} & \geq \int_{X}\left(\frac{(n+1) \alpha t}{2 \beta n}-\frac{\tau_{\omega_{0}}}{2 \beta n}\right)\left(\operatorname{tr}_{\omega_{t}} \omega_{0}\right) \omega_{t}^{n} \\
& \geq-\frac{1}{2 \beta n} \int_{u} \tau_{\omega_{0}}\left(\operatorname{tr}_{\omega_{t}} \omega_{0}\right) \omega_{t}^{n} \\
& \geq-\frac{1}{2 \beta} \int_{u} \tau_{\omega_{0}} \cdot\left(\frac{\omega_{0}^{n}}{\omega_{t}^{n}}\right)^{\frac{1}{n}} \omega_{t}^{n} \\
& =-\frac{1}{2 \beta} \int_{u} \tau_{\omega_{0}} \cdot e^{-\frac{1}{n}\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{t}^{n} \\
& \geq-\frac{1}{2 \beta} e^{-\frac{1}{n}\left(1+\frac{\alpha}{2 \beta}\right) \sup _{X} \varphi_{t}} \int_{u} \tau_{\omega_{0}} \omega_{t}^{n} \tag{3.24}
\end{align*}
$$

Now let us estimate the bounds of the following fractions:

$$
\begin{equation*}
\frac{-\int_{u} \tau_{\omega_{0}} \omega_{t}^{n}}{\int_{X} \omega_{t}^{n}}=\frac{-\int_{\mathcal{U}} \tau_{\omega_{0}} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{0}^{n}}{\int_{X} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{0}^{n}}=\frac{-\int_{u} \tau_{\omega_{0}} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}^{*}} \omega_{0}^{n}}{\int_{X} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}^{*}} \omega_{0}^{n}}, \tag{3.25}
\end{equation*}
$$

where $\varphi_{t}^{*}:=\varphi_{t}-\sup _{X} \varphi_{t}$. We fix a nonnegative number $b_{0} \geq 0$ such that $\operatorname{Ric}_{\omega_{0}} \geq$ $-b_{0} \omega_{0}$. Applying the maximum principle to $\varphi_{t}$, by (3.22), we get that

$$
\begin{align*}
\sup _{X} \varphi_{t} & \leq \frac{2 \beta}{\alpha+2 \beta} \log \left(\frac{4 n \varepsilon}{(n+1) \alpha}+b_{0}\right)^{n} \\
& \leq \frac{2 \beta}{\alpha+2 \beta} \log \left(c_{0}+b_{0}\right)^{n} \tag{3.26}
\end{align*}
$$

for $t \in\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha}, \frac{4 n \lambda_{\omega_{0}}}{(n+1) \alpha}\right]$, where $c_{0}$ is a positive number such that the $\alpha$-invariant $\alpha\left(X, c_{0} \omega_{0}\right) \geq 2$ and we choose $\varepsilon \leq \frac{(n+1) \alpha c_{0}}{4 n}$. Set

$$
c_{1}:=\inf \left\{\int_{u} e^{u} \omega_{0}^{n} \mid u \in \operatorname{PSH}\left(X,\left(c_{0}+b_{0}\right) \omega_{0}\right), \sup _{X} u=0\right\},
$$

which is a positive number depending only on $\mathcal{U}, \omega_{0}, c_{0}, b_{0}$, and hence only on $\mathcal{U}, \omega_{0}$. Then, for $t \in\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha}, \frac{4 n \lambda_{\omega_{0}}}{(n+1) \alpha}\right]$, we have

$$
-\int_{\mathcal{U}} \tau_{\omega_{0}} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}^{*}} \omega_{0}^{n} \geq(n+1) \delta \int_{\mathcal{U}} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}^{*}} \omega_{0}^{n} \geq(n+1) \delta c_{1}
$$

