Vocabulary for Universal Approximation: A Linguistic Perspective of Mapping Compositions

Yongqiang Cai School of Mathematical Sciences, Beijing Normal University caiyq.math@bnu.edu.cn

Abstract

In recent years, deep learning-based sequence modelings, such as language models, have received much attention and success, which pushes researchers to explore the possibility of transforming non-sequential problems into a sequential form. Following this thought, deep neural networks can be represented as composite functions of a sequence of mappings, linear or nonlinear, where each composition can be viewed as a *word*. However, the weights of linear mappings are undetermined and hence require an infinite number of words. In this article, we investigate the finite case and constructively prove the existence of a finite *vocabulary* $V = \{\phi_i : \mathbb{R}^d \to \mathbb{R}^d | i = 1, ..., n\}$ with $n = O(d^2)$ for the universal approximation. That is, for any continuous mapping $f : \mathbb{R}^d \to \mathbb{R}^d$, compact domain Ω and $\varepsilon > 0$, there is a sequence of mappings $\phi_{i_1}, ..., \phi_{i_m} \in V, m \in \mathbb{Z}_+$, such that the composition $\phi_{i_m} \circ ... \circ \phi_{i_1}$ approximates f on Ω with an error less than ε . Our results provide a linguistic perspective of composite mappings and suggest a cross-disciplinary study between linguistics and approximation theory.

1 Introduction

Cognitive psychologists and linguisticians have long recognized the importance of languages [30], which has been further highlighted by the popularity of language models such as BERT [14] and GPT [6]. These models, based on RNNs or Transformers, have revolutionized natural language processing by transforming it into a sequence learning problem. They can handle the long-term dependencies in text and generate coherent text based on the previous content, making them invaluable tools in language understanding and generation [34]. The success of these models has also led to a new approach to solving non-sequential problems by transforming them into sequential ones. For instance, image processing can be turned into a sequence learning problem by segmenting an image into small blocks, arranging them in a certain order, and then processing the resulting sequence using sequence learning algorithms to achieve image recognition [15]. The use of sequence learning algorithms has also been extended to reinforcement learning [9], such as the decision transformer outputs the optimal actions by leveraging a causally masked transformer and exceeds the state-of-the-art performance.

Sequence modeling has opened up new possibilities for solving a wide range of problems, and this trend seems to hold in the field of theoretical research. As is well known, artificial neural networks have universal approximation capabilities, and wide or deep feedforward networks can approximate continuous functions on a compact domain arbitrarily well [13; 22; 26]. However, in practical applications such as AlphaFold [24], BERT [14] and GPT [6], the residual network structures [19; 20] are more preferred than the feedforward structures. It is observed that residual networks (ResNets) are forward Euler discretizations of dynamical systems [17; 31], and this relationship has spawned a series of dynamical system-based neural network structures such as the neural ODE [10]. The dynamical system-based neural network structures are expected to play an important role in various fields.

Notably, both the language models and the dynamical systems are linked to time series modeling and have been effectively applied to non-sequential problems. This observation naturally leads us to question: is there an intricate relationship between their individual successes? This article aims to ponder upon the question. Through a comparative study, we obtain some initial results from the perspective of universal approximation. Specifically, we demonstrate that there exist a finite set of mappings, referred to as the vocabulary V, choosing as flow maps of some autonomous dynamical system x'(t) = f(x(t)), such that any continuous mapping can be approximated by compositing a sequence of mappings in the vocabulary V. This bears a resemblance to the way complex information is conveyed in natural language through constructing phrases, sentences, and ultimately paragraphs and compositions. Table 1 provides an intuitive representation of this similarity.

English		Flow map of dynamical systems \ddagger	
Vocabulary	${\sim}140{,}000^\dagger$	$O(d^2)$	
Word	I, you, am, is, are, apple, banana, car, buy, do, have, blue, red,		
Phrase	A big deal, easier said than done, time waits for no man,	$\phi_{e_1}^{\tau} \bullet \phi_{-e_2}^{\tau}, \phi_{e_1}^{\tau} \bullet \phi_{E_{11}x}^{\tau} \bullet \phi_{\operatorname{ReLU}(x)}^{\tau}, \dots$	
Sentence	It was the best of times, it was the worst of times, it was the age of wisdom, it was the age of foolishness,		

Table 1: Comparison of natural languages and dynamical systems in dimension d

[†] The number of words, phrases, and meanings in Cambridge Advanced Learner's Dictionary. [‡] Notations are provided in Section 2.

1.1 Contributions

- 1. We proved that it is possible to achieve the universal approximation property by compositing a sequence of mappings in a finite set V. (Theorem 2.2 and Corollary 2.3).
- 2. Our proof is constructive as we designed such a V that contains finite number of flow maps of dynamical systems. (Theorem 2.6)
- 3. We built an analogy between composite flow maps and words/phrases/sentences in natural languages (Table 1), which could inspire cross-disciplinary studies between approximation theory, dynamical systems, sequence modeling, and linguistics.

1.2 Related works

Universal approximation. The approximation properties of neural networks have been extensively studied, with previous studies focusing on the approximation properties of network structures such as feedforward neural networks [13; 22; 26] and residual networks [19; 20]. In these networks, the structure is fixed and the weights are adjusted to approximate target functions. Although this paper also considers universal approximation properties, we use a completely different way. We use a finite set of mappings, and the universal approximation is achieved by composing sequences of these mappings. The length of the mapping sequence is variable, which is similar to networks with a fixed width and variable depth [28; 23; 25; 29; 4; 7]. However, in our study, we do not consider learnable weights; instead, we consider the composition sequence, which is different from previous research.

Residual network, neural ODE, and control theory. The word mapping constructed in this paper is partially based on the numerical discretization of dynamical systems and therefore has a relationship with residual networks and neural ODEs. Residual networks [19; 20] are currently one of the most popular network structures and can be viewed as a forward Euler discretization of neural ODEs [10]. Recently, Li et al. [27] and Tabuada et al. [32; 33] studied the approximation properties of neural ODEs. Their basic idea is employing controllability results in control theory to construct source terms that approximate a given finite number of input-output pairs, thus obtaining the approximation properties of functions in the L^p norm or continuous norm sense. Additionally, Duan et

al. [16] proposed an operator splitting format that discretizes neural ODEs into Leaky-ReLU fully connected networks. Partially inspired by Duan et al.'s construction, we designed a special splitting method to finish Part 1 of our construction.

It's worth noting that all neural networks mentioned above can be represented as compositions of mapping sequences. Since the weights involved in the networks are undetermined, an infinite number of mappings are required. However, our construction only requires a finite number of mappings, which is closer to the fact that finite words are used to express infinite ideas in natural language, and is helpful in inspiring interdisciplinary research.

1.3 Outline

We state the main result for universal approximation in Section 2, which includes notations, main theorems, and ideas for construction and proof. Before providing the detailed construction in Section 4, we add a Section 3 to introduce flow maps and the techniques we used. Finally, in Section 5 we discuss the result of this paper. All formal proof of the theorems are provided in the Appendix.

2 Notations and main results

For a (vector valued) function class \mathcal{F} , the *vocabulary* V is defined as a finite subset of \mathcal{F} , *i.e.*,

$$V \equiv V_{\mathcal{F}} = \{ \phi_i \in \mathcal{F} | i = 1, 2, ..., n \}, \quad n \in \mathbb{Z}_+.$$
(1)

Each $\phi_i \in V$ is called a *word*. We will consider a sequence of functions, $\phi_{i_1}, \phi_{i_2}, ..., \phi_{i_m} \in V$, and their composition, called as a *sentence*, to generate the hypothesis function space,

$$\mathcal{H}_V = \{\phi_{i_1} \bullet \phi_{i_2} \bullet \dots \bullet \phi_{i_m} | \phi_{i_1}, \phi_{i_2}, \dots, \phi_{i_m} \in V, m \in \mathbb{Z}_+\}.$$
(2)

Particularly, some (short) sentences are called *phrases* for some purpose. Here the operator \bullet is defined as function composition from left to right, which aligns the composition order to the writing order, *i.e.*

$$\phi_{i_1} \bullet \phi_{i_2} \bullet \dots \bullet \phi_{i_m} = \phi_{i_m} \circ \dots \circ \phi_{i_2} \circ \phi_{i_1} = \phi_{i_m} (\dots (\phi_{i_2}(\phi_{i_1}(\cdot))) \dots).$$
(3)

In additional, we use $\phi^{\bullet m}$, to denote the mapping that composites ϕm times.

