# Strong tractability for multivariate integration in a subspace of the Wiener algebra* 

Takashi Goda ${ }^{\dagger}$

June 5, 2023

#### Abstract

Building upon recent work by the author, we prove that multivariate integration in the following subspace of the Wiener algebra over $[0,1)^{d}$ is strongly polynomially tractable: $F_{d}:=\left\{f \in C\left([0,1)^{d}\right)\left|\|f\|:=\sum_{\boldsymbol{k} \in \mathbb{Z}^{d}}\right| \hat{f}(\boldsymbol{k}) \mid \max \left(\operatorname{width}(\operatorname{supp}(\boldsymbol{k})), \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right)<\infty\right\}$, with $\hat{f}(\boldsymbol{k})$ being the $\boldsymbol{k}$-th Fourier coefficient of $f, \operatorname{supp}(\boldsymbol{k}):=\left\{j \in\{1, \ldots, d\} \mid k_{j} \neq 0\right\}$, and width : $2^{\{1, \ldots, d\}} \rightarrow\{1, \ldots, d\}$ being defined by $$
\operatorname{width}(u):=\max _{j \in u} j-\min _{j \in u} j+1,
$$ for non-empty subset $u \subseteq\{1, \ldots, d\}$ and $\operatorname{width}(\emptyset):=1$. Strong polynomial tractability is achieved by an explicit quasi-Monte Carlo rule using a multiset union of Korobov's $p$-sets. We also show that, if we replace $\operatorname{width}(\operatorname{supp}(\boldsymbol{k}))$ with 1 for all $\boldsymbol{k} \in \mathbb{Z}^{d}$ in the above definition of norm, multivariate integration is polynomially tractable but not strongly polynomially tractable.

## 1 Introduction and main results

This paper concerns numerical integration for multivariate functions defined over the $d$-dimensional unit cube. For a Riemann integrable function $f:[0,1)^{d} \rightarrow \mathbb{R}$, we approximate its integral

$$
I_{d}(f)=\int_{[0,1)^{d}} f(\boldsymbol{x}) \mathrm{d} \boldsymbol{x}
$$

by

$$
Q_{d, n}(f)=\sum_{h=0}^{n-1} w_{h} f\left(\boldsymbol{x}_{h}\right)
$$

[^0]with sets of $n$ sampling points $\left\{\boldsymbol{x}_{0}, \ldots, \boldsymbol{x}_{n-1}\right\} \subset[0,1)^{d}$ and associated weights $\left\{w_{0}, \ldots, w_{n-1}\right\}$. QuasiMonte Carlo (QMC) rule denotes a special case of $Q_{d, n}$ where all the weights $w_{h}$ are equal to $1 / n$. The worst-case error of an algorithm $Q_{d, N}$ in a Banach space $F$ with norm $\|\cdot\|$ is defined by
$$
e^{\mathrm{wor}}\left(F, Q_{d, n}\right):=\sup _{f \in F,\|f\| \leq 1}\left|I_{d}(f)-Q_{d, n}(f)\right|
$$

In the field of information-based complexity 11, 12, 16, we are interested in how the information complexity $n(\varepsilon, d, F)$ grows in the reciprocal of the error tolerance $\varepsilon \in(0,1)$ and the dimension $d$. Here, the information complexity is defined as the minimum number of function values, among all possible $Q_{d, n}$, needed to make the worst-case error in $F$ no greater than $\varepsilon$, that is,

$$
n(\varepsilon, d, F):=\min \left\{n \in \mathbb{N} \mid \exists Q_{d, n}: e^{\mathrm{wor}}\left(F, Q_{d, n}\right) \leq \varepsilon\right\}
$$

