# Robust Exponential Stability and Invariance Guarantees with General Dynamic O'Shea-Zames-Falb Multipliers * 

Carsten W. Scherer *<br>* Department of Mathematics, University of Stuttgart, Germany, e-mail: carsten.scherer@imng.uni-stuttgart.de

#### Abstract

We propose novel time-domain dynamic integral quadratic constraints with a terminal cost for exponentially weighted slope-restricted gradients of not necessarily convex functions. This extends recent results for subdifferentials of convex function and their link to so-called O'Shea-Zames-Falb multipliers. The benefit of merging time-domain and frequencydomain techniques is demonstrated for linear saturated systems.

Keywords: Robustness analysis; Convex optimization; Uncertain systems; Dissipativity; Integral quadratic constraints.

## 1. INTRODUCTION

We consider the stability analysis of a loop with a discretetime linear time-invariant (LTI) system

$$
\begin{equation*}
x_{t+1}=A x_{t}+B w_{t}, z_{t}=C x_{t}+D w_{t} \tag{1}
\end{equation*}
$$

(were $A \in \mathbb{R}^{n \times n}$ ) in feedback with a gradient nonlinearity

$$
\begin{equation*}
w_{t}=\nabla f\left(z_{t}\right) \tag{2}
\end{equation*}
$$

with a differentiable function $f: \mathbb{R}^{d} \rightarrow \mathbb{R}$ and for $t \in \mathbb{N}_{0}$. It is by now well-established how the stability properties of such interconnections relate to the convergence analysis of optimization algorithms (Lessard et al., 2016) or the safety verification of neural networks (Fazlyab et al., 2019).
The general goal in this paper is to characterize robust exponential stability for the state as well as ellipsoidal invariance for the output of (1) if the gradients are sloperestricted to $[m, L] \subset \mathbb{R}$ (Freeman, 2018; Gramlich et al., 2022; Rotaru et al., 2022). With the left-shift operator $(\sigma x)(t):=x(t+1)$, systems like (1) are also described as $\sigma x=A x+B w, z=C x+D w$. Similarly, (2) reads as $w=\nabla f(z)$ with $\nabla f(z)_{t}:=\nabla f\left(z_{t}\right)$ for $t \in \mathbb{N}_{0}$.

We rely on a discrete-time version of the stability results based on integral quadratic constraints (IQCs) as surveyed in Scherer (2022a). This proceeds as follows. With a filter

$$
\begin{equation*}
\sigma \xi=A_{\Psi} \xi+B_{\Psi}\binom{z}{w}, v=C_{\Psi} \xi+D_{\Psi}\binom{z}{w}, \xi_{0}=0 \tag{3}
\end{equation*}
$$

and a symmetric matrix $P$, one assures that the response of (3) driven by the trajectories of (2) satisfies the IQC

$$
\begin{equation*}
\sum_{t=0}^{T-1} v_{t}^{\top} P v_{t} \geq 0 \text { for all } T \in \mathbb{N} . \tag{4}
\end{equation*}
$$

In addition, one verifies that the series interconnection of the given system (1) and the filter (3) is strictly dissipative

[^0]with respect to the supply rate $v \mapsto-v^{\top} P v$ and with a positive definite storage function. Classical dissipativity arguments then guarantee the existence of a constant $c$ such that
\[

$$
\begin{equation*}
\sum_{t=0}^{T-1}\left\|x_{t}\right\|^{2} \leq c^{2}\left\|x_{0}\right\|^{2} \text { for all } T \in \mathbb{N} \tag{5}
\end{equation*}
$$

\]

uniformly for all trajectories of the interconnection (1)-(2). If $\Psi$ is the transfer matrix of $(3), \Psi^{*} P \Psi$ is then said to be the dynamic multiplier which assures stability of the loop.
Specifically, we use general O'Shea-Zames-Falb (OZF) multipliers (Willems and Brockett, 1968; Fetzer and Scherer, 2017a; Carrasco et al., 2020) and their extension to prove exponential stability (Boczar et al., 2015; Hu and Seiler, 2016; Freeman, 2018; Michalowsky et al., 2021). The paper by Hu and Seiler (2016) nicely emphasizes the discrepancy between time-domain and frequency domain proofs (and the underlying technical delicacies), related to the fact that storage functions as emerging from frequency domain conditions through the application of the Kalman-Yakubovich-Popov Lemma are in general not sign-definite.

The specific technical contribution of this paper is to overcome this discrepancy. We propose novel IQCs for slope-restricted gradients, which extends (4) to include, on the right, a nontrivial terminal cost $\xi_{T} Z \xi_{T}$ involving the filter's state at the end time of the interval $[0, T] \cap \mathbb{N}_{0}$. As argued by Scherer and Veenman (2018) and Scherer (2022a,b), this concept leads to a complete (non-conservative) resolution of the dichotomy between time-domain and frequency-domain IQC results, which involves a storage function with a positivity condition that is coupled to the terminal cost matrix $Z$. It is beyond the scope of this paper to prove that our construction is tight.
Another goal of the paper is to build these IQCs in a direct insightful fashion, even for gradients of functions that are not necessarily convex. We avoid technical delicacies about smoothness or invertibility of gradient maps (Freeman, 2018), or about unboundedness of multipliers, which pre-
vents the use of standard IQC results (Michalowsky et al., 2021). This paper extends the results in (Scherer, 2022b) that were confined to merely convex functions, and resolves the troubles that emerge in the continuous-time setting as discussed by Fetzer and Scherer (2017b).
One way to investigate exponential convergence properties of feedback loops uses the exponential weighting map

$$
T_{\rho}\left(z_{0}, z_{1}, z_{2}, \ldots\right)=\left(\rho^{0} z_{0}, \rho^{1} z_{1}, \rho^{2} z_{2}, \ldots\right) .
$$

for some $\rho \in(0,1)$ (Desoer and Vidyasagar, 1975). Clearly, $T_{\rho}$ is linear and invertible with $T_{\rho}^{-1}=T_{\rho^{-1}}$. It is easily checked that the set of trajectories $(x, w, z)$ of (1) are in one-to-one correspondence with trajectories $(\bar{x}, \bar{w}, \bar{z})$ of

$$
\begin{equation*}
\sigma \bar{x}=\left(\rho^{-1} A\right) \bar{x}+\left(\rho^{-1} B\right) \bar{w}, \quad \bar{z}=C \bar{x}+D \bar{w} \tag{6}
\end{equation*}
$$

under the transformations $\bar{x}=T_{\rho^{-1}} x, \bar{w}=T_{\rho^{-1}} w$, and $\bar{z}=T_{\rho^{-1}} z$. Similarly, (2) translates into

$$
\begin{equation*}
\bar{w}=\Delta_{\rho}^{f}(\bar{z}) \tag{7}
\end{equation*}
$$

with the static time-varying operator defined as

$$
\begin{equation*}
\Delta_{\rho}^{f}(\bar{z})_{t}:=\left(\rho^{-t} \nabla f\left(\rho^{t} \bar{z}_{t}\right)\right)_{t} \text { for } t \in \mathbb{N}_{0} \tag{8}
\end{equation*}
$$

Ensuring (5) for the transformed loop then guarantees that the state-trajectory of the original loop (1)-(2) converges exponentially to zero with rate $\rho$. Additional ellipsoidal invariance properties can be assured by suitable dissipativity arguments.
The remaining paper is structured as follows. In Section 2 , we introduce the subdifferential of non-convex slope-restricted functions and a key dissipation inequality. In Section 3, this is used to propose static quadratic constraints for lifted functions, which leads to dynamic IQCs with a non-zero terminal cost as seen in Section 4. In Section 5, these are used to demonstrate how to robustly guarantee amplitude bounds for signals in feedback interconnections, while Section 6 exhibits the benefit over existing results with a concrete numerical example.