In this paper, we consider two function classes: (1) $C(\mathbb{R}^d, \mathbb{R}^d)$, continuous functions from \mathbb{R}^d to \mathbb{R}^d , (2) Diff₀(\mathbb{R}^d), orientation-preserving (OP) diffeomorphisms of \mathbb{R}^d . Particularly, we will restrict the functions on a compact domain $\Omega \subset \mathbb{R}^d$ and define the universal approximation property as below.

Definition 2.1 (Universal approximation property, UAP). For the compact domain Ω in dimension *d*, the target function space \mathcal{F} and the hypothesis space \mathcal{H} , we say

- 1. *H* has C-UAP for *F*, if for any $f \in F$ and $\varepsilon > 0$, there is a function $h \in H$ such that $\|f(x) - h(x)\| < \varepsilon, \quad \forall x \in \Omega.$
- 2. *H* has L^p -UAP for \mathcal{F} , if for any $f \in \mathcal{F}$ and $\varepsilon > 0$, there is a function $h \in \mathcal{H}$ such that

$$||f - h||_{L^p(\Omega)} < \varepsilon, \quad p \in [1, +\infty).$$

2.1 Main theorem

Our main result is Theorem 2.2 and its Corollary 2.3 which show the existence of a finite function vocabulary V for the universal approximation property.

Theorem 2.2. Let $\Omega \subset \mathbb{R}^d$ be a compact domain. Then, there is a finite set $V \subset Diff_0(\mathbb{R}^d)$ such that the hypothesis space \mathcal{H}_V in Eq. (2) has C-UAP for $Diff_0(\mathbb{R}^d)$.

Corollary 2.3. Let $\Omega \subset \mathbb{R}^d$ be a compact domain, $d \geq 2$ and $p \in [1, +\infty)$. Then, there is a finite set $V \subset C(\mathbb{R}^d, \mathbb{R}^d)$ such that the hypothesis space \mathcal{H}_V in Eq. (2) has L^p -UAP for $C(\mathbb{R}^d, \mathbb{R}^d)$.

The Corollary 2.3 is based on the fact that OP diffeomorphisms can approximate continuous functions under the L^p norm provided the dimension is larger than two [5]. Next, we only need to prove Theorem 2.2. **Remark 2.4.** We are considering functions to have the same dimension of the input and output, for simplicity. Our results can be directly extended to the case of different input and output dimensions. In fact, for $f \in C(\mathbb{R}^{d_x}, \mathbb{R}^{d_y})$, one can lift it as a function $\tilde{f} \in C(\mathbb{R}^d, \mathbb{R}^d)$ with some $d \geq \max(d_x, d_y)$. For example, let $f = A_{in} \bullet \tilde{f} \bullet A_{out}$ where $A_{in} \in C(\mathbb{R}^{d_x}, \mathbb{R}^d)$ and $A_{out} \in C(\mathbb{R}^d, \mathbb{R}^{d_y})$ are two fixed affine mappings.

2.2 Sketch of the proof

Our proof for Theorem 2.2 is constructive, by concerening the flow maps of ODEs. Consider the following ODE dynamical system in dimension d,

$$\begin{cases} \dot{x}(t) = v(x(t), t), t \in (0, \tau), \\ x(0) = x_0 \in \mathbb{R}^d, \end{cases}$$
(4)

where $v : \mathbb{R}^d \to \mathbb{R}^d$ is the velocity field. The flow map from x_0 to $x(\tau)$ is denoted by $\phi_{v(x,t)}^{\tau}(x_0)$ which is naturally an OP diffeomorphism. An introduction to flows and dynamical systems can be found in [3].

Our construction will use the following class of candidate flow maps,

$$H_1 = \left\{ \phi_{Ax+b}^{\tau} \mid A \in \mathbb{R}^{d \times d}, b \in \mathbb{R}^d, \tau \ge 0 \right\} \equiv \left\{ \phi : x \to e^A x + \tilde{b} \mid \tilde{A} \in \mathbb{R}^{d \times d}, \tilde{b} \in \mathbb{R}^d \right\},$$
(5)

$$H_2 = \left\{ \phi_{\Sigma_{\boldsymbol{\alpha},\boldsymbol{\beta}}(x)}^{\tau} \mid \boldsymbol{\alpha}, \boldsymbol{\beta} \in \mathbb{R}^d, \tau \ge 0 \right\} \equiv \left\{ \phi : x \to \Sigma_{\tilde{\boldsymbol{\alpha}}, \tilde{\boldsymbol{\beta}}}(x) \mid \tilde{\boldsymbol{\alpha}}, \tilde{\boldsymbol{\beta}} \in (0, +\infty)^d \right\},\tag{6}$$

where $\Sigma_{\alpha,\beta}$ is the generalized leaky-ReLU functions defined as below. We say H_1 the affine flows and H_2 the leaky-ReLU flows.

Definition 2.5 (Generalized leaky-ReLU). *Define the generalized leaky-ReLU function as* $\sigma_{\alpha,\beta}$: $\mathbb{R} \to \mathbb{R}$ and $\Sigma_{\alpha,\beta} : \mathbb{R}^d \to \mathbb{R}^d$, with $\alpha, \beta \in \mathbb{R}$, $\alpha = (\alpha_1, ..., \alpha_d) \in \mathbb{R}^d$, $\beta = (\beta_1, ..., \beta_d) \in \mathbb{R}^d$,

$$\sigma_{\alpha,\beta}(x) = \begin{cases} \alpha x, & x < 0\\ \beta x, & x \ge 0 \end{cases}, \quad \Sigma_{\alpha,\beta}(x) = \left(\sigma_{\alpha_1,\beta_1}(x_1), ..., \sigma_{\alpha_d,\beta_d}(x_d)\right). \tag{7}$$

Generalized leaky-ReLU functions are piecewise linear functions. Using this notation, the traditional ReLU and leaky-ReLU functions are ReLU(x) $\equiv \sigma_0(x) \equiv \sigma_{0,1}(x)$ and $\sigma_{\alpha}(x) \equiv \sigma_{\alpha,1}(x)$ with $\alpha \in (0, 1)$, respectively. For vector input x, we use $\sigma_{\alpha,\beta}$ as an equivilant notation of $\Sigma_{\alpha 1,\beta 1}$.

We will show that the following set V meets our requirement for universal approximations,

$$V = \left\{ \phi_{\pm e_i}^{\tau}, \phi_{\pm E_{ij}x}^{\tau}, \phi_{\pm \Sigma_{e_i,0}(x)}^{\tau}, \phi_{\pm \Sigma_{0,e_i}(x)}^{\tau} \mid i, j \in \{1, 2, ..., d\}, \tau \in \{1, \sqrt{2}\} \right\},\tag{8}$$

where $e_i \in \mathbb{R}^d$ is the *i*-th unit coordinate vector, E_{ij} is the $d \times d$ matrix that has zeros in all entries except for a 1 at the index (i, j). Obviously, $V \subset \text{Diff}_0(\mathbb{R}^d)$ is a finite set with $O(d^2)$ functions.

Theorem 2.6. Let $\Psi \in Diff_0(\Omega)$ be an orientation preserving diffeomorphism, Ω be a compact domain $\Omega \subset \mathbb{R}^d$. Then, for any $\varepsilon > 0$, there is a sequence of flow maps, $\phi_1, \phi_2, ..., \phi_n \in V, n \in \mathbb{Z}_+$, such that

$$\|\Psi(x) - (\phi_1 \bullet \phi_2 \bullet \dots \bullet \phi_n)(x)\| \le \varepsilon, \quad \forall x \in \Omega.$$
(9)

Theorem 2.6 provides a constructive proof for Theorem 2.3. The proof of Theorem 2.6 can be separated into the following two parts.

Part 1: Approximate $\Psi \in \text{Diff}_0(\mathbb{R}^d)$ by compositing a sequence of flow maps in $H_1 \cup H_2$. Particularly, we approximate Ψ by g_L is of the form

$$g_L = P_0 \bullet \Sigma_1 \bullet P_1 \bullet \Sigma_2 \bullet \dots \bullet \Sigma_L \bullet P_L, \quad P_i \in H_1, \Sigma_i \in H_2, L \in \mathbb{Z}_+.$$
(10)

Part 2: Approximate each flow map in H_1 and H_2 by compositing a sequence of flow maps in V.