In a recent work by the author [6], it has been proven that the information complexity for the following unweighted subspace of the Wiener algebra grows only polynomially both in $\varepsilon^{-1}$ and $d$ :

$$
F_{d}^{1}:=\left\{f \in C\left([0,1)^{d}\right)\left|\|f\|:=\sum_{\boldsymbol{k} \in \mathbb{Z}^{d}}\right| \hat{f}(\boldsymbol{k}) \mid \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right)<\infty\right\},
$$

with $\hat{f}(\boldsymbol{k})$ being the $\boldsymbol{k}$-th Fourier coefficient of $f$, i.e.,

$$
\hat{f}(\boldsymbol{k})=\int_{[0,1)^{d}} f(\boldsymbol{x}) \exp (-2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}) \mathrm{d} \boldsymbol{x}
$$

and $\operatorname{supp}(\boldsymbol{k}):=\left\{j \in\{1, \ldots, d\} \mid k_{j} \neq 0\right\}$. More precisely, it has been shown that an upper bound $n\left(\varepsilon, d, F_{d}^{1}\right) \leq C_{1} \varepsilon^{-3} d^{3}$ holds for a positive constant $C_{1}$, concluding that the problem of multivariate integration in $F_{d}^{1}$ is polynomially tractable. We refer to [9, 10 for more recent progress on this line of research. In this context, an unweighted function space $F$ refers to a space where all variables and groups of variables play an equal role. Therefore, for any permutation matrix $\pi$ and $f \in F$, it holds that $f \circ \pi \in F$ and $\|f \circ \pi\|=\|f\|$. The result presented in [6] builds upon the work of Dick [1], who established polynomial tractability for multivariate integration in the intersection of the Wiener algebra and an unweighted space of Hölder continuous functions.

As a continuation of [6], we prove the following result in this paper:
Theorem 1. Let $F_{d}^{2}$ be a subspace of the Wiener algebra defined by

$$
F_{d}^{2}:=\left\{f \in C\left([0,1)^{d}\right)\left|\|f\|:=\sum_{\boldsymbol{k} \in \mathbb{Z}^{d}}\right| \hat{f}(\boldsymbol{k}) \mid \max \left(\operatorname{width}(\operatorname{supp}(\boldsymbol{k})), \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right)<\infty\right\}
$$

where width : $2^{\{1, \ldots, d\}} \rightarrow\{1, \ldots, d\}$ is defined by

$$
\operatorname{width}(u):=\max _{j \in u} j-\min _{j \in u} j+1,
$$

for non-empty subset $u \subseteq\{1, \ldots, d\}$, and $\operatorname{width}(\emptyset)=1$. Then, there exists a positive constant $C_{2}$ such that, for any $d \in \mathbb{N}$ and $\varepsilon \in(0,1)$, we have

$$
n\left(\varepsilon, d, F_{d}^{2}\right) \leq C_{2} \varepsilon^{-3} /\left(\log \varepsilon^{-1}\right)
$$

In comparison to the result of [6] for $F_{d}^{1}$, by replacing 1 (the first argument in taking the maximum for each $\boldsymbol{k}$ ) with width $(\operatorname{supp}(\boldsymbol{k}))$ in the definition of norms, the polynomial dependence of the information complexity on the dimension $d$ does not show up anymore, meaning that the problem of multivariate integration in $F_{d}^{2}$ is strongly polynomially tractable. This result is strengthened by the following theorem on the former space $F_{d}^{1}$.

Theorem 2. For any linear algorithm $Q_{d, n}$ using n function values, we have $e^{\mathrm{wor}}\left(F_{d}^{1}, Q_{d, n}\right) \geq d /\left(2 n^{2}\right)$ for any $d \in \mathbb{N}$ and $n>2 d$.

Note that there is a significant gap between the lower bound on the worst-case error obtained above and the upper bound of order $d n^{-1 / 3}$ shown in [6]. Nevertheless, this result implies that a dependence of the information complexity on the dimension $d$ cannot be eliminated for $F_{d}^{1}$. Therefore, the problem of multivariate integration in $F_{d}^{1}$ is polynomially tractable but not strongly polynomially tractable. As a future research direction, it would be interesting to study whether an intermediate space between $F_{d}^{1}$ and $F_{d}^{2}$ still exhibits strong polynomial tractability for multivariate integration. As we have $1 \leq|\operatorname{supp}(\boldsymbol{k})| \leq \operatorname{width}(\operatorname{supp}(\boldsymbol{k}))$ for all $\boldsymbol{k} \in \mathbb{Z}^{d}$ when defining $|\operatorname{supp}(\mathbf{0})|=1$, one of the most natural spaces we can consider is an unweighted space

$$
F_{d}^{3}:=\left\{f \in C\left([0,1)^{d}\right)\left|\|f\|:=\sum_{\boldsymbol{k} \in \mathbb{Z}^{d}}\right| \hat{f}(\boldsymbol{k}) \mid \max \left(|\operatorname{supp}(\boldsymbol{k})|, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right)<\infty\right\}
$$

