A collective excitation of the spin structure in a magnetic insulator can transmit spin-angular momentum with negligible dissipation¹⁻⁵. This quantum of a spin wave, introduced more than nine decades ago⁶, has always been manipulated through magnetic dipoles⁷⁻¹⁰, (*i.e.*, time-reversal symmetry). Here, we report the experimental observation of chiral-spin transport in multiferroic BiFeO₃, where the spin transport is controlled by reversing the ferroelectric polarization (*i.e.*, spatial inversion symmetry). The ferroelectrically controlled magnons produce an unprecedented ratio of up to 18% rectification at room temperature. The spin torque that the magnons in BiFeO₃ carry can be used to efficiently switch the magnetization of adja-

cent magnets, with a spin-torque efficiency being comparable to the spin Hall effect in heavy metals. Utilizing such a controllable magnon **generation and transmission** in BiFeO_3 , an all-oxide, energy-scalable logic is demonstrated composed of spin-orbit injection, detection, and magnetoelectric control. This observation opens a new chapter of multiferroic magnons and paves an alternative pathway towards low-dissipation nanoelectronics.

Intense studies of spin current transport in magnetic insulators^{4,11–14} have opened various avenues for research on spintronics^{15–21} and their potential use in low-power applications¹³. This trend has also triggered renewed interest in magnon physics, which can be controlled via time-reversal-symmetry design (*e.g.*, magnetic domain walls⁷, spin Hall currents^{8,9}, static magnetic fields¹⁰). On the other hand, recent works have shown that broken inversion symmetry and the resulting Dzyaloshinskii-Moriya interaction (DMI) **have profound influence on** magnon transport in non-centrosymmetric magnets^{22–24}. In this spirit, multiferroics are potentially of great interest, since they display broken inversion symmetry and a ferroelectric polarization that can be switched by the application of an electric field, which in turn allows for control of the magnetism and, potentially, the magnons. The idea that multiferroics could be promising candidates for magnonic manipulation has been considered for some time^{13,25}, but despite this early interest, observation and manipulation of magnon transport in multiferroics - that is, the capability to manipulate spin transport via ferroelectric polarization reversal and resultant DMI switching- remain elusive.

Here, we demonstrate non-volatile, bistable spin transport in multiferroic BiFeO_3 upon reversing the ferroelectric polarization. BiFeO_3 is a model multiferroic that exhibits multiple order parameters (*i.e.*, antiferromagnetism and ferroelectricity) and intrinsic magnetoelectric coupling of these coexisting order parameters^{26,27}. In the bulk, BiFeO_3 possesses a rhombohedrally distorted perovskite structure in which a spin cycloid²⁸ is formed with a period length of ~ 64 nm^{29,30} and a Néel temperature of ~ 643 K³¹. The DMI in BiFeO_3 thin films can influence the spin cycloid order^{13,32,33}. At the same time, BiFeO_3 thin films possess robust ferroelectricity, with a Curie temperature ~ 1100 K and a large polarization $> 90 \mu\text{C}/\text{cm}^2$ ³⁴. In turn, BiFeO_3 exhibits outstanding magnetoelectric properties which have made it the focus of numerous studies hoping to utilize it as a platform to achieve low-energy (low-voltage) memory devices (*e.g.*, deterministic switching of adjacent ferromagnets³⁵). Specifically, achieving control over changing the magnetization states through ferroelectric polarization switching has always been a keen pursuit in these studies.

As illustrated in Fig. 1a, a spin cycloid propagating along $\mathbf{q} = [\bar{1}\bar{1}0]$ is revealed by Nitrogen-Vacancy diamond magnetometry measurements (Extended Data Fig. 1), which is in good agreement with the pioneering work of Gross et al^{29,30}. The formation of spin cycloid has been explained in terms of a Lifshitz-like invariant³⁶ which, in the continuum limit, amounts to an effective DMI vector \mathbf{D}_0 perpendicular to both the ferroelectric polarization \mathbf{P} (along $[111]$) and the spin cycloid propagating direction \mathbf{q} . In BiFeO_3 , there is another intrinsic DMI characterized by a global DMI vector parallel to \mathbf{P} , which is responsible for the small magnetization \mathbf{m} everywhere perpendicular to the Néel vector \mathbf{L} . Previous studies have confirmed that the latter mechanism is much weaker