The validation of such constructed V is technical and will be proved in Section 3 and Section 4. Here we only explain the main ideas. First of all, we note that to approximate a composition map T, we only need to approximate each component in T, which is detailed in the following Lemma 2.7.

Lemma 2.7. Let map $T = F_1 \bullet ... \bullet F_n$ be a composition of n continuous functions F_i defined on an open domain D_i , and let \mathcal{F} be a continuous function class that can uniformly approximate each F_i on any compact domain $\mathcal{K}_i \subset D_i$. Then, for any compact domain $\mathcal{K} \subset D_1$ and $\varepsilon > 0$, there are n functions $\tilde{F}_1, ..., \tilde{F}_n$ in \mathcal{F} such that

$$\|T(x) - \tilde{F}_1 \bullet \dots \bullet \tilde{F}_n(x)\| \le \varepsilon, \quad \forall x \in \mathcal{K}.$$
(11)

Then for Part 1, we note that the g_L we constructed in Eq. (10) is similar to a feedforward neural network g_L with width d and depth L. In fact, the form of g_L is motivated by a recent work of Duan et.al [16] which proved that vanilla feedforward leaky-ReLU networks with width d can be a discretization of dynamic systems in dimension d. However, affine transformations in general networks are not necessary to be OP diffeomorphisms, and one novelty of this paper is improving the technique to construct P_i as flow maps. Importantly, making them flow maps helps with Part 2 of our construction.

For Part 2, the validation involves three techniques in math: the Lie product formula [18], the splitting method [21] and the Kronecker's theorem [2]. We take $\phi_b^1, b = \sum_{i=1}^d \pm \beta_i e_i, \beta_i \ge 0$, as an example to illustrate the main idea. Firstly, motivated by the Lie product formula or the splitting method, we can approximate ϕ_b^1 by

$$\phi_b^1 \approx \left(\phi_{\pm e_1}^{\beta_1/n} \bullet \phi_{\pm e_2}^{\beta_2/n} \bullet \dots \bullet \phi_{\pm e_d}^{\beta_d/n}\right)^{\bullet n}, \quad n \in \mathbb{Z}_+,$$
(12)

with *n* large enough. Secondly, each $\phi_{\pm e_i}^{\beta_i/n}$ can be approximated by

$$\phi_{\pm e_i}^{\beta_i/n} \approx (\phi_{\pm e_i}^1)^{\bullet p_i} \bullet (\phi_{\mp e_i}^{\sqrt{2}})^{\bullet q_i} \in \mathcal{H}_V, \quad p_i, q_i \in \mathbb{Z}_+$$
(13)

where p_i and q_i are non-negative integers such that $|p_i - q_i\sqrt{2} - \beta_i/n|$ is small enough according to the Kronecker's theorem [2] as $\sqrt{2}$ is an irrational number. Finally, ϕ_b^1 can be approximated by compositing a sequence of flow maps in V. The case for ϕ_{Ax+b}^{τ} and $\phi_{\Sigma_{\alpha,\beta}(x)}^{\tau}$ in H_1 and H_2 can be done in the same spirit.

3 Warm up

To warm up, we show some flow maps of autonomous ODEs below,

$$\dot{x}(t) = b, \quad x(0) = x_0 \qquad \Rightarrow \qquad x(t) = \phi_b^t(x_0) = x_0 + bt,$$
(14)

$$\dot{x}(t) = Ax(t) + b, \quad x(0) = x_0 \qquad \Rightarrow \qquad x(t) = e^{At}x_0 + \int_0^t e^{A(t-\tau)}bd\tau,$$
 (15)

$$\dot{x}(t) = a\sigma_0(x(t)), \quad x(0) = x_0 \qquad \Rightarrow \qquad x(t) = \phi_{a\sigma_0(x)}^t(x_0) = e^{at}\sigma_{e^{-at}}(x_0),$$
(16)

$$\dot{x}(t) = a\sigma_0(-x(t)), \quad x(0) = x_0 \qquad \Rightarrow \qquad x(t) = \phi^t_{a\sigma_0(-x)}(x_0) = \sigma_{e^{-at}}(x_0).$$
 (17)

Here σ_0 and $\sigma_{e^{-at}}$ are ReLU and leaky-ReLU functions, respectively. Next, we provide some properties to verify a given map to be an affine flow map in H_1 or a leaky-ReLU flow map in H_2 .

3.1 Affine flows and leaky-ReLU flows

Consider the affine transformation $P: x \to Wx + b$ and examine conditions of P to be a flow map. Generally, if W is nonsingular and has real matrix logarithm $\ln(W)$, then P is an affine flow map, as we can represent P as $P(x) = Wx + b = \phi_{Ax+\tilde{b}}^1$ where $A = \ln(W)$ and $\tilde{b} = \int_0^1 e^{A(\tau-1)} b d\tau$. As it is hard to verify $\ln(W)$ a real matrix [11], we are happy to construct some special matrix W. The following properties are useful.

Proposition 3.1. (1) Let Q be a nonsingular matrix. If $x \to Wx$ is an affine flow map then the map $x \to QWQ^{-1}x$, $x \to W^Tx$ and $x \to W^{-1}x$ also are. (2) Let U be an upper triangular matrix below with $\lambda > 0$, then the map $x \to Ux$ is an affine flow map for arbitrary vector $w_{2:d}$,

$$U = \begin{pmatrix} \lambda & w_{2:d} \\ 0 & I_{d-1} \end{pmatrix}.$$
 (18)

Here I_{d-1} is the (d-1)th order identity matrix. The property (1) is because $\ln(QWQ^{-1}) = Q \ln(W)Q^{-1}$ and $\ln(W^T) = \ln(W)^T$. The property (2) can be obtained by employing the formula,

$$\ln \begin{pmatrix} \lambda & w_{2:d} \\ 0 & I_{d-1} \end{pmatrix} = \begin{pmatrix} \ln(\lambda) & \frac{\ln(\lambda)}{\lambda - 1} w_{2:d} \\ 0 & 0 \end{pmatrix}, \quad \lambda \neq 1.$$
(19)

When $\lambda = 1$, the formula is simplified as $\ln(U) = U - I_d$.

Next, we consider the leaky-ReLU flow maps.

By directly calculate the flow map $\phi_{\Sigma_{\alpha,\beta}(x)}^{\tau}$ with $\alpha, \beta \in \mathbb{R}^d$, we have

$$\phi_{\Sigma_{\alpha,\beta}(x)}^{\tau}(x) = \Sigma_{\tilde{\alpha},\tilde{\beta}}(x), \tag{20}$$

where $\tilde{\boldsymbol{\alpha}} = (e^{\tau \alpha_1}, ..., e^{\tau \alpha_d})$ and $\tilde{\boldsymbol{\beta}} = (e^{\tau \beta_1}, ..., e^{\tau \beta_d})$. The following property is implied. **Proposition 3.2.** If $\tilde{\boldsymbol{\alpha}}, \tilde{\boldsymbol{\beta}} \in (0, \infty)^d$, then the map $\sum_{\tilde{\boldsymbol{\alpha}}, \tilde{\boldsymbol{\beta}}}$ is a leaky-ReLU flow map.

3.2 Application of Lie product formula

Theorem 3.3 (Lie product formula). For all matrix $A, B \in \mathbb{R}^{d \times d}$, we have

$$e^{A+B} = \lim_{n \to \infty} \left(e^{A/n} e^{B/n} \right)^n = \lim_{n \to \infty} \left(\phi_{Ax}^{1/n} \bullet \phi_{Bx}^{1/n} \right)^{\bullet n} \tag{21}$$

Here e^A denotes the matrix exponential of A, which is also the flow map ϕ_{Ax}^1 of the autonomous system x'(t) = Ax(t). The proof can be found in [18] for example and the formula can be extended to multi-component cases. The formula can also be derived from the operator splitting approach [21], which allows us to obtain the following result.