Note that, although the space $F_{d}^{2}$ is weighted, it remains invariant under the reversion of the variables, i.e., if $f \in F_{d}^{2}$, then we have $g \in F_{d}^{2}$ and $\|f\|=\|g\|$ where $g\left(x_{1}, \ldots, x_{d}\right)=f\left(x_{d}, \ldots, x_{1}\right)$. This is in contrast to many existing results on strong polynomial tractability for multivariate integration in the worst-case setting, where weight parameters are introduced to model the relative importance of each group of variables, and variables are typically assumed ordered in decreasing importance order. See [2, 5, 11, 12, 15] among many others. In fact, it seems not possible to characterize the space $F_{d}^{2}$ in such a way. The author believes that further tractability studies in subspaces of the Wiener algebra will offer new insights into the field of information-based complexity, particularly regarding (strong) polynomial tractability in (un)weighted spaces.

## 2 Proof of Theorem 1

This section is devoted to proving Theoremby providing an explicit QMC rule that attains the desired worst-case error bound. The QMC rule considered here is exactly the same as the one discussed in [6]. For an integer $m \geq 2$, let

$$
\mathbb{P}_{m}:=\{\lceil m / 2\rceil<p \leq m \mid p \text { is prime }\} .
$$

It is known that there exist constants $c_{\mathbb{P}}$ and $C_{\mathbb{P}}$ with $0<c_{\mathbb{P}}<\min \left(1, C_{\mathbb{P}}\right)$ such that

$$
\begin{equation*}
c_{\mathbb{P}} \frac{m}{\log m} \leq\left|\mathbb{P}_{m}\right| \leq C_{\mathbb{P}} \frac{m}{\log m}, \tag{1}
\end{equation*}
$$

for all $m \geq 2$, see [13, Corollaries 1-3]. Now, given an integer $m \geq 2$, we define two different point sets as multiset unions:

$$
P_{d, m}^{1}=\bigcup_{p \in \mathbb{P}_{m}} S_{d, p} \quad \text { and } \quad P_{d, m}^{2}=\bigcup_{p \in \mathbb{P}_{m}} T_{d, p}
$$

where $S_{d, p}=\left\{\boldsymbol{x}_{h}^{(p)} \mid 0 \leq h<p^{2}\right\}$ and $T_{d, p}=\left\{\boldsymbol{x}_{h, \ell}^{(p)} \mid 0 \leq h, \ell<p\right\}$ are sets with $p^{2}$ points known as Korobov's p-sets [1, 5, 7, 8]. These point sets are defined as follows:

$$
\boldsymbol{x}_{h}^{(p)}=\left(\left\{\frac{h}{p^{2}}\right\},\left\{\frac{h^{2}}{p^{2}}\right\}, \ldots,\left\{\frac{h^{d}}{p^{2}}\right\}\right)
$$

and

$$
\boldsymbol{x}_{h, \ell}^{(p)}=\left(\left\{\frac{h \ell}{p}\right\},\left\{\frac{h \ell^{2}}{p}\right\}, \ldots,\left\{\frac{h \ell^{d}}{p}\right\}\right)
$$

respectively, where we write $\{x\}=x-\lfloor x\rfloor$ to denote the fractional part of a non-negative real number $x$. It is important to note that taking the multiset unions of Korobov's $p$-sets with different primes $p$ is crucial in our error analysis. Trivially we have

$$
\left|P_{d, m}^{1}\right|=\left|P_{d, m}^{2}\right|=\sum_{p \in \mathbb{P}_{m}} p^{2}
$$