Notation. Any tupel $x \in\left(\mathbb{R}^{n}\right)^{p}$ is represented as $x=$ $\left(x_{1}, \ldots, x_{p}\right)$ and $\operatorname{col}(x)=\operatorname{col}(x):=\left(x_{1}^{\top}, \ldots, x_{p}^{\top}\right)^{\top}$ stacks the entries of the tupel into a column vector. A matrix $A \in \mathbb{R}^{n \times n}$ is doubly hyperdominant (d.h.d.) if all its offdiagonal elements are non-positive and if $A e \geq 0$ and $e^{\top} A \geq 0$ holds, where $e \in \mathbb{R}^{n}$ is the the all-ones vector (Willems and Brockett, 1968). For $A, B \in \mathbb{R}^{n \times n}, A \prec B$ means that $A$ and $B$ are symmetric and $B-A$ is positive definite. We denote by $\|x\|^{2}:=x^{\top} x$ the Euclidean norm of $x \in \mathbb{R}^{d}$. Moreover, $l_{2 e}^{d}$ is the space of all sequences $x: \mathbb{N}_{0} \rightarrow \mathbb{R}^{d}$, with $l_{2}^{d}$ denoting the subspace of all $x \in l_{2 e}^{d}$ with $\|x\|_{2}^{2}:=\sum_{t=0}^{\infty}\left\|x_{t}\right\|^{2}<\infty$. For $h \in \mathbb{N}$, the truncation and lifting operation of some signal $x=\left(x_{0}, x_{1}, \ldots\right) \in l_{2 e}^{d}$ is defined and denoted as $x^{h}:=\operatorname{col}\left(x_{0}, \ldots, x_{h-1}\right)$.

## 2. ON SLOPE-RESTRICTED MAPS

Recall that $f: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is $m$-strongly convex for $m>0$ if $f-m q$ is convex where $q(x)=\frac{1}{2}\|x\|^{2}$. For $d=1$ and if $f$ is two times continuously differentiable, this means that the slope of $f^{\prime}$ is bounded from below as $f^{\prime \prime}(x) \geq m$ for all $x \in \mathbb{R}$. It is natural to extend this definition to nonpositive values of $m$ and to upper bounds on the slope as follows. Definition 1. Let $\sigma \in \mathbb{R}$ and $f: \mathbb{R}^{d} \rightarrow \mathbb{R}$ be any function. Then $f$ is called $\sigma$-convex if $f_{\sigma}:=f-\sigma q$ is convex.

Moreover, $f$ is called $\sigma$-concave if $f^{\sigma}:=\sigma q-f$ is convex. The set of functions $f: \mathbb{R}^{d} \rightarrow \mathbb{R}$ which are both $m$-convex and $L$-concave is denoted by $\mathcal{S}_{m, L}$.

For smooth functions, this class has been also considered by Freeman (2018); Gramlich et al. (2022); Rotaru et al. (2022). In the sequel, we collect some observations without assumptions on differentiability.
For $\sigma_{1}, \sigma_{2} \in \mathbb{R}$, we will tacitly use the properties

$$
\begin{equation*}
f_{\sigma_{1}}-f_{\sigma_{2}}=f_{\sigma_{1}}+f^{\sigma_{2}}=f^{\sigma_{2}}-f^{\sigma_{1}}=\left(\sigma_{2}-\sigma_{1}\right) q \tag{9}
\end{equation*}
$$

If $f \in \mathcal{S}_{m, L}$, then $f_{m}+f^{L}=(L-m) q$ is convex, which implies $L \geq m$.
We extend the notation in Definition 1 to the sets $\mathcal{S}_{m, \infty}$ (or $\mathcal{S}_{-\infty, L}$ ) of functions that are merely $m$-convex (or $L$ concave). Then $\mathcal{S}_{0, \infty}$ just is the set of convex functions and the following properties hold:

$$
\mathcal{S}_{m, \infty} \cap \mathcal{S}_{-\infty, L}=\mathcal{S}_{m, L} \subset \mathcal{S}_{\sigma, \mu} \text { if } \sigma \leq m \leq L \leq \mu
$$

Indeed, if $f \in \mathcal{S}_{m, L}$ and $\sigma \leq m$, then $f_{\sigma}$ equals $f_{m}+(m-$ $\sigma) q$ and is convex, i.e., $f \in \mathcal{S}_{\sigma, \infty}$. If $L \leq \mu$, concavity of $f^{\mu}$ (and thus $f \in \mathcal{S}_{-\infty, \mu}$ ) follows from $f^{\mu}=f^{L}+(\mu-L) q$.

The definition of the subdifferential $\partial f$ for a convex function $f \in \mathcal{S}_{0, \infty}$ can be seamlessly extended as follows. Definition 2. For $f \in \mathcal{S}_{m, \infty}$, the subdifferential of $f$ is defined with any $\sigma \in(-\infty, m]$ as

$$
\begin{equation*}
\partial f:=\partial f_{\sigma}+\sigma I . \tag{10}
\end{equation*}
$$

For $f \in \mathcal{S}_{-\infty, L}$, it is given for any $\mu \in[L, \infty)$ by

$$
\begin{equation*}
\partial f:=\mu I-\partial f^{\mu} \tag{11}
\end{equation*}
$$