so that the spin texture is dominated by \mathbf{D}_0 ^{36,37}. A reversal of \mathbf{P} is accompanied by the reversal of the octahedral antiphase tilts³⁵, which in turn flips the direction of \mathbf{D}_0 ^{33,36}. In addition, the asymmetric gates, the existence of ferroelectric domain walls³⁸, and other asymmetries of external origins generate a built-in potential that induces an additional DMI vector $\delta\mathbf{D}$, which remains the same under the reversal of \mathbf{P} . Consequently, the total DMI vector $\mathbf{D}_0 + \delta\mathbf{D}$ undergoes a non-180° switching, leading to a slight rotation of the propagation direction \mathbf{q} . To intuitively understand the ferroelectric control of magnon spin current, we define the hybrid product $(\mathbf{D}_0 \times \delta\mathbf{D}) \cdot \mathbf{K}$ where \mathbf{K} is the magnon wave vector (in the thickness direction). It is well-known that the non-reciprocal propagation is allowed not only in magnons but also electrons, electromagnetic waves when they go through materials such as multiferroic materials that host broken time reversal and space inversion symmetry simultaneously. As illustrated in Fig. 1a, reversing \mathbf{P} necessarily flips the sign of $(\mathbf{D}_0 \times \delta\mathbf{D}) \cdot \mathbf{K}$, hence the chirality of these three vectors. This hybrid product can also reflect a *directional* non-reciprocity where the wave vector \mathbf{K} flips sign^{22–24,39} while the DMI is kept unchanged. In other words, this single quantity captures the common feature of both directional non-reciprocity and ferroelectric modulation of the magnon spin current.

Because the thickness of BiFeO₃ is much smaller than the spacial period (~64 nm) of the spin cycloid, we can ignore any spin texture or magnetic inhomogeneity along the magnon wave vector \mathbf{K} . Then, the transmitted spin current can be phenomenologically expressed as¹⁵

$$J_s = \frac{G_L}{S} \int d\mathbf{r}^2 [\mathbf{L}(\mathbf{r}) \cdot \mathbf{s}]^2 + \frac{G_m}{S} \int d\mathbf{r}^2 [\mathbf{m}(\mathbf{r}) \cdot \mathbf{s}]^2, \quad (1)$$

where G_L (G_m) is the phenomenological spin conductance of the Néel vector (total magnetization), $\mathbf{s} = \hat{y}$ is the polarization of spin injection from the top gate and S is the area of the film. As mentioned above, when the total DMI vector undergoes a non-180° switching, the spin cycloid profile functions $\mathbf{L}(\mathbf{r})$ and $\mathbf{m}(\mathbf{r})$ are modulated by \mathbf{P} in a non-trivial way. As calculated in the Supplemental Materials, the resulting spin current J_s can be substantially different before and after the reversal of \mathbf{P} . To quantify this difference, we define the rectification ratio as

$$\xi = \frac{J_s(-\mathbf{P}) - J_s(\mathbf{P})}{J_s(-\mathbf{P}) + J_s(\mathbf{P})} \quad (2)$$

and plot it against the orientation of the extrinsic $\delta\mathbf{D}$ relative to the intrinsic \mathbf{D}_0 (along $[\bar{1}\bar{1}2]$) in Fig. 1b, where we have marked the experimental value (to be explained below) $\xi = 0.17857$.

Based on the predicted potential for chiral-magnon control in BiFeO₃, a demonstration of a scalable magnetoelectric spin-orbit logic was investigated. A schematic of this idea is illustrated in Fig. 1d. An electric field is set up in the magnetoelectric capacitor in the $-z$ direction, resulting in the vertical component of the ferroelectricity switching from the z to the $-z$ direction. To read the polarization state, a supply voltage is applied into the top spin-orbit coupled (SOC) channel (*e.g.*, SrIrO₃ which has a relatively large spin Hall angle⁴⁰) in the $+x$ direction, causing the excitation of magnons in the BiFeO₃ via the spin current from the SOC material. The readout of the state of the switch is then enabled by the inverse spin Hall effect using SrIrO₃⁴¹, where the current direction

is along the x direction. Owing to the magnon propagation with bistable rectification, the output voltage could acquire two stable states, rendering the buffer function of a logic gate. Especially, as compared with the first magneto-electric, spin-orbit (MESO) device proposal⁴², this design makes use of antiferromagnetic magnon to gauge the antiferromagnetism inside the multiferroic itself instead of relying on the adjacent ferromagnet coupled to the multiferroic (Extended Data Fig. 2). Early efforts on the elimination of the ferromagnet have been devoted to the electric-field controlled spin-orbit interaction^{43,44}, e.g. Rashba effect in two-dimensional electron gas systems^{45,46}. The elimination of the ferromagnet simplifies the readout architecture; furthermore, the implementation of antiferromagnets can favor ultrafast operations frequency up to THz.