Lemma 3.4. Let $v_i : \mathbb{R}^d \to \mathbb{R}^d$, i = 1, 2, ..., m be Lipschitz continuous funcitons, $v = \sum_{i=1}^m v_i$, Ω be a compact domain. For any t > 0 and $\varepsilon > 0$, there is a positive integers n, such that the flow map ϕ_v^t can be approximated by composition of flow maps $\phi_{v_i}^{t/n}$, i.e.

$$\|\phi_v^t(x) - \left(\phi_{v_1}^{t/n} \bullet \phi_{v_2}^{t/n} \bullet \dots \bullet \phi_{v_m}^{t/n}\right)^{\bullet n}(x)\| < \varepsilon, \quad \forall x \in \Omega.$$
(22)

3.3 Application of Kronecker's theorem

Theorem 3.5 (Kronecker's approximation theorem [2]). Let $\gamma \in \mathbb{R}$ be an irrational number, then for any $t \in \mathbb{R}$ and $\varepsilon > 0$, there exist two integers p and q with q > 0, such that $|\gamma q + p - t| < \varepsilon$.

Although Kronecker's Theorem 3.5 is proposed for approximating real numbers, we can employ it in the scenario of approximating the flow map ϕ_v^t as it contains a real-time parameter t. Choosing $\gamma = -\sqrt{2}$, approximating t by $p - q\sqrt{2}$, then we can approximate ϕ_v^t by $\phi_v^{p-q\sqrt{2}}$. Considering positive t, we have p is positive as q is. Then the property of flow maps,

$$\phi_v^{p-q\sqrt{2}} = \phi_v^p \bullet \phi_v^{-q\sqrt{2}} = \phi_v^p \bullet \phi_{-v}^{q\sqrt{2}} = (\phi_v^1)^{\bullet p} \bullet (\phi_{-v}^{\sqrt{2}})^{\bullet q},$$
(23)

allow us to prove the following result.

Lemma 3.6. Let $v : \mathbb{R}^d \to \mathbb{R}^d$ be a Lipschitz continuous function, Ω be a compact domain. For any t > 0 and $\varepsilon > 0$, there exist two positive integers p and q, such that the flow map ϕ_v^t can be approximated by $(\phi_v^1)^{\bullet p} \bullet (\phi_{-v}^{\sqrt{2}})^{\bullet q}$, i.e.

$$\|\phi_v^t(x) - (\phi_v^1)^{\bullet p} \bullet (\phi_{-v}^{\sqrt{2}})^{\bullet q}(x)\| < \varepsilon, \quad \forall x \in \Omega.$$
(24)

Corollary 3.7. For any flow maps h in $H_1 \cup H_2$, $\varepsilon > 0$ and compact domain $\Omega \subset \mathbb{R}^d$, there is a sequence $\phi_1, \phi_2, ..., \phi_m$ in V (Eq. 8) such that

$$\|h(x) - (\phi_1 \bullet \phi_2 \dots \bullet \phi_m)(x)\| < \varepsilon, \quad \forall x \in \Omega.$$
(25)

The result is obtained by directly employing Lemma 3.4 and Lemma 3.6 with the following splittings,

$$Ax + b = \sum_{i=1}^{d} \sum_{j=1}^{d} a_{ij} E_{ij} x + \sum_{i=1}^{d} b_i e_i, \quad \Sigma_{\alpha,\beta}(x) = \sum_{i=1}^{d} \alpha_i \Sigma_{e_i,0}(x) + \sum_{i=1}^{d} \beta_i \Sigma_{0,e_i}(x).$$
(26)

4 Detailed construction for Theorem **2.6**

This section provides the construction that OP diffeomorphisms can be approximated by compositing a sequence of flow maps in V. The construction contains three steps: (1) approximate OP diffeomorphisms by deep compositions using the splitting approach, (2) approximate each splitting component by compositing flow maps in $H_1 \cup H_2$, (3) combine results to finish the construction.

4.1 Approximate the OP diffeomorphism by deep compositions

Employed results of [1; 8], any OP diffeomorphism Ψ can be approximated by flow maps of ODEs. Particularly, we can choose the ODEs as neural ODEs are of the form

$$x'(t) = v(x(t), t) = \sum_{i=1}^{N} s_i(t)\sigma(w_i(t) \cdot x(t) + b_i(t)),$$
(27)

where the field function v is a neural network with N hidden neurons, the activation is chosen as the leaky-ReLU function $\sigma = \sigma_{\alpha}$ for some $\alpha \in (0, 1)$, $s_i \in \mathbb{R}^d$, $w_i \in \mathbb{R}^d$ and $b_i \in \mathbb{R}$ are piecewise smooth functions of t. The universal approximation property of neural networks [12] implies that Ψ can be approximated by the flow map ϕ_v^{τ} of Eq. (57) for some $\tau > 0$ and $N \in \mathbb{Z}_+$ big enough.

Following the approach of [16], we employ a proper splitting numerical scheme to discretize the neural ODE (57). Split the field v as a summation of Nd functions, $v(x,t) = \sum_{i=1}^{N} \sum_{j=1}^{d} v_{ij}(x,t)e_j$, where e_j is the *j*-th axis unit vector and $v_{ij}(x,t) = s_{ij}(t)\sigma(w_i(t) \cdot x + b_i(t))$ are scalar functions. Then the numerical analysis theory of splitting methods [21] ensures that the following composition Φ can approximate ϕ^{τ} provided the time step $\Delta t := \tau/n$ is sufficiently small,

$$\Phi = T_1 \bullet \dots \bullet T_n \equiv (T_1^{(1,1)} \bullet T_1^{(1,2)} \bullet \dots \bullet T_1^{(N,d)}) \bullet \dots \bullet (T_n^{(1,1)} \bullet T_n^{(1,2)} \bullet \dots \bullet T_n^{(N,d)}),$$

where the map $T_k^{(i,j)}: x \to y$ in each split step is

$$\begin{cases} y^{(l)} = x^{(l)}, l \neq j, \\ y^{(j)} = x^{(j)} + \Delta t v_{ij}(x, k\Delta t). \end{cases}$$
(28)

Here, the superscript in $x^{(l)}$ indicates the *l*-th coordinate of x. The map $T_k^{i,j}$ is given by the forward Euler discretization of $x'(t) = v_{i,j}(x(t), t)e_j$ in the interval $(k\Delta t, (k+1)\Delta t)$. Note that v_{ij} is Lipschitz continuous on \mathbb{R}^d , hence the map $T_k^{i,j}$ also is.

Below is the formal statement of the approximation in this step.

Theorem 4.1. Let $\Psi \in Diff_0(\Omega)$ be an orientation preserving diffeomorphism, Ω be a compact domain $\Omega \subset \mathbb{R}^d$. Then, for any $\varepsilon > 0$, there is a sequence of transformations, $T_k^{(i,j)}$, is of the form Eq. (28) such that

$$\|\Psi(x) - (T_1^{(1,1)} \bullet T_1^{(1,2)} \bullet \dots \bullet T_1^{(N,d)} \bullet \dots \bullet T_n^{(1,1)} \bullet T_n^{(1,2)} \bullet \dots \bullet T_n^{(N,d)})(x)\| \le \varepsilon, \quad \forall x \in \Omega.$$

4.2 Approximate each composition component by flow maps in H_1 and H_2

Now we examine the map $T_k^{(i,j)}$ in each splitting step. Since all $T_k^{(i,j)}$ have the same structure (over a permutation), so we only need to consider the case of $T_k^{(N,d)}$, which is simply denoted as $T: x \to y$ is of the form

$$T: \begin{cases} y^{(i)} = x^{(i)}, i = 1, \cdots, d-1, \\ y^{(d)} = x^{(d)} + a\sigma(w_1 x^{(1)} + \cdots + w_d x^{(d)} + b). \end{cases}$$
(29)

where $\sigma = \sigma_{\alpha}, \alpha \in (0, 1)$, is the leaky-ReLU funciton, $a, b, w_1, ..., w_d \in \mathbb{R}$ are parameters. Since the time step Δt in $T_k^{(i,j)}$ are small, we can assume the parameters satisfing $\max(1/\alpha, \alpha)|aw_d| < 1$. Lemma 4.2. Let $\alpha > 0$ and $\max(1/\alpha, \alpha)|aw_d| < 1$, then the map T in Eq. (29) is a composition of at most six flow maps in $H_1 \cup H_2$. Noting that the case of $w_1 = ... = w_{d-1} = 0$ is trivial, we can assume $w_1 \neq 0$ without loss of generality. Then, the bias parameter b can be absorbed in $x^{(1)}$ using an affine flow map; hence we only need to consider the case of b = 0. In addition, using the property of leaky-ReLU, $\sigma_{\alpha}(x) = -\alpha \sigma_{1/\alpha}(-x)$, we can further assume $w_1 > 0$. As a result, the map T can be represented by the following composition,