On the right in (10) and (11), the usual subdifferential for convex functions appears. These definitions make sense since they are invariant under the choice of $\sigma, \mu$, respectively. For (10) and with $\sigma_{1}<\sigma_{2} \leq m$, this follows from

$$
\partial f_{\sigma_{1}}=\partial\left(f_{\sigma_{2}}+\left(\sigma_{2}-\sigma_{1}\right) q\right)=\partial f_{\sigma_{2}}+\left(\sigma_{2}-\sigma_{1}\right) I
$$

by using (9) and standard rules for the subdifferential of convex functions. For (11) and $L \leq \mu_{1}<\mu_{2}$, one relies on $\mu_{2} I-\partial f^{\mu_{2}}=\mu_{2} I-\partial\left(f^{\mu_{1}}+\left(\mu_{2}-\mu_{1}\right) q\right)=\mu_{1} I-\partial f^{\mu_{1}}$.
Lemma 3. For the extended subdifferential, (10) and (11) hold as equalities for all $\sigma \in \mathbb{R}$ and $\mu \in \mathbb{R}$, respectively. Moroever, any function $f \in \mathcal{S}_{m, L}$ with $-\infty<m \leq L<\infty$ is differentiable and $\partial f$ is equal to the gradient $\bar{\nabla} f$ of $f$.
Proof. Let $\sigma>m$. Then $f_{\sigma}-(m-\sigma) q=f_{m}$ is convex, implying $f_{\sigma} \in \mathcal{S}_{m-\sigma, \infty}$. By (10) applied to $f_{\sigma}$, we infer $\partial f_{\sigma}=\partial\left(f_{\sigma}-(m-\sigma) q\right)+(m-\sigma) I=\left(\partial f_{m}+m I\right)-$ $\sigma I=\partial f-\sigma I$. Hence $\partial f_{\sigma}+\sigma I=\partial f$, which is (10) for $\sigma>m$. The proof of (11) for $\mu<L$ proceeds analogously.
In case of $f \in \mathcal{S}_{m, L}$ and with the standard subdifferential, $f_{m}+f^{L}=(L-m) q$ implies $\partial f_{m}(x)+\partial f^{L}(x)=(L-m) x$ for $x \in \mathbb{R}^{d}$. Therefore, $\partial f_{m}(x)$ is a singleton for every $x \in \mathbb{R}^{d}$ and, thus, $f_{m}$ is differentiable. Then the same holds for $f=f_{m}+m q$, and standard calculus rules show $\nabla f=\nabla f_{\sigma}+\sigma I=\mu I-\nabla f^{\mu}$ for all $\sigma, \mu \in \mathbb{R}$.

The following alternative characterizations of vectors in the subdifferentials in terms of quadratic lower and upper bounding functions extend to any parameters $m, L \in \mathbb{R}$.
Lemma 4. Let $x \in \mathbb{R}^{d}$. If $f \in \mathcal{S}_{m, \infty}$, then $d \in \partial f(x)$ iff

$$
\begin{equation*}
f(x)+d^{T} h+m q(h) \leq f(x+h) \text { for all } h \in \mathbb{R}^{d} . \tag{12}
\end{equation*}
$$

If $f \in \mathcal{S}_{-\infty, L}$, then $d \in \partial f(x)$ iff
$f(x+h) \leq f(x)+d^{T} h+L q(h)$ for all $h \in \mathbb{R}^{d}$.
Proof. If $f \in \mathcal{S}_{-\infty, m}, f_{m}$ is convex and by definition of the standard subdifferential, $z \in \partial f_{m}(x)$ holds iff

$$
\begin{equation*}
f_{m}(x)+z^{T} h \leq f_{m}(x+h) \text { for all } h \in \mathbb{R}^{d} . \tag{14}
\end{equation*}
$$

Since $q(x+h)-q(x)=x^{T} h+q(h)$, this is equivalent to $f(x)+(z+m x)^{T} h+m q(h) \leq f(x+h)$ for all $h \in \mathbb{R}^{d}$. The first statement follows from $\partial f_{m}(x)+m x=\partial f(x)$.
For the second, note that $-f \in \mathcal{S}_{-L, 0} \subset \mathcal{S}_{-L, \infty}$. Hence, $d \in \partial f(x)$ iff $-d \in \partial(-f)(x)$ iff (as just proven)
$-f(x+h) \geq-f(x)+(-d)^{T} h+(-L) q(h)$ for all $h \in \mathbb{R}^{d}$ iff (13) is valid.

From now on we tacitly assume $-\infty<m<L<\infty$ and prove a key inequality for functions in the class $\mathcal{S}_{m, L}$.
Theorem 5. Let $f \in \mathcal{S}_{m, L}$. Then

$$
\begin{equation*}
V(u)-V(y) \leq S(u, y) \text { for all } u, y \in \mathbb{R}^{d} \tag{15}
\end{equation*}
$$

is satisfied with

$$
\begin{align*}
V(x) & :=(L-m) f_{m}(x)-q\left(\nabla f_{m}(x)\right),  \tag{16}\\
S(u, y) & :=\nabla f_{m}(u)^{\top}\left[\nabla f^{L}(u)-\nabla f^{L}(y)\right] . \tag{17}
\end{align*}
$$

Proof. Let $\alpha:=L-m>0$. With $u \in \mathbb{R}^{d}$ and $d:=\nabla f_{m}(u)$, define the convex function

$$
g(x):=f_{m}(x)-d^{\top} x \text { for } x \in \mathbb{R}^{n} .
$$

Then $g$ is $\alpha$-concave, since it differs from $f_{m}$ by an affine function and $\alpha q-f_{m}=(L-m) q-f_{m}=f^{L}$ is convex. Hence $g \in \mathcal{S}_{0, \alpha}$. For any $y \in \mathbb{R}^{d}$, Lemma 4 then implies

$$
\inf _{z \in \mathbb{R}^{d}} g(z) \leq g(y)+\nabla g(y)^{T} h+\alpha q(h) \text { for all } h \in \mathbb{R}^{d} .
$$

One the one hand, the minimum of the quadratic function in $h$ on the right is $g(y)-\frac{1}{2 \alpha}\|\nabla g(y)\|^{2}=g(y)-\frac{1}{\alpha} q(\nabla g(y))$. On the other hand, $\nabla g(u)=\nabla f_{m}(u)-d=0$ implies that the left-hand side equals $g(u)$. Hence

$$
\alpha g(u)-\alpha g(y) \leq-q(\nabla g(y))
$$

With $e:=\nabla f_{m}(y)$ and since $\nabla g(y)=e-d$, we infer
$\alpha f_{m}(u)-\alpha f_{m}(y)-\alpha d^{T}(u-y) \leq-q(e)-d^{T}(d-e)+q(d)$. This gives
$\left[\alpha f_{m}(u)-q(d)\right]-\left[\alpha f_{m}(y)-q(e)\right] \leq d^{T}[\alpha(u-y)-(d-e)]$. The left-hand side just reads $V(u)-V(y)$ by (16). The right-hand is $S(u, y)$ in (17), since $\alpha(u-y)-(d-e)=(L-$ $m)(u-y)+m(u-y)-(\nabla f(u)-\nabla f(y))=L(u-y)-$ $(\nabla f(u)-\nabla f(y))$. This proves (15) for (16)-(17).

We emphasize that (15) can be interpreted as a dissipation inequality as addressed in detail in Scherer (2022b) for the class $\mathcal{S}_{0, \infty}$. This is not pursued any further in this paper.