To experimentally explore the controllable spin transmission enabled by the ferroelectric switch in BiFeO₃, we first characterized the strength of spin transmission via magnons in the heterostructures of the form La_{0.7}Sr_{0.3}MnO₃/BiFeO₃/SrIrO₃ (Methods, Extended Data Fig. 3,4). We performed the measurement using a well-established technique namely spin-torque ferromagnetic resonance (ST-FMR)^{40,47} (Fig. 2a), launching the spin current using the large spin Hall effect of SrIrO₃ and detecting the spin torque applied to the magnetic La_{0.7}Sr_{0.3}MnO₃ layer⁴⁸. An example ST-FMR spectrum, composed of both symmetric and anti-symmetric components, is shown (Fig. 2b) and indicates the successful detection of the spin currents carried by magnons through the BiFeO₃. To manipulate the orientation of the ferroelectric polarization, an external electric field was applied along the out-of-plane [001] to set the ferroelectric polarization of the BiFeO₃ as illustrated (top panel, Fig. 2c, in which the top SrIrO₃ and bottom La_{0.7}Sr_{0.3}MnO₃ layers serve as the two electrodes sandwiching the ferroelectric). Specifically, upward- (downward-) pointing polarization (180° switching) can be achieved by applying negative (positive) voltage larger than the coercivity of the BiFeO₃ on the top SrIrO₃ layer (bottom panel, Fig. 2c)⁴¹. After poling the BiFeO₃ in each individual device to the desired polarization state, we then deposited platinum contacts onto the devices (contacting both the SrIrO₃ and La_{0.7}Sr_{0.3}MnO₃ layers) and performed ST-FMR measurements on the poled devices. By adopting an established analysis method (Methods), the SOT efficiency for the damping-like (DL) torque (symmetric component) is evaluated and summarized (Fig. 2d). We observe that the SOT efficiency can be set at a high value by negative (upward polarization) or at a low value by positive (downward polarization) voltages, indicating the presence of bistable high/low spin transport in BiFeO₃. This polarization-dependent spin transmission of BiFeO₃ is also verified by interfacial engineering (Extended Data Fig. 5), time-resolved X-ray ferromagnetic resonance (Extended Data Fig. 6) and FMR measurements (Extended Data Fig. 7, 8). The blocking temperature of exchange bias between La_{0.7}Sr_{0.3}MnO₃ and BiFeO₃ is well below room temperature⁴⁹, and the absence of exchange bias is also confirmed by our magneto-optic Kerr effect measurements (Extended Data Fig. 9), ruling out the possible contribution from exchange bias on the tuning of spin transmission. It is worthwhile to note that the stability of the ferroelectric polarization reveals another crucial advantage associated with spintronics produced in this manner – non-volatility. By setting the polarization direction, high and low SOT efficiencies of 0.33 and 0.23 can be achieved, showing a high/low ratio of approximately 0.18%. Furthermore, the ferroelectric polarization controlled spin transmission in BiFeO₃ is confirmed by ST-FMR measurements on samples with opposite polarizations set by different interface terminations⁵⁰ (Extended

Data Fig. 5). This is consistent with our theoretical predictions that the polarization state influences magnon propagation and a spin transmission modulation can be achieved upon ferroelectric polarization switching. Further, from the aforementioned experiments it can be inferred that the spin transmission is favorable when the magnon wave vector is anti-parallel to the z-component of the polarization \mathbf{P} .

To corroborate the presence of a magnon transmission modulation in BiFeO₃, magnetization switching experiments were carried out to serve as a direct demonstration of the strength of the spin torques under ferroelectric polarization modulation. Here, we investigate deterministic magnetization switching of a SrRuO₃ layer with perpendicular magnetic anisotropy (PMA) by the spin torque carried by the BiFeO₃. Current-induced magnetization switching measurements were carried out for SrRuO₃ (5 nm)/BiFeO₃ (25 nm)/SrIrO₃ (10 nm) heterostructure with BiFeO₃ polarized to either upward or downward orientations (Fig. 3a). The switching schematic is also demonstrated (Fig. 3a), where the magnetic moment of the ferromagnetic SrRuO₃ is switched between positive and negative directions consistently and reversibly. The magnetic switching was detected by the anomalous Hall effect in the SrRuO₃ layer, in which magnetic moments lying on the positive and negative directions can be distinguished by positive and negative values of anomalous Hall resistance. By sweeping an external magnetic field in the out-of-plane direction (Fig. 3b), a hysteretic loop is developed for anomalous Hall resistance (R_{XY}), when the external magnetic field exceeds the coercivity of SrRuO₃ (Fig. 3b). Furthermore, R_{XY} as a function of magnetic field was repeated at temperatures from 20 K to 80 K, confirming the high quality of our heterostructure, and no shift in the hysteretic loop with respect to zero magnetic field is observed, indicating the absence of exchange bias effect between ferromagnetic SrRuO₃ and antiferromagnetic BiFeO₃. Then magnetization switching measurements were performed in the same device, and R_{XY} as a function of current pulses was recorded. Notably, a switching of magnetization was observed by both positive and negative currents, when the magnitudes of current pulses exceed the magnitude of critical switching current, and a saturation of R_{XY} is observed with large current pulses, excluding the possible participation of thermal effects in the switching measurements. Moreover, no magnetization switching is observed at zero assisting magnetic field and the switching chirality can be changed by the reversal of polarity of assisting magnetic fields, ruling out the possibility that the magnetization switching is caused by current-induced Oersted field. To further corroborate our observation of ferroelectric polarization-controlled spin transport with ST-FMR, ferroelectric polarization-dependent magnetization switching measurements were carried out. To start with, the polarization of BiFeO₃ was switched to either an upward or downward orientation by an external electric field. An example IV curve during the ferroelectric polarization switching measurements is displayed in Fig. 3d, in which the switching of ferroelectric polarization is associated with current peaks in Fig. 3d. Then, the same magnetization switching measurements were conducted on devices with distinct ferroelectric polarization states. A typical switching loop for heterostructures with upward (downward) polarization is displayed in red (blue) solid spheres in Fig. 3e. Strikingly, distinct critical switching currents for upward and downward polarization were observed in both positive and negative current directions. The critical switching currents at different assisting magnetic fields for upward and downward polarization are summarized in Fig. 3f, where upward