The following result on the exponential sums refines the known results from [7, Lemmas 4.5 \& 4.6] as well as [5] Lemmas 4.4 \& 4.5].
Lemma 3. Let $d \in \mathbb{N}$ and $p$ be a prime with $p \geq d$. For any $\boldsymbol{k} \in \mathbb{Z}^{d} \backslash\{\mathbf{0}\}$ such that there exists at least one index $j^{*} \in\{1, \ldots, d\}$ where $k_{j^{*}}$ is not divisible by $p$, i.e., $p \nmid \boldsymbol{k}$, the following bounds hold:

$$
\left|\frac{1}{p^{2}} \sum_{h=0}^{p^{2}-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right| \leq \frac{\operatorname{width}(\operatorname{supp}(\boldsymbol{k}))}{p}
$$

and

$$
\left|\frac{1}{p^{2}} \sum_{h, \ell=0}^{p-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h, \ell}^{(p)}\right)\right| \leq \frac{\operatorname{width}(\operatorname{supp}(\boldsymbol{k}))}{p}
$$

Proof. Let us consider the first bound. As we have $\left\{0, \ldots, p^{2}-1\right\}=\left\{h_{0}+h_{1} p \mid 0 \leq h_{0}, h_{1}<p\right\}$ and, for each pair of $h_{0}, h_{1} \in\{0, \ldots, p-1\}$, it holds that

$$
\begin{aligned}
\exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h_{0}+h_{1} p}^{(p)}\right) & =\exp \left(\frac{2 \pi i}{p^{2}} \sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j}\left(h_{0}+h_{1} p\right)^{j}\right) \\
& =\exp \left(\frac{2 \pi i}{p^{2}} \sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j} \sum_{a=0}^{j}\binom{j}{a} h_{0}^{a}\left(h_{1} p\right)^{j-a}\right) \\
& =\exp \left(\frac{2 \pi i}{p^{2}} \sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j}\left(h_{0}^{j}+j h_{0}^{j-1} h_{1} p\right)\right)
\end{aligned}
$$

we obtain

$$
\begin{aligned}
\left|\frac{1}{p^{2}} \sum_{h=0}^{p^{2}-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right|= & \left|\frac{1}{p^{2}} \sum_{h_{0}, h_{1}=0}^{p-1} \exp \left(\frac{2 \pi i}{p^{2}} \sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j}\left(h_{0}^{j}+j h_{0}^{j-1} h_{1} p\right)\right)\right| \\
= & \left|\frac{1}{p} \sum_{h_{0}=0}^{p-1} \exp \left(\frac{2 \pi i}{p^{2}} \sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j} h_{0}^{j}\right) \frac{1}{p} \sum_{h_{1}=0}^{p-1} \exp \left(\frac{2 \pi i h_{1}}{p} \sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j} j h_{0}^{j-1}\right)\right| \\
\leq & \frac{1}{p} \sum_{h_{0}=0}^{p-1}\left|\frac{1}{p} \sum_{h_{1}=0}^{p-1} \exp \left(\frac{2 \pi i h_{1}}{p} \sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j} j h_{0}^{j-1}\right)\right| \\
= & \frac{1}{p} \sum_{h_{0}=0}^{p-1} 1, \\
& \sum_{j \in \operatorname{supp}(\boldsymbol{k})}^{k_{j} j h_{0}^{j-1} \equiv 0}(\bmod p)
\end{aligned}
$$

where the last equality follows from the well-known character property for the trigonometric functions [3. Lemma 4.3]. Here, by denoting $j_{\min }=\min _{j \in \operatorname{supp}(\boldsymbol{k})} j$ and $j_{\max }=\max _{j \in \operatorname{supp}(\boldsymbol{k})} j$, we have

$$
\sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j} j h_{0}^{j-1}=\sum_{\substack{j=j_{\min } \\ j \in \operatorname{supp}(\boldsymbol{k})}}^{j_{\max }} k_{j} j h_{0}^{j-1}=h_{0}^{j_{\min }-1} \sum_{\substack{j=j_{\min } \\ j \in \operatorname{supp}(\boldsymbol{k})}}^{j_{\max }} k_{j} j h_{0}^{j-j_{\min }} .
$$

As the last sum over $j$ is a polynomial in $h_{0}$ with degree $j_{\max }-j_{\min }$, the number of solutions of the congruence $\sum_{j \in \operatorname{supp}(\boldsymbol{k})} k_{j} j h_{0}^{j-1} \equiv 0(\bmod p)$ is at most $j_{\max }-j_{\min }+1=\operatorname{width}(\operatorname{supp}(\boldsymbol{k}))$. Thus the result follows. Since the second bound can be proven in the same manner, we omit the details.