## 3. STATIC QUADRATIC CONSTRAINTS

For stability analysis, we now focus on $f \in \mathcal{S}_{m, L}$ with $\nabla f(0)=0$, the class of which is denoted by $\mathcal{S}_{m, L}^{0}$. Note that any $f \in \mathcal{S}_{m, L}^{0}$ satisfies $\nabla f_{m}(0)=0$ and $\nabla f^{L}(0)=0$.
If $h \in \mathbb{N}$, we further introduce the $h$-lift of $f$ as

$$
\begin{equation*}
\tilde{f}(x):=f\left(x_{1}\right)+\cdots+f\left(x_{h}\right) \text { for } x \in\left(\mathbb{R}^{d}\right)^{h} . \tag{18}
\end{equation*}
$$

Since $\nabla \widetilde{f}(x)=\operatorname{col}\left(\nabla f\left(x_{1}\right), \ldots, \nabla f\left(x_{h}\right)\right)$, we clearly have $\widetilde{f} \in \mathcal{S}_{m, L}^{0}$ and infer that $\nabla \widetilde{f}$ is diagonally repeated.

Similarly, if defining $\widetilde{V}, \widetilde{S}$ for $\widetilde{f}$ as in Theorem 5, we get

$$
\begin{equation*}
\widetilde{V}(u)-\widetilde{V}(y) \leq \widetilde{S}(u, y) \text { for all } u, y \in\left(\mathbb{R}^{d}\right)^{h} \tag{19}
\end{equation*}
$$

Note that $\widetilde{V}, \widetilde{f}_{m}$, and $\widetilde{f}^{L}$ turn out to be the $h$-lifts of $V$, $f_{m}$, and $f^{L}$, respectively.
If $P \in \mathbb{R}^{h \times h}$ is any permutation matrix and if using $y:=\left(P \otimes I_{d}\right) u$ in (19), we can hence conclude $\widetilde{V}(y)=\widetilde{V}(u)$ and $\nabla \widetilde{f}^{L}(y)=\left(P \otimes I_{d}\right) \nabla \widetilde{f}^{L}(u)$. Therefore, (19) implies $0 \leq \nabla \widetilde{f}_{m}(u)^{\top}\left[(I-P) \otimes I_{d}\right] \nabla \widetilde{f}^{L}(u)$ for all $u \in\left(\mathbb{R}^{d}\right)^{h}$.
The arguments in (Mancera and Safonov, 2005; Fetzer and Scherer, 2017a) then lead to the following result.
Corollary 6. Let $f \in \mathcal{S}_{m, L}^{0}$. If $M \in \mathbb{R}^{h \times h}$ is doubly hyperdominant, then

$$
\begin{equation*}
0 \leq \nabla \widetilde{f}_{m}(u)^{\top}\left(M \otimes I_{d}\right) \nabla \widetilde{f}^{L}(u) \text { for all } u \in\left(\mathbb{R}^{d}\right)^{h} \tag{20}
\end{equation*}
$$

## 4. IQCS WITH TERMINAL COST

On the basis of Corollary 6 we are now in the position to construct so-called dynamic IQCs with a nontrivial terminal cost for the uncertainty $\Delta_{\rho}^{f}$ in (8).
First, we construct the filter (3) driven by $\operatorname{col}(z, w)$. With $S_{m, L}:=\left(\begin{array}{cc}L & -1 \\ -m & 1\end{array}\right) \in \mathbb{R}^{2 \times 2}$, we apply a static transformation

$$
\begin{equation*}
\binom{u_{1}}{u_{2}}:=\binom{L z-w}{-m z+w}=\left(S_{m, L} \otimes I_{d}\right)\binom{z}{w} . \tag{21}
\end{equation*}
$$

This results in $u_{1}=\nabla f^{L}(z)$ and $u_{2}=\nabla f_{m}(z)$ in case of $w=\nabla f(z)$, which motivates (21). Then the response $v=\operatorname{col}\left(y_{1}, u_{1}, y_{2}, u_{2}\right)$ of (3) is defined by filtering $u_{1}, u_{2}$ as

$$
\begin{equation*}
\binom{y_{1}}{u_{1}}=\binom{\psi_{1} I_{d}}{I_{d}} u_{1} \quad \text { and } \quad\binom{y_{2}}{u_{2}}=\binom{\psi_{2} I_{d}}{I_{d}} u_{2} \tag{22}
\end{equation*}
$$

with the FIR transfer functions $\psi_{1}(\mathrm{z})=\lambda_{0}+\sum_{k=1}^{\nu_{1}} \lambda_{k} \frac{1}{\mathrm{z}^{k}}$, and $\psi_{2}(\mathrm{z})=\sum_{k=1}^{\nu_{2}} \lambda_{-k} \frac{1}{\mathrm{z}^{k}}$, respectively. The coefficients of these filters of lengths $\nu_{1}, \nu_{2} \in \mathbb{N}_{0}$ are collected as

$$
\lambda:=\left(\begin{array}{lll}
\lambda_{\nu_{1}} & \cdots & \lambda_{1}\left|\lambda_{0}\right| \lambda_{-1} \ldots
\end{array} \lambda_{-\nu_{2}}\right)=:\left(\begin{array}{lll}
\lambda^{1} & \lambda^{0} & \lambda^{2}
\end{array}\right) .
$$

To construct the resulting overall realization (3), let $J_{\nu} \in$ $\mathbb{R}^{\nu \times \nu}$ be the upper Jordan block with eigenvalue zero and $e_{1}, e_{\nu} \in \mathbb{R}^{\nu}$ the first, last standard unit vectors. Then it is easy to check that the matrices in (3) can be taken as

$$
\begin{gathered}
A_{\Psi}:=\left(\begin{array}{cc}
J_{\nu_{1}} & 0 \\
0 & J_{\nu_{2}}
\end{array}\right) \otimes I_{d}, B_{\Psi}:=\left[\left(\begin{array}{cc}
e_{\nu_{1}} & 0 \\
0 & e_{\nu_{2}}
\end{array}\right) S_{m, L}\right] \otimes I_{d} \\
C_{\Psi}^{\lambda}:=\left(\begin{array}{cc}
\lambda^{1} & 0 \\
0 & 0 \\
0 & \lambda^{2} \\
0 & 0
\end{array}\right) \otimes I_{d}, D_{\Psi}^{\lambda}:=\left[\left(\begin{array}{cc}
\lambda^{0} & 0 \\
1 & 0 \\
0 & 0 \\
0 & 1
\end{array}\right) S_{m, L}\right] \otimes I_{d} .
\end{gathered}
$$

We further introduce the Toeplitz matrix $T^{h}(\lambda) \in \mathbb{R}^{h \times h}$ with the first column $\operatorname{col}\left(\lambda_{0}, \ldots, \lambda_{\nu_{1}}, 0, \ldots\right)$ and the first row $\left(\lambda_{0} \lambda_{-1} \cdots \lambda_{-\nu_{2}} 0 \cdots\right)$. For $h=\nu_{1}+1+\nu_{2}$ and in the row and column partition $\left(\nu_{1}+1\right)+\nu_{2},\left(\nu_{2}+1\right)+\nu_{1}$, respectively, its sub-blocks are denoted as

$$
T^{\nu_{1}+1+\nu_{2}}(\lambda)=\left(\begin{array}{ll}
T_{12}(\lambda) & T_{11}(\lambda)  \tag{23}\\
T_{22}(\lambda) & T_{21}(\lambda)
\end{array}\right)
$$