$$T(x) = F_0 \bullet F_1 \bullet \dots \bullet F_5(x), \tag{30}$$

where each composition step is as follows,

$$\begin{pmatrix} x^{(1)} \\ x^{(2:d-1)} \\ x^{(d)} \end{pmatrix} \xrightarrow{F_0} \begin{pmatrix} \nu \\ x^{(2:d-1)} \\ x^{(d)} \end{pmatrix} \xrightarrow{F_1} \begin{pmatrix} \sigma(\nu) \\ x^{(2:d-1)} \\ x^{(d)} \end{pmatrix} \xrightarrow{F_2} \begin{pmatrix} \sigma(\nu) \\ x^{(2:d-1)} \\ x^{(d)} + a\sigma(\nu) \end{pmatrix} \xrightarrow{F_3} \begin{pmatrix} \nu \\ x^{(2:d-1)} \\ x^{(d)} + a\sigma(\nu) \end{pmatrix} \xrightarrow{F_4} \begin{pmatrix} \nu + w_d a \sigma(\nu) \\ x^{(2:d-1)} \\ x^{(d)} + a\sigma(\nu) \end{pmatrix} \xrightarrow{F_5} \begin{pmatrix} x^{(1)} \\ x^{(2:d-1)} \\ x^{(d)} + a\sigma(\nu) \end{pmatrix}.$$

Here, $\nu := w_1 x^{(1)} + \dots + w_d x^{(d)}$ and $x^{(2:d-1)}$ represent the elements $x^{(2)}, ..., x^{(d-1)}$.

We clarify that each component F_i , $i = 0, \dots, 5$, are flow maps in $H_1 \cup H_2$. In fact, $F_0, F_2, F_5 = F_0^{-1}$ are affine mappings,

$$F_0(x) = \begin{pmatrix} w_1 & w_{2:d} \\ 0 & I_{d-1} \end{pmatrix} x, \quad F_2(x) = \begin{pmatrix} I_{d-1} & 0 \\ (a, 0_{2:d-1}) & 1 \end{pmatrix} x, \quad F_5(x) = \begin{pmatrix} 1/w_1 & -w_{2:d}/w_1 \\ 0 & I_{d-1} \end{pmatrix} x,$$

where I_{d-1} is the identity matrix, $(a, 0_{2:d-1}) = (a, 0, ..., 0)$ with d-2 zeros. According to Proposition 3.1, they are flow maps in H_1 . In addition, according to Proposition 3.2, F_1 , F_3 and F_4 are leaky-ReLU flow maps in H_2 as

$$F_1 = \sum_{(\alpha, 1_{2:d}), 1_{1:d}}, \quad F_3 = \sum_{(1/\alpha, 1_{2:d}), 1_{1:d}}, \quad F_4 = \sum_{(1+w_d a \alpha, 1_{2:d}), (1+w_d a, 1_{2:d})}.$$
(31)

Here, the condition $\max(1/\alpha, \alpha)|aw_d| < 1$ is used to ensure $1 + w_d a \alpha > 0$ and $1 + w_d a > 0$.

4.3 Finish the construction

Combining Theorem 4.1 and Lemma 4.2 above, and using the fact in Lemma 2.7, we have the following result.

Theorem 4.3. Let $\Psi \in Diff_0(\Omega)$ be an orientation preserving diffeomorphism, Ω be a compact domain $\Omega \subset \mathbb{R}^d$. Then, for any $\varepsilon > 0$, there is a sequence of flow maps, $h_1, h_2, ..., h_m, m \in \mathbb{Z}_+$, in $H = H_1 \cup H_2$ such that

$$\|\Psi(x) - (h_1 \bullet h_2 \bullet \dots \bullet h_m)(x)\| \le \varepsilon, \quad \forall x \in \Omega.$$
(32)

Then we can finish the construction for Theorem 2.6 by combining Corollary 3.6 and Theorem 4.3.

5 Conclusion

Universal approximation properties are the foundation for machine learning. This paper examined the approximation property of mapping composition from a sequential perspective. We proved, for the first time, that the universal approximation for diffeomorphisms and high-dimensional continuous functions can be achieved by using a finite number of sequential mappings. Importantly, the mappings used in our composition are flow maps of dynamical systems and do not increase the dimensions.

Our result was inspired by the fact of finite vocabulary in natural languages, where V can be mimicked to a "vocabulary", H_1 and H_2 to "phrases", and \mathcal{H}_V to "sentences". Our results provide a linguistic aspect for composite mappings, and we hope our findings will in turn inspire related research in linguistics.

It should be noted that this paper focuses on the existence of a finite vocabulary and the constructed V in Eq. (8) is not optimal. If a sequential composition of mappings in such V is used to approximate functions in practical applications, the required sequence length may be extremely large. However, in practical applications, it is often only necessary to approximate a certain small set of continuous functions, hence designing an efficient vocabulary for them would be a fascinating future direction.

A Additional lemmas

It is well known that an ODE system can be approximated by many numerical methods. Particularly, we use the splitting approach [21]. Let v(x, t) be the summation of several functions,

$$v(x,t) = \sum_{j=1}^{J} v_j(x,t), J \in \mathbb{Z}_+.$$
(33)

For a given time step Δt , we define the iteration as

$$x_{k+1} = T_k x_k = T_k^{(J)} \circ \dots \circ T_k^{(2)} \circ T_k^{(1)} x_k,$$
(34)

where the map $T_k^{(j)}: x \to y$ is

$$y \equiv T_k^{(j)}(x) = x + \Delta t v_j(x, t_k) \quad t_k = k \Delta t.$$
(35)

Lemma A.1. Let all $v_j(x,t)$, j = 1, 2, ..., J, and v(x,t), $(x,t) \in \mathbb{R}^d \times [0, \tau]$, be piecewise constant (w.r.t. t) and L-Lipschitz (L > 0). Then, for any $\tau > 0$, $\varepsilon > 0$ and x_0 in a compact domain Ω , there exist a positive integer n and $\Delta t = \tau/n < 1$ such that $||x(\tau) - x_n|| \le \varepsilon$.

Proof. Without loss of generality, we only consider J = 2. (The general J case can be proven accordingly.) In addition, we assume v_j are constant w.r.t. t in each interval $[t_k, t_{k+1})$ the time step, *i.e.* $v(x,t) = v(x,t_k), t \in [t_k, t_{k+1})$. This can be arrived at by choosing small enough Δt and adjusting the time step to match the piecewise points of v_j . Thus, we have

$$\begin{aligned} x_{k+1} &= T_k^{(2)}(x_k + \Delta t v_1(x_k, t_k)) \\ &= x_k + \Delta t v_1(x_k, t_k) + \Delta t v_2(x_k + \Delta t v_1(x_k, t_k), t_k) \\ &= x_k + \Delta t (v_1(x_k, t_k) + v_2(x_k, t_k)) + \Delta t^2 R_k. \end{aligned}$$

Since $v_i(x, t)$ are Lipschitz, the residual term R_k is bounded by a constant R that is independent of k. In fact, we have

$$\begin{aligned} \|R_k\| &= \|v_2(x_k + \Delta t v_1(x_k, t_k), t_k) - v_2(x_k, t_k)\| / \Delta t \\ &\leq L \|v_1(x_k, t_k)\| \leq L(\|v_1(0, t_k)\| + L\|x_k\|). \end{aligned}$$

Let $V := \sup\{||v_j|| | t \in (0, \tau)\}, X := \sup\{||x_0|| | x_0 \in \Omega\}$, then we have

$$\|x_{k+1}\| \le (1 + L\Delta t) \|x_k\| + \Delta t^2 L(V + L\|x_k\|).$$
(36)

As a result, $||x_k||$ is bounded by $B := (X + \frac{V\Delta t}{1+L})e^{L(1+L)\tau}$ and $||R_k||$ is bounded by R := L(V + LB).