Note that, if $k_{j}$ is divisible by $p$ for all $j$, i.e., $p \mid \boldsymbol{k}$, then we only have a trivial bound on the exponential sum, which is 1 . Using this refined result, we obtain the following bounds on the exponential sums for our point sets $P_{d, m}^{1}$ and $P_{d, m}^{2}$.

Corollary 4. Let $d \in \mathbb{N}$ and $m \geq 2$ with $\min _{p \in \mathbb{P}_{m}} p \geq d$. For any $\boldsymbol{k} \in \mathbb{Z}^{d} \backslash\{\mathbf{0}\}$, it holds that

$$
\left|\frac{1}{\left|P_{d, m}^{1}\right|} \sum_{p \in \mathbb{P}_{m}} \sum_{h=0}^{p^{2}-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right| \leq \frac{1}{m}\left(4 \operatorname{width}(\operatorname{supp}(\boldsymbol{k}))+\frac{8}{c_{\mathbb{P}}} \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right),
$$

and

$$
\left|\frac{1}{\left|P_{d, m}^{2}\right|} \sum_{p \in \mathbb{P}_{m}} \sum_{h, \ell=0}^{p-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h, \ell}^{(p)}\right)\right| \leq \frac{1}{m}\left(4 \operatorname{width}(\operatorname{supp}(\boldsymbol{k}))+\frac{8}{c_{\mathbb{P}}} \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right) .
$$

Proof. The following proof for the first bound is similar to that of [6, Corollary 2.3], and the second bound can be proven in a similar way, so we omit the details. Using Lemma 3 we have

$$
\begin{aligned}
&\left|\frac{1}{\left|P_{d, m}^{1}\right|} \sum_{p \in \mathbb{P}_{m}} \sum_{h=0}^{p^{2}-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right| \leq \frac{1}{\left|P_{d, m}^{1}\right|} \sum_{p \in \mathbb{P}_{m}}\left|\sum_{h=0}^{p^{2}-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right| \\
& \leq \frac{1}{\left|P_{d, m}^{1}\right|} \sum_{\substack{p \in \mathbb{P}_{m} \\
p \nmid k}} p \operatorname{width}(\operatorname{supp}(\boldsymbol{k}))+\frac{1}{\left|P_{d, m}^{1}\right|} \sum_{\substack{p \in \mathbb{P}_{m} \\
p \mid \boldsymbol{k}}} p^{2} \\
& \leq \frac{m\left|\mathbb{P}_{m}\right|}{\left|P_{d, m}^{1}\right|} \operatorname{width}(\operatorname{supp}(\boldsymbol{k}))+\frac{m^{2}}{\left|P_{d, m}^{1}\right|} \sum_{\substack{p \in \mathbb{P}_{m} \\
p \mid \boldsymbol{k}}} 1 \\
& \leq \frac{m\left|\mathbb{P}_{m}\right|}{(m / 2)^{2}\left|\mathbb{P}_{m}\right|} \operatorname{width}(\operatorname{supp}(\boldsymbol{k}))+\frac{m^{2}}{(m / 2)^{2}\left|\mathbb{P}_{m}\right|} \sum_{p \in \mathbb{P}_{m}} 1 \\
& p \mid \boldsymbol{k} \\
& \leq \frac{4}{m}{\operatorname{width}(\operatorname{supp}(\boldsymbol{k}))+\frac{4 \log m}{c_{\mathbb{P}} m} \sum_{\substack{p \in \mathbb{P}_{m} \\
p \mid \boldsymbol{k}}} 1,}
\end{aligned}
$$