Finally, we set $F_{\rho^{-1}}^{h}:=\operatorname{diag}\left(1, \rho^{-1}, \ldots, \rho^{-(h-1)}\right) \in \mathbb{R}^{h \times h}$.
Theorem 7. Let $f \in \mathcal{S}_{m, L}^{0}$ for $L>m$ and fix $\rho>0$. Then the response of the filter (3) driven by $w=\Delta_{\rho}^{f}(z)$ satisfies the integral quadratic constraint

$$
\begin{equation*}
\sum_{t=0}^{T-1} v_{t}^{T} P v_{t} \geq \xi_{T}^{T} Z(E) \xi_{T} \text { for all } T \in \mathbb{N} \tag{24}
\end{equation*}
$$

with the running and terminal cost matrices
$P:=\left(\begin{array}{cc}0 & \left(\begin{array}{ll}0 & 1 \\ 1 & 0\end{array}\right) \otimes I_{d} \\ \left(\begin{array}{ll}0 & 1 \\ 1 & 0\end{array}\right) \otimes I_{d} & 0\end{array}\right), Z(E):=\left(\begin{array}{cc}0 & E^{\top} \otimes I_{d} \\ E \otimes I_{d} & 0\end{array}\right)$,
if the constraints

$$
F_{\rho^{-1}}^{\nu_{1}+1+\nu_{2}}\left(\begin{array}{lc}
T_{12}(\lambda) & T_{11}(\lambda)  \tag{25}\\
T_{22}(\lambda) & T_{21}(\lambda)-E
\end{array}\right) F_{\rho^{-1}}^{\nu_{1}+1+\nu_{2}} \text { is d.h.d. }
$$

and

$$
\begin{equation*}
\sum_{k=-\nu_{2}}^{\nu_{1}} \lambda_{k} \rho^{k} \geq 0, \quad \sum_{k=-\nu_{2}}^{\nu_{1}} \lambda_{k} \rho^{-k} \geq 0 \tag{26}
\end{equation*}
$$

hold for $\lambda=\left(\lambda^{1}, \lambda^{0}, \lambda^{2}\right) \in \mathbb{R}^{\nu_{1}+1+\nu_{2}}$ and $E \in \mathbb{R}^{\nu_{2} \times \nu_{1}}$.
Proof. Let $w=\Delta_{\rho}^{f}(z)$ for $z \in l_{2 e}^{d}$ and consider the response $v$ of (3). Recall that $v=\operatorname{col}\left(y_{1}, u_{1}, y_{2}, u_{2}\right)$ with the signals defined by (21)-(22). We also partition the filter's state-trajectory as $\xi=\left(\xi_{1}, \xi_{2}\right)$ according to $A_{\Psi}$. With the truncation and lifting operation for signals as in the notation section, it is easy to check that

$$
\left(\begin{array}{c}
\left(\xi_{j}\right)_{h}  \tag{27}\\
y_{j}^{h} \\
u_{j}^{h}
\end{array}\right)=\left(\begin{array}{c}
B_{j}^{h} \otimes I_{d} \\
D_{j}^{h} \otimes I_{d} \\
I
\end{array}\right) u_{j}^{h}
$$

holds, where $B_{j}^{h}:=\left(J_{\nu_{j}}^{h-1} e_{\nu_{j}}, \ldots, J_{\nu_{j}} e_{\nu_{j}}, e_{\nu_{j}}\right), D_{1}^{h}:=$ $T^{h}\left(\lambda^{1}, \lambda^{0}, 0\right)$, and $D_{2}^{h}:=T^{h}\left(\lambda^{2}, 0,0\right)$ (and since $\xi_{0}=0$ ).

With the structure of $P$, the representation (27) shows

$$
\begin{gather*}
\frac{1}{2} \sum_{t=0}^{h-1} v_{t}^{\top} P v_{t}=\sum_{t=0}^{h-1}\binom{\left(y_{2}\right)_{t}}{\left(u_{2}\right)_{t}}^{\top}\left(\left(\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right) \otimes I_{d}\right)\binom{\left(y_{1}\right)_{t}}{\left(u_{1}\right)_{t}}= \\
=\sum_{t=0}^{h-1}\left(\left(y_{2}\right)_{t}^{\top}\left(u_{1}\right)_{t}+\left(u_{2}\right)_{t}^{\top}\left(y_{1}\right)_{t}\right)=\left(y_{2}^{h}\right)^{\top} u_{1}^{h}+\left(u_{2}^{h}\right)^{\top} y_{1}^{h}= \\
=\left(u_{2}^{h}\right)^{\top}\left[\left(D_{2}^{h} \otimes I_{d}\right)^{\top}+\left(D_{1}^{h} \otimes I_{d}\right)\right] u_{1}^{h}= \\
=\left(u_{2}^{h}\right)^{\top}\left[T^{h}(\lambda) \otimes I_{d}\right] u_{1}^{h}, \tag{28}
\end{gather*}
$$

where we exploited $\left(D_{2}^{h}\right)^{\top}+D_{1}^{h}=T^{h}(\lambda)$. Due to the structure of $Z(E)$, we infer

$$
\begin{align*}
& \frac{1}{2} \xi_{h}^{\top} Z(E) \xi_{h}=\left(\xi_{2}\right)_{h}^{\top}\left(E \otimes I_{d}\right)\left(\xi_{1}\right)_{h}= \\
& =\left(u_{2}^{h}\right)^{\top}\left(B_{2}^{h} \otimes I_{d}\right)^{\top}\left(E \otimes I_{d}\right)\left(B_{1}^{h} \otimes I_{d}\right) u_{1}^{h}= \\
& \quad=\left(u_{2}^{h}\right)^{\top}\left[\left(\left(B_{2}^{h}\right)^{\top} E B_{1}^{h}\right) \otimes I_{d}\right] u_{1}^{h} \tag{29}
\end{align*}
$$

We now exploit $w=\Delta_{\rho}^{f}(z)$ to conclude that (21) leads to $\left(u_{1}\right)_{t}=\rho^{-t} \nabla f^{L}\left(\rho^{t} z_{t}\right)$ and $\left(u_{2}\right)_{t}=\rho^{-t} \nabla f_{m}\left(\rho^{t} z_{t}\right)$. With $z_{\rho}^{h}:=\left(F_{\rho}^{h} \otimes I_{d}\right) z^{h}$, we then get

$$
u_{1}^{h}=\left(F_{\rho^{-1}}^{h} \otimes I_{d}\right) \nabla \widetilde{f}^{L}\left(z_{\rho}^{h}\right), u_{2}^{h}=\left(F_{\rho^{-1}}^{h} \otimes I_{d}\right) \nabla \widetilde{f}_{m}\left(z_{\rho}^{h}\right)
$$

If combining with (28)-(29), (24) is guaranteed in case that

$$
\nabla \widetilde{f}_{m}\left(z_{\rho}^{T}\right)^{\top}\left(M_{\rho^{-1}}^{T} \otimes I_{d}\right) \nabla \widetilde{f}^{L}\left(z_{\rho}^{T}\right) \geq 0 \text { for all } T \in \mathbb{N}
$$

where we use the abbreviation

$$
\begin{equation*}
M_{\rho^{-1}}^{h}:=F_{\rho^{-1}}^{h}\left[T^{h}(\lambda)-\left(B_{2}^{h}\right)^{\top} E B_{1}^{h}\right] F_{\rho^{-1}}^{h} . \tag{30}
\end{equation*}
$$

By Corollary 6, it suffices to show that (30) is a d.h.d. matrix in order to conclude the proof.