polarization shows a smaller switching current than downward polarization statistically. Therefore, two conclusions can be drawn based on our experimental observations. First, BiFeO₃ has the capability to carry spin information via antiferromagnet magnons, and the spin torque arising from BiFeO₃ is sufficiently efficient to switch the magnetization of SrRuO₃. More importantly, the spin transmission in BiFeO₃ is controlled by ferroelectric polarization, and the smaller critical switching current density for the upward polarization corresponds to a higher spin transmission, in good agreement with the ferroelectric polarization controlled-SOT efficiency study with the ST-FMR technique. The current-induced magnetization switching measurements reinforce the idea that the upward polarization is favorable for magnon transmission.

We further investigated the experimental demonstration of MESO via electrically controllable spin transport [using a lateral nonlocal measurement](#). A schematic of the nonlocal measurement is provided (Fig. 4a); it consists of spin-orbit input and output via parallel source and detector wires, as well as magnetoelectric control. Fig. 4b illustrates well-ordered 71° ferroelectric domains, showing the high quality of the BiFeO₃ films. A nonlocal, quasi-static measurement was performed (Fig. 4c), varying the magnitude of the electric-field pulse applied in-plane across the channel from negative to positive and back again, and after each pulse measuring (over 100 seconds) non-local voltage signals due to magnon transport between the source and detector wires [\(Methods\)](#). We observe a butterfly-shaped and hysteretic response in the magnon current launched by the spin Hall effect (first-harmonic voltage, Fig. 4c) and the magnon current launched thermally by the local spin Seebeck effect, respectively (second-harmonic voltage, Fig. 4d), in which the coercive fields match each other. [Besides, the electric field modulations of the output voltage can be obtained with dc methods, which can minimize the inductive and capacitive effect \(Extended Data Fig. 10,11\)](#). Figure 4e presents measurements of the magnitude of these spin-transport signals as a function of changing the spacing between the source and detector wires from 500 nm to 4 μm. The open squares reflect the magnitude of the signals associated with spin currents launched by the spin Hall effect (first harmonic voltage) and the red circles reflect signals launched thermally by the spin Seebeck effect (second harmonic voltage). Remarkably, the output voltage detected in BiFeO₃/SrIrO₃ stacks ($\sim 1 \mu\text{V}$) is approximately one order of magnitude larger than the counterparts in BiFeO₃/Pt ($\sim 0.1 \mu\text{V}$)⁵¹, which is supported by the large spin-torque efficiency of SrIrO₃ previously observed with the ST-FMR measurement^{40,52} [and the controlled nonlocal measurements of NiFe₂O₄/Pt and NiFe₂O₄/SrIrO₃ \(Extended Data Fig. 13,14\)](#). The distance dependence for both types of signals in BiFeO₃ fits well to the expectation for diffusive magnon propagation⁵³

$$R_{\text{nl}} = \frac{C}{\lambda} \frac{\exp(d/\lambda)}{1 - \exp(2d/\lambda)} \quad (3)$$

with effective diffusion lengths $\sim 0.17 \mu\text{m}$ (first harmonic) and $\sim 0.25 \mu\text{m}$ (second harmonic).