Since $\sup _{X} \varphi_{t}^{*}=0$, so we get

$$
\int_{X} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}^{*}} \omega_{0}^{n} \leq \int_{X} \omega_{0}^{n}=: \quad c_{2}
$$

where $c_{2}$ is a positive number depending only on $\omega_{0}$. In conclusion, we obtain that for $t \in\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha}, \frac{4 n \lambda_{\omega_{0}}}{(n+1) \alpha}\right]$,

$$
\frac{-\int_{u} \tau_{\omega_{0}} \omega_{t}^{n}}{\int_{X} \omega_{t}^{n}} \geq \frac{(n+1) \delta c_{1}}{c_{2}}
$$

with, combining with (3.24), concludes

$$
\sup _{u} \varphi_{t} \geq \frac{2 \beta n}{\alpha+2 \beta} \log \frac{(n+1) \delta c_{1}}{(2 \alpha n+2 \beta) c_{2}} .
$$

Now we define
$c_{3}:=\inf \left\{\int_{X} e^{v} \omega_{0}^{n} \mid v \in \operatorname{PSH}\left(X, c_{0} b_{0} \omega_{0}\right), n \log \frac{(n+1) \delta c_{1}}{(2 \alpha n+2 \beta) c_{2}} \leq \sup _{X} v \leq \log \left(c_{0}+b_{0}\right)^{n}\right\}$,
which is a positive number depending only on $U, \omega_{0}, \delta$. Therefore,

$$
\begin{align*}
\int_{X}\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha} \omega_{0}-\operatorname{Ric}_{\omega_{0}}\right)^{n} & =\lim _{t \rightarrow \frac{2 n \lambda \omega_{0}}{(n+1) \alpha}} \int_{X}\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}\right)^{n} \\
& =\lim _{t \rightarrow \frac{2 n \lambda \omega_{0}}{(n+1) \alpha}} \int_{X} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{0}^{n} \\
& \geq \liminf _{t \rightarrow \frac{2 n \lambda \omega_{0}}{(n+1) \alpha}} \int_{X} e^{\left(1+\frac{\alpha}{2 \beta}\right) \varphi_{t}} \omega_{0}^{n} \\
& \geq c_{3} \tag{3.27}
\end{align*}
$$

On the other hand,

$$
\begin{align*}
\int_{X}\left(\frac{2 n \lambda_{\omega_{0}}}{(n+1) \alpha} \omega_{0}-\operatorname{Ric}_{\omega_{0}}\right)^{n} & =\lim _{t \rightarrow \frac{2 n \lambda \omega_{0}}{(n+1) \alpha}} \int_{X}\left(t \omega_{0}-\operatorname{Ric}_{\omega_{0}}+d d^{c} \varphi_{t}\right)^{n} \\
& \leq \int_{X}\left(\frac{4 n \varepsilon}{(n+1) \alpha} \omega_{0}-\operatorname{Ric}_{\omega_{0}}\right)^{n} \\
& \leq \int_{X}\left(-\operatorname{Ric}_{\omega_{0}}\right)^{n}+c_{4} \varepsilon \\
& =\int_{X}\left(2 \pi c_{1}\left(K_{X}\right)\right)^{n}+c_{4} \varepsilon \tag{3.28}
\end{align*}
$$

where $c_{4}$ is positive number depending only on $\omega_{0}$. by (3.27) and (3.28), we have that

$$
\int_{X}\left(2 \pi c_{1}\left(K_{X}\right)\right)^{n} \geq c_{3}-c_{4} \varepsilon .
$$

Therefore, if $\varepsilon \leq \min \left\{\frac{c_{3}}{2 c_{4}}, \frac{\left.(n+1) \alpha c_{0}\right)}{4 n}\right\}$, we have $\int_{X}\left(2 \pi c_{1}\left(K_{X}\right)\right)^{n} \geq \frac{c_{3}}{2}>0$.
Proof of Theorem 1.3. We note that the argument can be repeated more or less without change to prove Theorem 1.3. The only modification is that one requires [18, Lemma 2.1].