Let $h=h_{0}:=\nu_{1}+1+\nu_{2}$. By $B_{j}^{h_{0}}=\binom{0}{\nu_{j}}$, observe that

$$
T^{h_{0}}(\lambda)-\left(B_{2}^{h_{0}}\right)^{\top} E B_{1}^{h_{0}}=\left(\begin{array}{cc}
T_{12}(\lambda) & T_{11}(\lambda)  \tag{31}\\
T_{22}(\lambda) & T_{21}(\lambda)-E
\end{array}\right)
$$

Hence $M_{\rho^{-1}}^{h_{0}}$ just equals (25) and is, by assumption, d.h.d.
As a first consequence, (31) has non-positive off-diagonal entries, because the diagonal entries of $F_{\rho^{-1}}^{h_{0}}$ are positive. In particular, if recalling (23), we can conclude $\lambda_{k} \leq 0$ for $k=-\nu_{2}, \ldots,-1,1, \ldots, \nu_{1}$. With (26), we hence infer that

$$
\begin{equation*}
F_{\rho^{-1}}^{h} T^{h}(\lambda) F_{\rho^{-1}}^{h} \text { is d.h.d. for all } h \in \mathbb{N} . \tag{32}
\end{equation*}
$$

Now let $h<h_{0}$. Then $T^{h}(\lambda)-\left(B_{2}^{h}\right)^{\top} E B_{1}^{h}$ is the right lower $h \times h$ sub-matrix of $T^{h_{0}}(\lambda)-\left(B_{2}^{h_{0}}\right)^{\top} E B_{1}^{h_{0}}$. Moreover, $F_{\rho^{-1}}^{h}$ is the right-lower $h \times h$ sub-block of $\rho^{h_{0}-h} F_{\rho^{-1}}^{h_{0}}$. Since principal sub-matrices and positive multiples of d.h.d. matrices are d.h.d., we infer that $M_{\rho^{-1}}^{h}$ is a d.h.d. matrix.
Finally let $h>h_{0}$. With $\nu:=h-h_{0}$ and by inspection, we extract the structure

$$
T^{h}(\lambda)-\left(B_{2}^{h}\right)^{\top} E B_{1}^{h}=\left(\begin{array}{ccc}
T^{\nu}(\lambda) & \leq 0 & 0  \tag{33}\\
\leq 0 & T_{12}(\lambda) & T_{11}(\lambda) \\
0 & T_{21}(\lambda) & T_{22}(\lambda)-E
\end{array}\right)
$$

in the partition $\left(\nu+\left(\nu_{1}+1\right)+\nu_{2}\right) \times\left(\nu+\left(\nu_{2}+1\right)+\nu_{1}\right)$. In particular, all off-diagonal entries of (33) are nonpositive, which implies the same for $M_{\rho^{-1}}^{h}$. Since $E$ does not affect the first $\nu+\nu_{1}+1$ rows of (33), the first $\nu+\nu_{1}+1$ entries of the column vectors $M_{\rho^{-1}}^{h} e$ and $F_{\rho^{-1}}^{h} T^{h}(\lambda) F_{\rho^{-1}}^{h} e$ are identical. Due to (32), these are nonnegative. Moreover, by (31) and (33), each of the last $\nu_{2}$ entry of $M_{\rho^{-1}}^{h} e$ differs from the corresponding one of $M_{\rho^{-1}}^{h_{0}} e$ by a positive multiple, which shows that it is nonnegative. In total, we infer $M_{\rho^{-1}}^{h} e \geq 0$. Since analogous arguments lead to $e^{T} M_{\rho^{-1}}^{h} \geq 0$, we have proven that $M_{\rho^{-1}}^{h}$ is a d.h.d. matrix.

## 5. GUARANTEEING STABILITY AND PERFORMANCE

Now we showcase a typical result that can be formulated with Theorem 7 in order to guarantee robust exponential stability and performance for the trajectories of the feedback loop (1)-(2); from now on we assume $D=0$ which assures that this loop is well-posed.

To this end, we transform (1)-(2) into (6)-(7) by exponential signal weighting as discussed in Section 1. If the filter (3) is driven by the signals $\bar{z}$ and $\bar{w}$ in the loop, we obtain a trajectory of

$$
\begin{equation*}
\sigma \eta=\mathcal{A} \eta+\mathcal{B} \bar{w}, \quad v=\mathcal{C} \eta+\mathcal{D} \bar{w}, \quad \bar{z}=\mathcal{C}_{p} \eta+\mathcal{D}_{p} \bar{w} \tag{34}
\end{equation*}
$$

with $\eta=\operatorname{col}(\xi, \bar{x})$ and the series interconnection matrices

Recall the definition of the fixed matrix $P$ and the function $Z(E)$ of $E$ in Theorem 7 and introduce the abbreviation

$$
\mathcal{Z}(E):=\left(\begin{array}{cc}
Z(E) & 0 \\
0 & 0
\end{array}\right) \in \mathbb{R}^{\left(n_{\Psi}+n\right) \times\left(n_{\Psi}+n\right)}
$$

for a more compact formulation of the following result.
Theorem 8. For fixed $\alpha, \beta \geq 0$, let $\mathcal{X}=\mathcal{X}^{\top}, E$ and $\lambda$ satisfy (25), (26) and

$$
\left(\begin{array}{cc}
\mathcal{A}^{\top} \mathcal{X} \mathcal{A}-\mathcal{X} & \mathcal{A}^{\top} \mathcal{X} \mathcal{B} \\
\mathcal{B}^{\top} \mathcal{X} \mathcal{A} & \mathcal{B}^{\top} \mathcal{X} \mathcal{B}
\end{array}\right)+\left(\begin{array}{cc}
\mathcal{C}^{\lambda} & \mathcal{D}^{\lambda} \\
\mathcal{C}_{p} & 0
\end{array}\right)^{\top}\left(\begin{array}{cc}
P & 0 \\
0 & \alpha I
\end{array}\right)\left(\begin{array}{cc}
\mathcal{C}^{\lambda} & \mathcal{D}^{\lambda} \\
\mathcal{C}_{p} & 0
\end{array}\right) \prec 0
$$

$$
\begin{equation*}
\beta \mathcal{C}_{p}^{\top} \mathcal{C}_{p} \prec \mathcal{X}+\mathcal{Z}(E) \tag{36}
\end{equation*}
$$