Using this result and the spin-torque efficiencies obtained above [\(Extended Data Fig. 5\)](#), we can calculate the inverse-spin-Hall output voltage that would be obtained for a vertical geometry

with BiFeO₃ thicknesses of 10 and 15 nm using⁵⁴

$$V_{\text{ISHE}} = \frac{\theta_{\text{SOT}} \lambda_{\text{SD}} \tanh(\frac{t_{\text{SIO}}}{2\lambda_{\text{SD}}}) L}{t_{\text{SIO}} \sigma_{\text{SIO}}} J_{\text{S}} \quad (4)$$

where we use the values $\theta_{\text{SOT}} = 0.4$ is the spin-torque efficiency, $\lambda_{\text{SD}} = 1.4 \text{ nm}$ ⁵⁵ is the spin-diffusion length of SrIrO₃, $t_{\text{SIO}} = 10 \text{ nm}$ is the thickness, $\sigma_{\text{SIO}} = 1 \times 10^5 \Omega^{-1} \text{m}^{-1}$ is the conductivity, $L = 10 \text{ nm}$ is the wire length. The output voltage is on the order of 10 mV, which is approaching the MESO target voltage of 100 mV. A prototypical magnon-mediated MESO logic device and its circuit modeling utilizing this ferroelectrically controlled magnon propagation are shown in Extended Data Fig. 5. This observation sheds light on implementing multiferroics as the potential spin carriers and opens new possibilities of energy-efficient magnonic spin-logic devices.

Methods

Sample and device fabrication

The tri-layers used in this study were grown by RHEED assisted pulsed laser deposition using a

KrF laser with a wavelength of 248 nm. A 20 nm $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ (5 nm SrRuO_3) layer was first grown at a substrate temperature 700°C and oxygen partial pressure 150 mTorr (100 mTorr), then a BiFeO_3 layer followed with various thicknesses at a substrate temperature 700°C and oxygen partial pressure 100 mTorr, and finally a 10 nm SrIrO_3 layer finished the growth at a substrate temperature 700°C and oxygen partial pressure 50 mTorr. The films were grown at a repetition of 2 (5 Hz) Hz, 10 Hz and 5 Hz with a laser fluence of 1.5 J/cm², 1.5 J/cm² and 1.2 J/cm², respectively. After the growth, the sample was cooled to room temperature in an oxygen environment of 750 Torr at a cooling rate of 10°C/min. To make ST-FMR devices, the samples were first spin coated with photoresist (MiR 701), then devices with a $50 \times 25 \mu\text{m}^2$ rectangular dimensions ($15 \times 10 \mu\text{m}^2$ for the electric-field-controlled experiment) were made by photolithography (Heidelberg MLA 150) followed by ion milling (Pi scientific) that stopped at the $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ layer. The remaining $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ layer was used as the bottom electrode in the switching experiments; for the ST-FMR measurements this was patterned using a H_3PO_4 wet etch ($\text{H}_3\text{PO}_4 : \text{H}_2\text{O} = 1 : 3$). Finally, electrical contacts were made from 100 nm of Pt with a ground-signal-ground (GSG) geometry, so that when a GSG high-frequency probe made into contact with the samples the current traveling through the Pt contacts did not produce a net Oersted field at the sample.

Antiferromagnetic spin wave calculations

To perform the spin wave calculations, we first prepare a polar ground state corresponding to $\mathbf{P}||[111]$ and $\mathbf{P}||[\bar{1}\bar{1}\bar{1}]$ (along with an order parameter for the octahedral antiphase tilts). We then evolve the LLG-LLB equation to find the magnetic ground state corresponding to $\mathbf{L}||[\bar{1}01]$ with $\mathbf{m}||[1\bar{2}1]$ and $\mathbf{m}||[\bar{1}2\bar{1}]$. To study the spin waves, the homogeneous magnetic ground state is perturbed with an applied field $\mathbf{H}||[\bar{1}01]$ with Gilbert damping $\alpha = 0$, and the spin waves are set to propagate along $\pm\mathbf{k}||[001]$. The detectable spin current in the AFM insulating layer⁵⁶ are proportional to $\mathbf{j} = \mathbf{j}^l + \mathbf{j}^m + \mathbf{j}^{ml} + \mathbf{j}^{lm}$ where $\mathbf{j}^l \propto \mathbf{l} \times \dot{\mathbf{l}}$, $\mathbf{j}^m \propto \mathbf{m} \times \dot{\mathbf{m}}$, $\mathbf{j}^{ml} \propto \mathbf{m} \times \dot{\mathbf{l}}$, and $\mathbf{j}^{lm} \propto \mathbf{l} \times \dot{\mathbf{m}}$. More details of our simulations are provided in the SM. Calculations are performed using the Ferret module⁵⁷ which is part of the open-source MOOSE framework⁵⁸.