Using the integral form of the ODE and defining the error as $e_k := x_k - x(t_k)$, we have the following estimation:

$$\begin{aligned} \|e_{k+1}\| &= \|e_k + \int_{t_k}^{t_{k+1}} (v(x_k, t_k) - v(x(t), t))dt + R_k \Delta t^2 \| \\ &\leq \|e_k\| + \int_{t_k}^{t_{k+1}} \|v(x(t), t_k) - v(x_k, t_k)\|dt + \|R_k\| \Delta t^2 \\ &\leq (1 + L\Delta t) \|e_k\| + R\Delta t^2. \end{aligned}$$

Employing the inequality $(1 + L\Delta t)^k \leq e^{Lk\Delta t} \leq e^{L\tau}$ and the initial error $e_0 = 0$, we have

$$\|e_k\| \le (1 + L\Delta t)^k \|e_0\| + \frac{R\Delta t^2}{L\Delta t} [(1 + L\Delta t)^k - 1] \le R\Delta t (e^{L\tau} - 1)/L.$$
(37)

For any $\varepsilon > 0$, let $n \ge \left[\frac{R\tau e^{L\tau}}{L\varepsilon}\right]$, then we have $||x(t_k) - x_k|| \le \varepsilon$, which finishes the proof.

B Proofs of lemmas and propositions

B.1 Proof of Lemma 2.7

Lemma 2.7. Let map $T = F_1 \bullet ... \bullet F_n$ be a composition of n continuous functions F_i defined on an open domain D_i , and let \mathcal{F} be a continuous function class that can uniformly approximate each F_i on any compact domain $\mathcal{K}_i \subset D_i$. Then, for any compact domain $\mathcal{K} \subset D_1$ and $\varepsilon > 0$, there are n functions $\tilde{F}_1, ..., \tilde{F}_n$ in \mathcal{F} such that

$$\|T(x) - \tilde{F}_1 \bullet \dots \bullet \tilde{F}_n(x)\| \le \varepsilon, \quad \forall x \in \mathcal{K}.$$
(38)

Proof. It is enough to prove the case of n = 2. (The case of n > 2 can be proven by the method of induction, as T can be expressed as the composition of two functions, $T = F_n \circ T_{n-1}$, with $T_{n-1} = F_{n-1} \circ ... \circ F_1$.) According to the definition, we have $F_1(D_1) \subset D_2$. Since D_2 is open and $F_1(\mathcal{K})$ is compact, we can choose a compact set $\mathcal{K}_2 \subset D_2$ such that $\mathcal{K}_2 \supset \{F_1(x) + \delta_0 y : x \in \mathcal{K}, \|y\| < 1\}$ for some $\delta_0 > 0$ that is sufficiently small.

According to the continuity of F_2 , there is a $\delta \in (0, \delta_0)$ such that

$$||F_2(y) - F_2(y')|| \le \varepsilon/2, \forall y, y' \in \mathcal{K}_2,$$

provided $||y - y'|| \le \delta$. The approximation property of \mathcal{F} allows us to choose $\tilde{F}_1, \tilde{F}_2 \in \mathcal{F}$ such that

$$\begin{aligned} \|\tilde{F}_1(x) - F_1(x)\| &\leq \delta < \delta_0, \quad \forall x \in \mathcal{K}, \\ \|\tilde{F}_2(y) - F_2(y)\| &\leq \varepsilon/2, \quad \forall y \in \mathcal{K}_2. \end{aligned}$$

As a consequence, for any $x \in \mathcal{K}$, we have $F_1(x), \tilde{F}_1(x) \in \mathcal{K}_2$ and

$$||F_2 \circ F_1(x) - \tilde{F}_2 \circ \tilde{F}_1(x)|| \le ||F_2 \circ F_1(x) - F_2 \circ \tilde{F}_1(x)|| + ||F_2 \circ \tilde{F}_1(x) - \tilde{F}_2 \circ \tilde{F}_1(x)|| \le \varepsilon/2 + \varepsilon/2 = \varepsilon.$$

B.2 Proof of Proposition 3.1

Proposition 3.1. (1) Let Q be a nonsingular matrix. If $x \to Wx$ is an affine flow map then the map $x \to QWQ^{-1}x$, $x \to W^T x$ and $x \to W^{-1}x$ also are. (2) Let U be an upper triangular matrix below with $\lambda > 0$, then the map $x \to Ux$ is an affine flow map for arbitrary vector $w_{2:d}$,

$$U = \begin{pmatrix} \lambda & w_{2:d} \\ 0 & I_{d-1} \end{pmatrix}.$$
(39)

Proof. (1) It is because $\ln(QWQ^{-1}) = Q\ln(W)Q^{-1}$, $\ln(W^T) = \ln(W)^T$ and $\ln(W^{-1}) = -\ln(W)$ are real as $\ln(W)$ is real. (2) It can be obtained by employing the formula,

$$\ln \begin{pmatrix} \lambda & w_{2:d} \\ 0 & I_{d-1} \end{pmatrix} = \begin{pmatrix} \ln(\lambda) & \frac{\ln(\lambda)}{\lambda - 1} w_{2:d} \\ 0 & 0 \end{pmatrix}, \quad \lambda \neq 1.$$
(40)

When $\lambda = 1$, the formula is simplified as $\ln(U) = U - I_d$.

B.3 Proof of Proposition 3.2

Proposition 3.2. If $\tilde{\alpha}, \tilde{\beta} \in (0, \infty)^d$, then the map $\sum_{\tilde{\alpha}, \tilde{\beta}}$ is a leaky-ReLU flow map.

Proof. By directly calculate the flow map $\phi_{\Sigma_{\alpha,\beta}(x)}^{\tau}$ with $\alpha, \beta \in \mathbb{R}^d$, we have

$$\phi_{\Sigma_{\alpha,\beta}(x)}^{\tau}(x) = \Sigma_{\tilde{\alpha},\tilde{\beta}}(x), \tag{41}$$

where $\tilde{\boldsymbol{\alpha}} = (e^{\tau \alpha_1}, ..., e^{\tau \alpha_d})$ and $\tilde{\boldsymbol{\beta}} = (e^{\tau \beta_1}, ..., e^{\tau \beta_d})$. Choosing $\alpha_i = \ln(\tilde{\alpha}_i), \beta_i = \ln(\tilde{\beta}_i)$ and $\tau = 1$, we can finish the proof.

B.4 Proof of Lemma 3.4

Theorem 3.3. (Lie product formula) For all matrix $A, B \in \mathbb{R}^{d \times d}$, we have

$$e^{A+B} = \lim_{n \to \infty} \left(e^{A/n} e^{B/n} \right)^n = \lim_{n \to \infty} \left(\phi_{Ax}^{1/n} \bullet \phi_{Bx}^{1/n} \right)^{\bullet n} \tag{42}$$

Proof. The proof can be found in [18].

Lemma 3.4.Let $v_i : \mathbb{R}^d \to \mathbb{R}^d$, i = 1, 2, ..., m be Lipschitz continuous funcitons, $v = \sum_{i=1}^m v_i$, Ω be a compact domain. For any t > 0 and $\varepsilon > 0$, there is a positive integers n, such that the flow map ϕ_v^t can be approximated by composition of flow maps $\phi_{v_i}^{t/n}$, i.e.

$$\|\phi_v^t(x) - \left(\phi_{v_1}^{t/n} \bullet \phi_{v_2}^{t/n} \bullet \dots \bullet \phi_{v_m}^{t/n}\right)^{\bullet n}(x)\| < \varepsilon, \quad \forall x \in \Omega.$$
(43)

Proof. It's a special case of Lemma A.1 with a velocity field v_i independent on t.

B.5 Proof of Lemma 3.6

Theorem 3.5. (Kronecker's approximation theorem) Let $\gamma \in \mathbb{R}$ be an irrational number, then for any $t \in \mathbb{R}$ and $\varepsilon > 0$, there exist two integers p and q with q > 0, such that $|\gamma q + p - t| < \varepsilon$.

Proof. The proof can be found in [2].