where the last inequality follows from (1). To give a bound on the last sum over $p \in \mathbb{P}_{m}$ which divides $\boldsymbol{k}$, we use the fact that, for any integers $k, n \in \mathbb{N}, k$ has at most $\log _{n} k$ prime divisors larger than or equal to $n$. With $\mathbb{I}(\cdot)$ denoting the indicator function, for any index $j^{*} \in \operatorname{supp}(\boldsymbol{k})$, we get

$$
\sum_{\substack{p \in \mathbb{P}_{m} \\ p \mid \boldsymbol{k}}} 1=\sum_{p \in \mathbb{P}_{m}} \prod_{j \in \operatorname{supp}(\boldsymbol{k})} \mathbb{I}\left(p \mid k_{j}\right) \leq \sum_{p \in \mathbb{P}_{m}} \mathbb{I}\left(p \mid k_{j^{*}}\right) \leq \log _{\lceil m / 2\rceil+1}\left|k_{j^{*}}\right| \leq \frac{2 \log \left|k_{j^{*}}\right|}{\log m}
$$

Since this inequality applies to any index $j^{*} \in \operatorname{supp}(\boldsymbol{k})$, it holds that

$$
\sum_{\substack{p \in \mathbb{P}_{m} \\ p \mid \boldsymbol{k}}} 1 \leq \frac{2}{\log m} \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right| .
$$

This completes the proof.
Now we are ready to prove Theorem 1 .

Proof of Theorem 1. Since any function $f \in F_{d}^{2}$ has an absolutely convergent Fourier series, by letting $Q_{d, n}$ being the QMC rule using $P_{d, m}^{1}\left(\right.$ or $\left.P_{d, m}^{2}\right)$ for some $m \geq 2$ with $\min _{p \in \mathbb{P}_{m}} p \geq d$, it follows from Corollary 4 that, with $n$ equal to $\sum_{p \in \mathbb{P}_{m}} p^{2}$,

$$
\begin{aligned}
\left|I_{d}(f)-Q_{d, n}(f)\right| & =\left|I_{d}(f)-\frac{1}{\left|P_{d, m}^{1}\right|} \sum_{p \in \mathbb{P}_{m}} \sum_{h=0}^{p^{2}-1} f\left(\boldsymbol{x}_{h}^{(p)}\right)\right| \\
& =\left|\hat{f}(\mathbf{0})-\frac{1}{\left|P_{d, m}^{1}\right|} \sum_{p \in \mathbb{P}_{m}} \sum_{h=0}^{p^{2}-1} \sum_{\boldsymbol{k} \in \mathbb{Z}^{d}} \hat{f}(\boldsymbol{k}) \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right| \\
& =\left|\sum_{\boldsymbol{k} \in \mathbb{Z}^{d} \backslash\{\mathbf{0}\}} \hat{f}(\boldsymbol{k}) \frac{1}{\left|P_{d, m}^{1}\right|} \sum_{p \in \mathbb{P}_{m}} \sum_{h=0}^{p^{2}-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right| \\
& \leq \sum_{\boldsymbol{k} \in \mathbb{Z}^{d} \backslash\{\mathbf{0}\}}|\hat{f}(\boldsymbol{k})|\left|\frac{1}{\left|P_{d, m}^{1}\right|} \sum_{p \in \mathbb{P}_{m}} \sum_{h=0}^{p^{2}-1} \exp \left(2 \pi i \boldsymbol{k} \cdot \boldsymbol{x}_{h}^{(p)}\right)\right| \\
& \leq \frac{1}{m} \sum_{\boldsymbol{k} \in \mathbb{Z}^{d} \backslash\{\mathbf{0}\}}|\hat{f}(\boldsymbol{k})|\left(4 \operatorname{width}(\operatorname{supp}(\boldsymbol{k}))+\frac{8}{c_{\mathbb{P}}} \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right) \\
& \leq \frac{16}{c_{\mathbb{P}} m} \sum_{\boldsymbol{k} \in \mathbb{Z}^{d} \backslash\{\mathbf{0}\}}|\hat{f}(\boldsymbol{k})| \max \left(\operatorname{width}(\operatorname{supp}(\boldsymbol{k})), \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}\right|\right) \leq \frac{16}{c_{\mathbb{P}} m}\|f\| .
\end{aligned}
$$