ST-FMR analysis

The ST-FMR signal, V_{mix} , is produced across the $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3/\text{SrIrO}_3$ ST-FMR device as rectification of anisotropic magnetoresistance that oscillates at the same frequency as the input microwave current I_{RF} ⁵⁹. A microwave current at frequencies 4-6 GHz and power 12 dBm is applied to the device, with an in-plane external magnetic field oriented 45° with respect to the current direction. Finally, $V_{mix} = -\frac{1}{4} \frac{dR}{d\theta} \frac{\gamma I_{RF} \cos\theta}{2\pi\Delta(df/dH)_{H_{ext}=H_0}} (\tau_{DL} F_S(H_{ext}) + \tau_{FL} F_A(H_{ext}))$ ⁵⁹, where $dR/d\theta$ is the angle dependent magnetoresistance at θ , γ is the gyromagnetic ratio, Δ is the linewidth of the ST-FMR signal, $(df/dH)_{H_{ext}=H_0}$ is the field gradient of the resonance frequency, τ_{DL} is the damping-like torque, τ_{FL} is the field-like torque, $F_S(H_{ext})$ is the symmetric Lorentzian function and $F_A(H_{ext})$ is the anti-symmetric Lorentzian function respectively, is detected by Keithley 2182A nanovoltmeter, from the fits of which the symmetric component V_S and the anti-symmetric component V_A , which are associated with damping-like torque (τ_{DL}) and field-

like torque (τ_{FL}) respectively, can be extracted. As a result, spin orbit torque efficiency- ξ_{SOT} is

evaluated using $\xi_{DL} = \frac{2e\tau_{DL}m_s t_{FM}}{J_c \hbar}$, where $\tau_{DL} = \frac{4V_s \Delta}{I_{RF} \cos \theta} \frac{1 + \frac{\mu_0 M_{eff}}{2B_{res}}}{\frac{dR}{d\theta} (\frac{1 + \mu_0 M_{eff}}{B_{res}})^{1/2}}$ ^{60,61}. The SOT

efficiency for the samples in this work was measured from 4 GHz to 6 GHz and the error bar in Fig. 2 is a result of SOT efficiencies across different frequencies, while the error bar in extended Fig. 5 is caused by the SOT efficiency distribution across different devices.

Parameters for non-local spin transport measurements

The length of the wire is 100 μm , the applied voltage is 20V, the applied current is 10 μA , the alternating current frequency is 7 Hz.

Data availability

The data that support the findings of this study are available from the corresponding authors on reasonable request.

Acknowledgements

We are grateful for the fruitful discussions with Prof. Albert Fert, Dr. Eric Parsonnet, Dr. Yenlin Huang. X.H., D.C.R. and R.R. acknowledge the support from the SRC-JUMP ASCENT center. R.J. acknowledges the support from the U.S. Department of Energy, under contract No. DE-SC0017671. Author contributions

X.C. and R.R. supervised this study. X.H. carried out the synthesis and characterization of het-

erostructures. X.H. and X.C. fabricated the devices. X.H. and R.J. carried out the ST-FMR measurements. X.H. and X.C. carried out the current induced magnetization switching measurements. C.X. H.T. performed the non-local transport measurements. C.K. performed dynamic XMCD measurements at beamline 4.0.2 of the Advanced Light Source. Y.L. and R.C performed the theoretical calculations. J.M., D.R.R. O.H., and J.I. developed and performed the coupled polar-micromagnetic simulations. X.C., D.V., and Z.Y. devised the electronic model and performed the calculations. S.S. performed the microstructure and electronic structure characterizations. H.Z., T.W., L.C., C.H., I.H., H.P., J.Y., P.M., P.S., Z.Q., S.S., M.R., D.S., L.W.M., D.C.R., and A.F. gave suggestions on the experiments. All authors discussed the results and prepared the manuscript.

Figure 1: Concept of chiral magnon transport in multiferroics. **a**, A sketch of spin cycloid that propagates along $q = [1\bar{1}0]$. P is the ferroelectric polarization pointing along $[111]$, D_0 (along $[\bar{1}\bar{1}2]$) is the intrinsic DMI vector responsible for the spin cycloid formation, and δD is the extrinsic DMI vector induced by the built-in electric field in BiFeO_3 . The double well is a schematic of the bi-stable states of ferroelectric polarization. Upon the reversal of P , D_0 switches by 180° while δD remains unchanged, flipping the sign of the hybrid product $(D_0 \times \delta D) \cdot K$ with K the magnon wave vector, hence a chirality flip of the three vectors. **b**, Rectification ratio of spin current [defined by Eq. (1)] as a function of $\delta\theta$ and $\delta\phi$, which are the spherical angles of δD relative to the direction of D_0 . The lime solid line marks the experimental value $\xi = 0.17857$. **c**, Buffer logic consists of spin injection in the top SOC layer (dark green), magnetoelectric control of spin transmission in the intermediate ME layer (translucent), and spin detection in the bottom SOC layer (dark green). The switching of the polar order is controlled by V_{in} . V_{supply} serves as the source for spin Hall current injection. The small (purple) and large (red) output voltages V_{out} in **c** correspond to spin transport of downward and upward ferroelectric polarization in **a** respectively.