Lemma 3.6. Let $v : \mathbb{R}^d \to \mathbb{R}^d$ be a Lipschitz continuous function, Ω be a compact domain. For any t > 0 and $\varepsilon > 0$, there exist two positive integers p and q, such that the flow map ϕ_v^t can be approximated by $(\phi_v^1)^{\bullet p} \bullet (\phi_{-v}^{-2})^{\bullet q}$, i.e.

$$\|\phi_v^t(x) - (\phi_v^1)^{\bullet p} \bullet (\phi_{-v}^{\sqrt{2}})^{\bullet q}(x)\| < \varepsilon, \quad \forall x \in \Omega.$$
(44)

Proof. Since the field v is Lipschitz and the domain Ω is compact, there exist a constant C > 0 such that

$$\|\phi_v^{t_2}(x_0) - \phi_v^{t_1}(x_0)\| \le \int_{t_1}^{t_2} \|v(x(t))\| dt < C|t_2 - t_1|, \quad \forall x_0 \in \Omega.$$
(45)

Employing the Kronecker's Theorem 3.5 with $\gamma = -\sqrt{2}$, approximating t by $p - q\sqrt{2}$ such that

$$|p - q\sqrt{2} - t| < \varepsilon/C,\tag{46}$$

then we have

$$\|\phi_v^t(x) - \phi_v^{p-q\sqrt{2}}(x)\| < \varepsilon, \quad \forall x \in \Omega.$$
(47)

As t is positive, we have p is positive as q is. The following representation of the flow maps finishes the proof,

$$\phi_v^{p-q\sqrt{2}} = \phi_v^p \bullet \phi_v^{-q\sqrt{2}} = \phi_v^p \bullet \phi_{-v}^{q\sqrt{2}} = (\phi_v^1)^{\bullet p} \bullet (\phi_{-v}^{\sqrt{2}})^{\bullet q}.$$
(48)

Corollary 3.7. For any flow maps h in $H_1 \cup H_2$, $\varepsilon > 0$ and compact domain $\Omega \subset \mathbb{R}^d$, there is a sequence $\phi_1, \phi_2, ..., \phi_m$ in V (Eq. 8) such that

$$\|h(x) - (\phi_1 \bullet \phi_2 \dots \bullet \phi_m)(x)\| < \varepsilon, \quad \forall x \in \Omega.$$
(49)

Proof. The proof is finished by directly employing Lemma 3.4 and Lemma 3.6 with the following splittings,

$$Ax + b = \sum_{i=1}^{d} \sum_{j=1}^{d} a_{ij} E_{ij} x + \sum_{i=1}^{d} b_i e_i, \quad \Sigma_{\alpha,\beta}(x) = \sum_{i=1}^{d} \alpha_i \Sigma_{e_i,0}(x) + \sum_{i=1}^{d} \beta_i \Sigma_{0,e_i}(x).$$
(50)

B.6 Proof of Lemma 4.2

Lemma 4.2. Let $\alpha > 0$ and $\max(1/\alpha, \alpha)|aw_d| < 1$, then the map T in Eq. (29) is a composition of at most six flow maps in $H_1 \cup H_2$.

Proof. Recall the map $T: x \to y$ is of the form

$$T: \begin{cases} y^{(i)} = x^{(i)}, i = 1, \cdots, d-1, \\ y^{(d)} = x^{(d)} + a\sigma(w_1 x^{(1)} + \dots + w_d x^{(d)} + b). \end{cases}$$
(51)

where $\sigma = \sigma_{\alpha}$ is the leaky-ReLU function, $a, b, w_1, ..., w_d \in \mathbb{R}$ are parameters. We construct the composition flow maps in three cases.

(1) The case of $w_1 = ... = w_d = 0$. In this case, T is already an affine flow map in H_1 .

(2) The case of $w_1 = ... = w_{d-1} = 0, w_d \neq 0$. In this case, we only need to consider the last coordinate as the first d - 1 coordinates are kept. According to

$$y^{(d)} = x^{(d)} + a\sigma_{\alpha}(w_d x^{(d)} + b) = (x^{(d)} + \frac{b}{w_d}) + a\sigma_{\alpha}(w_d(x^{(d)} + \frac{b}{w_d})) - \frac{b}{w_d},$$
 (52)

we can assume b = 0 as it can be absorbed in an affine flow map. Let $\tilde{\alpha} = 1 + \alpha a w_d > 0$, $\tilde{\beta} = 1 + a w_d > 0$, as $\max(1/\alpha, \alpha) |a w_d| < 1$, we have the following representation,

$$x^{(d)} + a\sigma_{\alpha}(w_d x^{(d)}) = \begin{cases} \sigma_{\tilde{\alpha},\tilde{\beta}}(x^{(d)}), & w_d < 0, \\ \sigma_{\tilde{\beta},\tilde{\alpha}}(x^{(d)}), & w_d > 0, \end{cases}$$
(53)

which is a leaky-ReLU flow map in H_3 either $w_d > 0$ or $w_d < 0$.

(3) The case of $w_i \neq 0$ for some i = 1, ..., d - 1. We only show the case of $w_1 \neq 0$ without loss of generality. Same with (1), we can absorb b in $x^{(1)}$ using an affine flow map; hence we only need to consider the case of b = 0. In addition, using the property of leaky-ReLU,

$$\sigma_{\alpha}(x) = -\alpha \sigma_{1/\alpha}(-x) \tag{54}$$

 $\sigma_{\alpha}(x) = -\alpha \sigma_{1/\alpha}(-x)$, we can further assume $w_1 > 0$. (If $w_1 < 0$, we change w to -w, α to $1/\alpha$, a to $a\alpha$, which does not change the map T). As a result, the map T can be represented by the following composition,

$$T(x) = F_0 \bullet F_1 \bullet \dots \bullet F_5(x), \tag{55}$$

where each composition step is as follows,

$$\begin{pmatrix} x^{(1)} \\ x^{(2:d-1)} \\ x^{(d)} \end{pmatrix} \xrightarrow{F_0} \begin{pmatrix} \nu \\ x^{(2:d-1)} \\ x^{(d)} \end{pmatrix} \xrightarrow{F_1} \begin{pmatrix} \sigma(\nu) \\ x^{(2:d-1)} \\ x^{(d)} \end{pmatrix} \xrightarrow{F_2} \begin{pmatrix} \sigma(\nu) \\ x^{(2:d-1)} \\ x^{(d)} + a\sigma(\nu) \end{pmatrix} \xrightarrow{F_3} \begin{pmatrix} \nu \\ x^{(2:d-1)} \\ x^{(d)} + a\sigma(\nu) \end{pmatrix} \xrightarrow{F_5} \begin{pmatrix} x^{(1)} \\ x^{(2:d-1)} \\ x^{(d)} + a\sigma(\nu) \end{pmatrix}.$$

Here, $\nu := w_1 x^{(1)} + \cdots + w_d x^{(d)}$ and $x^{(2:d-1)}$ represent the elements $x^{(2)}, ..., x^{(d-1)}$. We clarify that each component $F_i, i = 0, \cdots, 5$, are flow maps in $H_1 \cup H_2$.

In fact, $F_0, F_2, F_5 = F_0^{-1}$ are affine transformations,

$$F_0(x) = \begin{pmatrix} w_1 & w_{2:d} \\ 0 & I_{d-1} \end{pmatrix} x, \quad F_2(x) = \begin{pmatrix} I_{d-1} & 0 \\ (a, 0_{2:d-1}) & 1 \end{pmatrix} x, \quad F_5(x) = \begin{pmatrix} 1/w_1 & -w_{2:d}/w_1 \\ 0 & I_{d-1} \end{pmatrix} x$$

where I_{d-1} is the identity matrix, $(a, 0_{2:d-1}) = (a, 0, ..., 0)$ with d-2 zeros. According to Proposition 3.1, they are flow maps in H_1 . In addition, F_1, F_3 and F_4 are leaky-ReLU flow maps in H_2 as

$$F_1 = \Sigma_{(\alpha, 1_{2:d}), 1_{1:d}}, \quad F_3 = \Sigma_{(1/\alpha, 1_{2:d}), 1_{1:d}}, \quad F_4 = \Sigma_{(1+w_d a \alpha, 1_{2:d}), (1+w_d a, 1_{2:d})}.$$
 (56)

Here, the condition $\max(1/\alpha, \alpha)|aw_d| < 1$ is used to ensure $1 + w_d a \alpha > 0$ and $1 + w_d a > 0$, no matter whether Eq. (54) is used.