Then, for any $f \in \mathcal{S}_{m, L}^{0}$ and all initial conditions $x_{0} \in \mathbb{R}^{n}$, the state trajectory of (1)-(2) decays exponentially with rate $\rho$ and the following performance condition is satisfied:

$$
\begin{equation*}
\sum_{t=0}^{T-1} \alpha\left\|\rho^{-t} z_{t}\right\|^{2}+\beta\left\|\rho^{-T} z_{T}\right\|^{2} \leq x_{0}^{\top} X x_{0} \quad \forall T \in \mathbb{N} \tag{37}
\end{equation*}
$$

Due to the structure of $P$, we stress that (25), (26) and (36) are indeed affine in all optimization variables, including $\lambda$.
Proof. Any trajectory of the loop (1)-(2) transforms it into one of $(6)-(7)$ with $\bar{w}=\Delta_{\rho}^{f}(\bar{z})$, which drives (3) to generate a trajectory of (34). By slightly perturbing the first LMI in (36) and using $v=\mathcal{C} \eta+\mathcal{D} \bar{w}$ as well as $\bar{z}=\mathcal{C}_{p} \eta$, right-multiplying $\operatorname{col}\left(\eta_{t}, \bar{w}_{t}\right)$ and left-multiplying the transpose and summation for $t=0, \ldots, T-1$ (which are routine dissipation arguments (Scherer and Weiland, 2011)), we get

$$
\eta_{T}^{\top} \mathcal{X} \eta_{T}-\eta_{0}^{\top} \mathcal{X} \eta_{0}+\sum_{t=0}^{T-1} v_{t}^{\top} P v_{t}+\sum_{t=0}^{T-1}\left(\alpha\left\|\bar{z}_{t}\right\|^{2}+\varepsilon\left\|\bar{x}_{t}\right\|^{2}\right) \leq 0
$$

for all $T \in \mathbb{N}$. Note that the perturbation with $\varepsilon$ is introduced to be able to show the exponential convergence of the state-trajectory, as seen below. We can then exploit (24) to bound the third term from below and infer, using $\eta_{0}=\operatorname{col}\left(0, x_{0}\right)$, that

$$
\begin{equation*}
\sum_{t=0}^{T-1}\left(\alpha\left\|\bar{z}_{t}\right\|^{2}+\varepsilon\left\|\bar{x}_{t}\right\|^{2}\right)+\eta_{T}^{\top}[\mathcal{X}+\mathcal{Z}(E)] \eta_{T} \leq x_{0}^{\top} X x_{0} \tag{38}
\end{equation*}
$$

for all $T \in \mathbb{N}$. If left- and right-multiplying the second LMI in (36) with $\eta_{T}^{\top}$ and $\eta_{T}$ and again using $\bar{z}_{T}=\mathcal{C}_{p} \eta_{T}$, (38) implies $\sum_{t=0}^{T-1}\left(\alpha\left\|\bar{z}_{t}\right\|^{2}+\varepsilon\left\|\bar{x}_{t}\right\|^{2}\right)+\beta\left\|\bar{z}_{T}\right\|^{2} \leq x_{0}^{\top} X x_{0}$ for all $T \in \mathbb{N}$. Since $\bar{z}_{t}=\rho^{-t} z_{t}$ and $\bar{x}_{t}=\rho^{-t} x_{t}$, this proves the exponential decay of $x$ with rate $\rho$ and (37).

## 6. AN ILLUSTRATIVE NUMERICAL EXAMPLE

Let us only partially illustrate the benefit of our main results for a scenario with $d=1$. Specifically, we reveal how to combine time-domain results using generalized sector conditions with Theorem 8 involving the constructed OZF multipliers from absolute stability theory in the frequencydomain. We are aware of such attempts undertaken in Fang et al. (2008), but the seamless integration into dissipativity theory is new.

For positive $l, L \in \mathbb{R}$ consider the deadzone nonlinearity

$$
\operatorname{dzn}_{l, L}(x)=\left\{\begin{array}{ccc}
0 & \text { for } & -l \leq x \leq l  \tag{39}\\
L(x-l) & \text { for } & l \leq x \\
L(x+l) & \text { for } & x \leq-l
\end{array}\right.
$$

which is the gradient of a function in $\mathcal{S}_{0, L}^{0}$. Therefore, it is possible to use our results for analyzing the stability/performance properties of (1) in feedback with (39).

Since this nonlinearity is more specific, additional IQCs can be incorporated to potentially improve such tests. A particularly often studied one is based on the socalled generalized sector condition, as introduced for the saturation function $\operatorname{sat}_{l, L}(x)=L x-\operatorname{dzn}_{l, L}(x)$; from the very broad range of references, we only mention the books by Hu et al. (2006); Tarbouriech et al. (2011) for comprehensive discussions. The key is the observation that

$$
\binom{z-y}{\operatorname{dzn}_{l, L}(z)}^{\top} P_{L}\binom{z-y}{\operatorname{dzn}_{l, L}(z)} \geq 0 \text { with } P_{L}:=\left(\begin{array}{cc}
0 & L  \tag{40}\\
L & -2
\end{array}\right)
$$

holds for all $z, y \in \mathbb{R}$ with $|y| \leq l$. Indeed, $\operatorname{dzn}_{l, L}(z)$ is a convex combination of $L(z-y)$ and 0 ; hence $\operatorname{dzn}_{l, L}(z)=$ $\delta(z-y)$ holds for some $\delta=\delta(y, z) \in[0, L]$; then (40) follows since $\operatorname{col}\left(z-y, \operatorname{dzn}_{l, L}(z)\right)^{\top} P_{L} \operatorname{col}\left(z-y, \operatorname{dzn}_{l, L}(z)\right)=$ $(z-y)^{2} \operatorname{col}(1, \delta)^{\top} P_{L} \operatorname{col}(1, \delta)=(z-y)^{2} 2 \delta(L-\delta) \geq 0$.
With the new output $y=H x$ for (1) and by guaranteeing the bound $\sup _{t \geq 0}\left|y_{t}\right| \leq l$, (40) leads to a valid IQC for the signals $z-y$ and $\operatorname{dzn}_{l, L}(z)$ along the loop trajectories. This can be conically incorporated into the first LMI in (36) to obtain the subsequent inequality (41), while the amplitude bound on $y$ is guaranteed by (43).
Corollary 9. For fixed $\alpha, \beta \geq 0$ and positive $l, L>0$, let $\mathcal{X}=\mathcal{X}^{\top}, E, \lambda, H$ and $\mu \geq 0$ satisfy the constraints (25), (26) together with