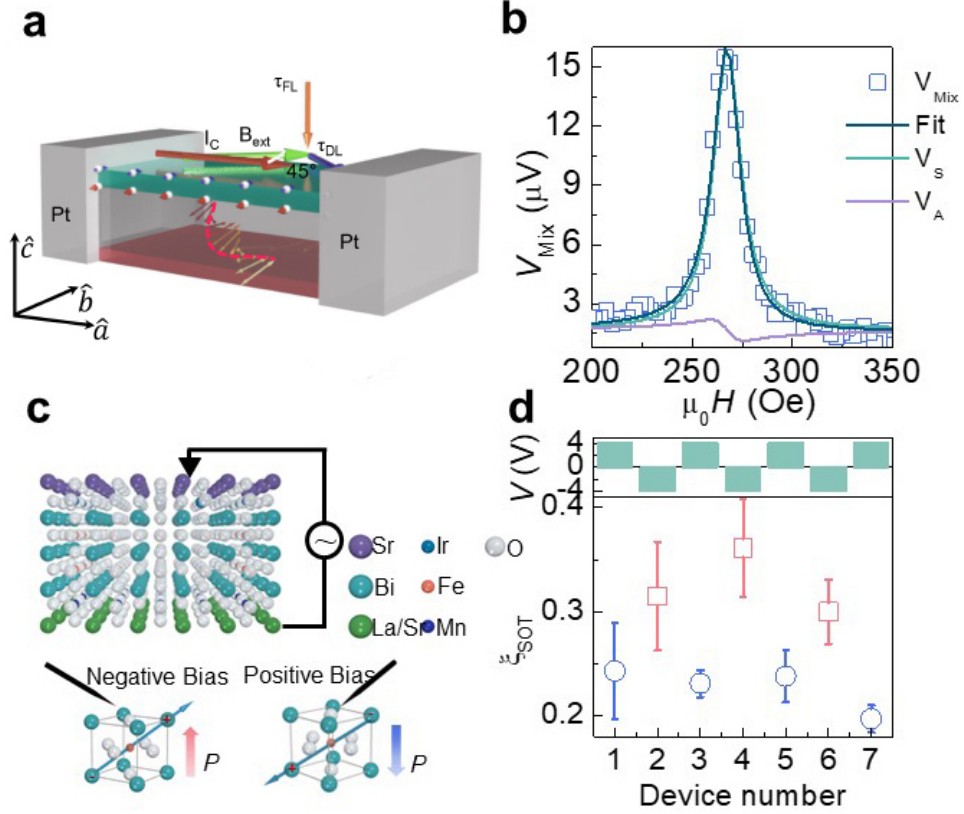

Figure 2: Spin transmission controlled by ferroelectric polarization in BiFeO₃. **a**, A 3D schematic illustration for the ST-FMR measurement. Top : SrIrO₃, middle : BiFeO₃, bottom : La_{0.7}Sr_{0.3}MnO₃. I_c represents the radio frequency microwave current, which flows at a 45° angle with respect to the in-plane external magnetic field represented by B_{ext} . A spin cycloid that lies in $(\bar{1}\bar{1}2)$ plane, and propagates along $[1\bar{1}0]$ direction is depicted by the double-headed arrows. **b**, Measured ST-FMR signal at room temperature for 12 dBm of applied microwave power at 4 GHz for a sample La_{0.7}Sr_{0.3}MnO₃ (20 nm)/BiFeO₃ (25 nm)/SrIrO₃ (10 nm) of dimension $50 \times 25 \mu m^2$. The lines are Lorentzian fits to the mixing voltage as described in methods (ST-FMR analysis section), showing both symmetric and anti-symmetric components. **c**, A schematic of a La_{0.7}Sr_{0.3}MnO₃ (20 nm) /BiFeO₃ (25 nm) /SrIrO₃ (10 nm) heterostructure subject to an external electric field, along with schematics of the BiFeO₃ ferroelectric polarization under negative and positive biases. **d**, The SOT efficiency measured with the ST-FMR technique as a function of bias voltages applied beforehand for samples of La_{0.7}Sr_{0.3}MnO₃ (20 nm) /BiFeO₃ (25 nm) /SrIrO₃ (10 nm) The open squares (circles) represent the SOT efficiency for the tri-layer with negative (positive) bias voltages applied on the top electrode - SrIrO₃.