This leads to an upper bound on the worst-case error as

$$
e^{\mathrm{wor}}\left(F_{d}^{2}, Q_{d, n}\right) \leq \frac{16}{c_{\mathbb{P}} m}
$$

Therefore, in order to make $e^{\text {wor }}\left(F_{d}^{2}, Q_{d, n}\right)$ less than or equal to $\varepsilon \in(0,1)$, it suffices to choose $m=\left\lceil 16 c_{\mathbb{P}}^{-1} \varepsilon^{-1}\right\rceil$ and we have

$$
n\left(\varepsilon, d, F_{d}^{2}\right) \leq \sum_{p \in \mathbb{P}_{\left\lceil 16 c_{\mathbb{P}}^{-1} \varepsilon^{-1}\right\rceil}} p^{2} \leq C_{\mathbb{P}} \frac{\left\lceil 16 c_{\mathbb{P}}^{-1} \varepsilon^{-1}\right\rceil}{\log \left\lceil 16 c_{\mathbb{P}}^{-1} \varepsilon^{-1}\right\rceil} \times\left(\left\lceil 16 c_{\mathbb{P}}^{-1} \varepsilon^{-1}\right\rceil\right)^{2}
$$

from which the result follows immediately.

## 3 Proof of Theorem 2

Proof of Theorem [2. We adopt a similar approach as in the proofs of [14, Theorem 1] and [4, Theorem 1]. Consider an arbitrary linear algorithm $Q_{d, n}(f)=\sum_{h=0}^{n-1} w_{h} f\left(\boldsymbol{x}_{h}\right)$. For a set $\mathcal{A} \subset \mathbb{Z}^{d}$ with enough cardinality $|\mathcal{A}|>n$, we define a function $g:[0,1)^{d} \rightarrow \mathbb{C}$ by

$$
g(\boldsymbol{x})=\sum_{\boldsymbol{k} \in \mathcal{A}} c_{\boldsymbol{k}} \exp (2 \pi i \boldsymbol{k} \cdot \boldsymbol{x})
$$

with $c_{\boldsymbol{k}} \in \mathbb{C}$, which satisfies $g\left(\boldsymbol{x}_{h}\right)=0$ for all $h=0, \ldots, n-1$. In fact, there exists a non-zero vector of $\left(c_{\boldsymbol{k}}\right)_{\boldsymbol{k} \in \mathcal{A}}$, as the condition that $g\left(\boldsymbol{x}_{h}\right)=0$ for all $h=0, \ldots, n-1$ forms $n$ homogeneous linear equations with $|\mathcal{A}|>n$ unknowns $c_{\boldsymbol{k}}$. Let us normalize these coefficients in such a way that

$$
\max _{\boldsymbol{k} \in \mathcal{A}}\left|c_{\boldsymbol{k}}\right|=c_{\boldsymbol{\ell}}=1 \quad \text { for some } \boldsymbol{\ell} \in \mathcal{A} .
$$

With this $\boldsymbol{\ell}$ and a positive constant $C$, we define another function $\tilde{g}:[0,1)^{d} \rightarrow \mathbb{C}$ as follows:

$$
\tilde{g}(\boldsymbol{x})=C \exp (-2 \pi i \boldsymbol{\ell} \cdot \boldsymbol{x}) g(\boldsymbol{x})=C \sum_{\boldsymbol{k} \in \mathcal{A}} c_{\boldsymbol{k}} \exp (2 \pi i(\boldsymbol{k}-\boldsymbol{\ell}) \cdot \boldsymbol{x}) .
$$