$$
\begin{align*}
& \left(\begin{array}{cc}
\mathcal{A}^{\top} \mathcal{X} \mathcal{A}-\mathcal{X} & \mathcal{A}^{\top} \mathcal{X} \mathcal{B} \\
\mathcal{B}^{\top} \mathcal{X} \mathcal{A} & \mathcal{B}^{\top} \mathcal{X} \mathcal{B}
\end{array}\right)+\left(\begin{array}{cc}
\mathcal{C}^{\lambda} & \mathcal{D}^{\lambda} \\
\mathcal{C}_{p} & 0
\end{array}\right)^{\top}\left(\begin{array}{cc}
P & 0 \\
0 & \alpha I
\end{array}\right)\left(\begin{array}{ll}
\mathcal{C}^{\lambda} & \mathcal{D}^{\lambda} \\
\mathcal{C}_{p} & 0
\end{array}\right)+ \\
& +\mu\left(\begin{array}{cc|c}
0 & C-H & 0 \\
0 & 0 & 1
\end{array}\right)^{\top} P_{L}\left(\begin{array}{cc|c}
0 & C-H & 0 \\
0 & 0 & 1
\end{array}\right) \prec 0,  \tag{41}\\
& \beta \mathcal{C}_{p}^{\top} \mathcal{C}_{p} \prec \mathcal{X}+\mathcal{Z}(E),  \tag{42}\\
& (0 H)^{\top}(0 H) \prec l^{2}(\mathcal{X}+\mathcal{Z}(E)) \text {. } \tag{43}
\end{align*}
$$

Then the same conclusions as in Theorem 8 can be drawn for the interconnection of (1) with the deadzone nonlinearity (39), if the system's initial condition satisfies

$$
\begin{equation*}
x_{0} \in \mathcal{E}_{X}:=\left\{\xi \in \mathbb{R}^{n} \mid \xi^{\top} X \xi \leq 1\right\} \tag{44}
\end{equation*}
$$

Proof. We follow the dissipativity proof of Theorem 8. Given any exponentially weighted trajectory of the loop, we first note that (43) implies

$$
\begin{equation*}
\left|H \bar{x}_{t}\right|^{2} \leq l^{2} \eta_{t}^{\top}(\mathcal{X}+\mathcal{Z}(E)) \eta_{t} \text { for all } t \in \mathbb{N}_{0} \tag{45}
\end{equation*}
$$

This permits to show $\left|H \bar{x}_{t}\right| \leq l$ for all $t \in \mathbb{N}_{0}$ by induction. Indeed, we have $\eta_{0}^{\top}(\mathcal{X}+\mathcal{Z}(\bar{E})) \eta_{0}=x_{0}^{\top} X x_{0} \leq 1$ and thus $\left|H \bar{x}_{0}\right| \leq l$. Then assume that $\left|H \bar{x}_{t}\right| \leq l$ for all $t \leq T-1$. For these times $t$, we get $\left|\rho^{t} H \bar{x}_{t}\right| \leq l($ since $\rho \leq 1)$ and we also recall $\bar{w}_{t}=\rho^{-t} \operatorname{dzn}_{l, L}\left(\rho^{t} \bar{z}_{t}\right)$. Then (40) implies

$$
\begin{align*}
& \binom{\eta_{t}}{\bar{w}_{t}}^{\top}\left(\begin{array}{cc|c}
0 & C-H & 0 \\
0 & 0 & 1
\end{array}\right)^{\top} P_{L}\left(\begin{array}{cc|c}
0 & C-H & 0 \\
0 & 0 & 1
\end{array}\right)\binom{\eta_{t}}{\bar{w}_{t}}= \\
& =\rho^{-2 t}\binom{\rho^{t} \bar{z}_{t}-\rho^{t} H \bar{x}_{t}}{\operatorname{dzn}_{l, L}\left(\rho^{t} \bar{z}_{t}\right)}^{\top} P_{L}\binom{\rho^{t} \bar{z}_{t}-\rho^{t} H \bar{x}_{t}}{\operatorname{dzn}_{l, L}\left(\rho^{t} \bar{z}_{t}\right)} \geq 0 \tag{46}
\end{align*}
$$

for all $t \leq T-1$. Therefore, the dissipation arguments in the proof of Theorem 8 and applied to (41) lead to (38). Since $x_{0}^{\top} X x_{0} \leq 1$, this shows $\eta_{T}^{\top}(\mathcal{X}+\mathcal{Z}(E)) \eta_{T} \leq 1$ and thus $\left|H \bar{x}_{T}\right| \leq l$ by (45), which finishes the induction step.
We can now draw the conclusion that (46) is valid for all $t \in \mathbb{N}_{0}$. Despite the new term in the LMI (41) if compared

Fig. 1. Sizes of ellipsoids $\mathcal{E}_{X_{*}}$ for the generalized sector condition without (blue) and in combination with (red) O'Shea-Zames-Falb multipliers.
to the first one in (36), exactly the same dissipation arguments conclude the proof as for Theorem 8.
For reasons of space, we only exhibit one simple numerical experiment if (1) is defined with

$$
A=\left(\begin{array}{rr}
0.8 & 0.5 \\
-0.4 & 1.2
\end{array}\right), \quad B=\binom{-0.18}{1}, \quad C=(0.3-1.8)
$$

and $D=0$, interconnected with $w=\operatorname{sat}_{0.1, L}(z)$ for $L \in[0,1.3]$. We choose $\rho=1, \alpha=0, \beta=1$ and note that $1 / \sqrt{\operatorname{trace}(X)}$ can be considered as a measure for the size of the ellipsoid (44). This motivates to compute the infimal $\gamma_{*}$ (with an approximately optimal $X_{*} \succ 0$ ) such that the constraints in Corollary 9 in addition to trace $(X) \prec \gamma^{2} I$ hold (by using a line-search over $\mu$ and the LMI-solver of MATLAB (2020) with Yalmip (Lofberg, 2004).)
For all $x_{0} \in \mathcal{E}_{X_{*}}$, Corollary 9 then guarantees the bound $\sup _{t \geq 0}\left\|z_{t}\right\| \leq 1$. The sizes $1 / \gamma_{*}$ of $\mathcal{E}_{X_{*}}$ for the generalized sector condition from (Hu et al., 2006; Tarbouriech et al., 2011) depending on $L$ are depicted in blue in Fig. 1. The inclusion of dynamic multipliers of length $\nu=\widetilde{\nu}=1$ leads to an increase of the size of the ellipsoid (i.e. a reduction of conservatism) as shown by the red curve in Fig. 1.

## 7. CONCLUSIONS

We have given new time-domain IQCs with a terminal cost for exponentially weighted slope-restricted nonlinearities. For linear saturated systems, it has been demonstrated how these results permit to reduce conservatism by seamlessly merging local time-domain and frequency-domain techniques. The impact on the analysis of optimization algorithms or the safety verification of linear systems interconnected with neural networks is left for future work.