C Proof of the main theorems

C.1 Proof of Theorem 4.1

Theorem 4.1. Let $\Psi \in Diff_0(\Omega)$ be an orientation preserving diffeomorphism, Ω be a compact domain $\Omega \subset \mathbb{R}^d$. Then, for any $\varepsilon > 0$, there is a sequence of transformations, $T_k^{(i,j)}$, is of the form Eq. (28) such that

$$\|\Psi(x) - (T_1^{(1,1)} \bullet T_1^{(1,2)} \bullet \dots \bullet T_1^{(N,d)} \bullet \dots \bullet T_n^{(1,1)} \bullet T_n^{(1,2)} \bullet \dots \bullet T_n^{(N,d)})(x)\| \le \varepsilon, \quad \forall x \in \Omega.$$

Proof. (1) Firstly, employed results of [1; 8], any OP diffeomorphism Ψ can be approximated by flow map of ODEs. Particularly, we can choose the ODEs as neural ODEs are of the form

$$x'(t) = v(x(t), t) = \sum_{i=1}^{N} s_i(t)\sigma(w_i(t) \cdot x(t) + b_i(t)),$$
(57)

where the field function v is a neural network with N hidden neurons, the activation is chosen as the leaky-ReLU function $\sigma = \sigma_{\alpha}$ for some $\alpha \in (0, 1)$, $s_i \in \mathbb{R}^d$, $w_i \in \mathbb{R}^d$ and $b_i \in \mathbb{R}$ are piecewise constant functions of t. The universal approximation property of neural networks [12] implies that, for any $\varepsilon > 0$, there exist $s_i \in \mathbb{R}^d$, $w_i \in \mathbb{R}^d$, $b_i \in \mathbb{R}$, $\tau > 0$ and $N \in \mathbb{Z}_+$, such that

$$\|\Psi(x) - \phi_v^{\tau}(x)\| < \varepsilon/2, \quad \forall x \in \Omega,$$
(58)

where ϕ_v^{τ} is the flow map of Eq. (57).

(2) Following the approach of [16], we employ a proper splitting numerical scheme to discretize the neural ODE (57). Split the field v as a summation of Nd functions, $v(x,t) = \sum_{i=1}^{N} \sum_{j=1}^{d} v_{ij}(x,t)e_j$, where e_j is the *j*-th axis unit vector and $v_{ij}(x,t) = s_{ij}(t)\sigma(w_i(t)\cdot x+b_i(t))$ are scalar Lipschitz functions. Then Lemma A.1 implies that there is a $n \in \mathbb{Z}_+$ big enough such that

$$\|\phi_v^{\tau}(x) - \Phi(x)\| < \varepsilon/2, \quad \forall x \in \Omega,$$
(59)

where

$$\Phi = T_1 \bullet \dots \bullet T_n \equiv (T_1^{(1,1)} \bullet T_1^{(1,2)} \bullet \dots \bullet T_1^{(N,d)}) \bullet \dots \bullet (T_n^{(1,1)} \bullet T_n^{(1,2)} \bullet \dots \bullet T_n^{(N,d)}),$$

and the map $T_k^{(i,j)}: x \to y$ is of the form

$$\begin{cases} y^{(l)} = x^{(l)}, l \neq j, \\ y^{(j)} = x^{(j)} + \Delta t v_{ij}(x, k\Delta t). \end{cases}$$
(60)

Here, the superscript in $x^{(l)}$ indicates the *l*-th coordinate of *x*.

(3) Combining the above two parts, we finish the proof.

C.2 Proof of Theorem 4.3

Theorem 4.3. Let $\Psi \in Diff_0(\Omega)$ be an orientation preserving diffeomorphism, Ω be a compact domain $\Omega \subset \mathbb{R}^d$. Then, for any $\varepsilon > 0$, there is a sequence of flow maps, $h_1, h_2, ..., h_m, m \in \mathbb{Z}_+$, in $H = H_1 \cup H_2$ such that

$$\|\Psi(x) - (h_1 \bullet h_2 \bullet \dots \bullet h_m)(x)\| \le \varepsilon, \quad \forall x \in \Omega.$$
(61)

Proof. According to Theorem 4.1, there is a sequence of transformations, $T_k^{(i,j)}$, is of the form Eq. (28) such that

$$\|\Psi(x) - (T_1^{(1,1)} \bullet T_1^{(1,2)} \bullet \dots \bullet T_1^{(N,d)} \bullet \dots \bullet T_n^{(1,1)} \bullet T_n^{(1,2)} \bullet \dots \bullet T_n^{(N,d)})(x)\| \le \varepsilon, \quad \forall x \in \Omega.$$

Here *n* can be choosed large enough such that $\max(1/\alpha, \alpha)C^2\Delta t < 1, \Delta t = \tau/n$, where

$$C = \max_{t \in [0,\tau]} \left\{ |s_{ij}(t)|, |w_{ij}(t)| \mid i, j = 1, 2, ..., d \right\}.$$
(62)

Since s_i, w_i are piecewise constant functions, the constant C is finite. Then according to Lemma 4.2, each $T_k^{(i,j)}$ is a composition of at most six flow maps in $H_1 \cup H_2$. As a consequence, we finish the proof by relabelling the index of the used flow maps.

C.3 Proof of Theorem 2.6

Theorem 2.6. Let $\Psi \in Diff_0(\Omega)$ be an orientation preserving diffeomorphism, Ω be a compact domain $\Omega \subset \mathbb{R}^d$. Then, for any $\varepsilon > 0$, there is a sequence of flow maps, $\phi_1, \phi_2, ..., \phi_n \in V, n \in \mathbb{Z}_+$, such that

$$\|\Psi(x) - (\phi_1 \bullet \phi_2 \bullet \dots \bullet \phi_n)(x)\| \le \varepsilon, \quad \forall x \in \Omega.$$
(63)

Proof. (1) According to Theorem 4.3, there is a sequence of flow maps, $h_1, h_2, ..., h_m, m \in \mathbb{Z}_+$, in $H = H_1 \cup H_2$ such that

$$\|\Psi(x) - (h_1 \bullet h_2 \bullet \dots \bullet h_m)(x)\| \le \varepsilon/2, \quad \forall x \in \Omega.$$
(64)

(2) According to Corollary 3.7, each h_i can be universal approximation by \mathcal{H}_V , *i.e.*, for any $\varepsilon_i > 0$ and compact domain Ω_i , there is a sequence of flow maps, $\phi_{i,1}, ..., \phi_{i,n_i} \in V$, such that

$$\|h_i(x) - (\phi_{i,1} \bullet \phi_{i,2} \bullet \dots \bullet \phi_{i,n_i})(x)\| \le \varepsilon_i, \quad \forall x \in \Omega_i.$$
(65)

(3) According to Lemma 2.7, we can choose $\phi_{i,j} \in V$ and reindex them as $\phi_1, \phi_2, ..., \phi_n$ such that $\|(h_1 \bullet h_2 \bullet ... \bullet h_m)(x) - (\phi_1 \bullet \phi_2 \bullet ... \bullet \phi_n)(x)\| \leq \varepsilon/2, \quad \forall x \in \Omega.$ (66)

(4) Combining (1) and (3), we finish the proof.

C.4 **Proof of Theorem 2.2**

Theorem 2.2. Let $\Omega \subset \mathbb{R}^d$ be a compact domain. Then, there is a finite set $V \subset Diff_0(\mathbb{R}^d)$ such that the hypothesis space \mathcal{H}_V in Eq. (2) has C-UAP for $Diff_0(\mathbb{R}^d)$.

Proof. The Theorem 2.6 provides constructive proof for the existence of V in Eq. (8).

Corollary 2.3. Let $\Omega \subset \mathbb{R}^d$ be a compact domain, $d \geq 2$ and $p \in [1, +\infty)$. Then, there is a finite set $V \subset C(\mathbb{R}^d, \mathbb{R}^d)$ such that the hypothesis space \mathcal{H}_V in Eq. (2) has L^p -UAP for $C(\mathbb{R}^d, \mathbb{R}^d)$.

Proof. We can use the same V in Theorem 2.2 as $V \subset \text{Diff}_0(\mathbb{R}^d) \subset C(\mathbb{R}^d, \mathbb{R}^d)$.

(1) Let $f \in C(\mathbb{R}^d, \mathbb{R}^d), d \geq 2$, then the result of [5] indicates that for any $\varepsilon > 0$, there is a OP diffeomorphism $\Psi \in \text{Diff}_0(\mathbb{R}^d)$ such that

$$\|f - \Psi\|_{L^p(\Omega)} < \varepsilon/2. \tag{67}$$

(2) The Theorem 2.2 indicates that, there is mapping $\Phi \in \mathcal{H}_V$ such that

$$\|\Psi(x) - \Phi(x)\| < \varepsilon' = \frac{\varepsilon}{2|\Omega|}, \quad \forall x \in \Omega.$$
(68)

(3) Combining (1) and (2), we have

$$\|f - \Phi\|_{L^p(\Omega)} < \varepsilon. \tag{69}$$

which finishes the proof.