Then we construct a real-valued function $g^{\star}$ defined on $[0,1)^{d}$ by taking the average of $\tilde{g}$ and its complex conjugate: $g^{\star}(\boldsymbol{x})=(\tilde{g}(\boldsymbol{x})+\overline{\tilde{g}(\boldsymbol{x})}) / 2$. Regarding the norm of $g^{\star}$ in $F_{d}^{1}$, we have

$$
\begin{aligned}
\left\|g^{\star}\right\| & \leq \frac{\|\tilde{g}\|+\|\tilde{\tilde{g}}\|}{2}=\|\tilde{g}\|=C \sum_{\boldsymbol{k} \in \mathcal{A}}\left|c_{\boldsymbol{k}}\right| \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right) \\
& \leq C \sum_{\boldsymbol{k} \in \mathcal{A}} \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right) \leq C \max _{\boldsymbol{\ell} \in \mathcal{A}} \sum_{\boldsymbol{k} \in \mathcal{A}} \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right)
\end{aligned}
$$

To ensure $\left\|g^{\star}\right\| \leq 1$, we set

$$
C=\left(\max _{\ell \in \mathcal{A}} \sum_{\boldsymbol{k} \in \mathcal{A}} \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right)\right)^{-1} .
$$

By construction, we have $g^{\star}\left(\boldsymbol{x}_{h}\right)=0$ for all $h=0, \ldots, n-1$, which implies $Q_{n, d}\left(g^{\star}\right)=0$. On the other hand, the exact integral is given by

$$
I_{d}\left(g^{\star}\right)=C c_{\boldsymbol{\ell}}=C=\left(\max _{\boldsymbol{\ell} \in \mathcal{A}} \sum_{\boldsymbol{k} \in \mathcal{A}} \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right)\right)^{-1}
$$

Since $g^{\star} \in F_{d}^{1}$ with $\left\|g^{\star}\right\| \leq 1$, the worst-case error of any linear algorithm $Q_{d, n}$ is bounded below by

$$
e^{\mathrm{wor}}\left(F_{d}^{1}, Q_{d, n}\right) \geq\left|I_{d}\left(g^{\star}\right)-Q_{n, d}\left(g^{\star}\right)\right|=\left(\max _{\boldsymbol{\ell} \in \mathcal{A}} \sum_{\boldsymbol{k} \in \mathcal{A}} \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right)\right)^{-1}
$$

In what follows, let

$$
\mathcal{A}=\{\mathbf{0}\} \cup\left\{\boldsymbol{k} \in \mathbb{Z}^{d} \mid d-1 \text { of } k_{j} \text { are all } 0 \text { and one non-zero } k_{j} \text { is from }\{1, \ldots,\lceil n / d\rceil\}\right\} .
$$

It is easy to verify that $|\mathcal{A}|=1+d\lceil n / d\rceil>n$. For this choice of $\mathcal{A}$, we can restrict ourselves to $\ell=(\ell, 0, \ldots, 0)$ for some $\ell \in\{0, \ldots,\lceil n / d\rceil\}$. By utilizing the assumption $n>2 d$ and the well-known inequality $\log x \leq x-1$, we have

$$
\begin{aligned}
& \sum_{k \in \mathcal{A}} \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right) \\
& =\max (1, \log \ell)+\sum_{k_{1}=1}^{\lceil n / d\rceil} \max \left(1, \log \left|k_{1}-\ell\right|\right)+\sum_{j=2}^{d} \sum_{k_{j}=1}^{\lceil n / d\rceil} \max \left(1, \log k_{j}\right) \\
& \leq \log \lceil n / d\rceil+d \sum_{k=1}^{\lceil n / d\rceil} \max (1, \log k) \\
& \leq \log \lceil n / d\rceil+d\lceil n / d\rceil \log \lceil n / d\rceil \\
& \leq(\lceil n / d\rceil-1) \cdot(1+d\lceil n / d\rceil) \leq \frac{2 n^{2}}{d}
\end{aligned}
$$

Since the last bound is independent of $\ell$, we obtain

$$
e^{\mathrm{wor}}\left(F_{d}^{1}, Q_{d, n}\right) \geq\left(\max _{\ell \in \mathcal{A}} \sum_{\boldsymbol{k} \in \mathcal{A}} \max \left(1, \min _{j \in \operatorname{supp}(\boldsymbol{k})} \log \left|k_{j}-\ell_{j}\right|\right)\right)^{-1} \geq \frac{d}{2 n^{2}}
$$

This completes the proof.