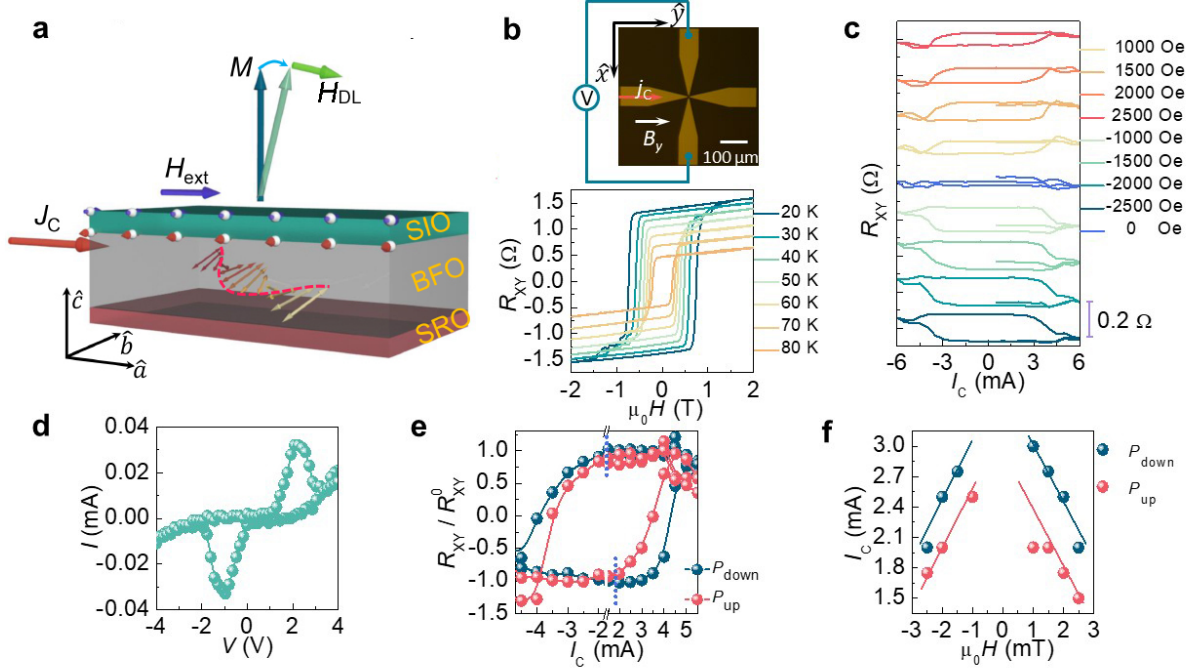

Figure 3: Magnetization switching induced by the spin torque in BiFeO₃ under the control of ferroelectric polarization. **a**, A schematic demonstrating the magnetization switching of SrRuO₃ by the current-induced torques borne by the magnons transmitted through BiFeO₃ for a sample SrRuO₃ (5 nm)/BiFeO₃ (25 nm)/SrIrO₃ (10 nm). A spin cycloid that lies in ($\bar{1}\bar{1}2$) plane, and propagates along $[1\bar{1}0]$ direction is depicted by the double-headed arrows. The torque carried by the transmitted magnons switches the magnetic moment (dark blue arrows) of the neighboring SrRuO₃ layer in the out-of-plane direction. A small assisting magnetic field (H_{ext}) is applied along the pulsed current (J_C) direction. **b**, An optical image of the actual Hall device used in the anomalous Hall effect (AHE) and magnetization switching measurements. Anomalous Hall resistance (R_{XY}) as a function of the magnetic field at various temperatures for the heterostructure SrRuO₃ (5 nm)/BiFeO₃ (25 nm)/SrIrO₃ (10 nm) is shown on the bottom. A dc current of 100 μ A is applied during the AHE measurements. **c**, R_{XY} as a function of pulsed currents. External magnetic fields with different polarities and strengths are applied along the current pulse direction to assist the magnetization switching. After each current pulse, a dc current of 100 μ A is applied to detect the change in R_{XY} . The hysteretic magnetization switching loops are shifted with respect to the magnetization switching loop at zero assisting field for display. The current pulses have a pulse width of 1 ms. **d**, An example IV curve collected during the ferroelectric switching experiments for the heterostructure SrRuO₃ (5 nm)/BiFeO₃ (25 nm)/SrIrO₃ (10 nm). **e**, An example ferroelectric polarization controlled magnetization switching measurement. The magnetization switching behavior for SrRuO₃ (5 nm)/BiFeO₃ (25 nm)/SrIrO₃ (10 nm) heterostructure with the polarization of BiFeO₃ pointing from the bottom (top) electrode to the top (bottom) electrode is shown in red (blue). The R_{XY} is normalized for better display. **f**, The magnitudes of critical switching current as a function of the applied external magnetic fields are summarized. The critical switching current for SrRuO₃ (5 nm)/BiFeO₃ (25 nm)/SrIrO₃ (10 nm) heterostructure with upward (downward) ferroelectric polarization is shown in red (blue). The lines are a guide to the eye.

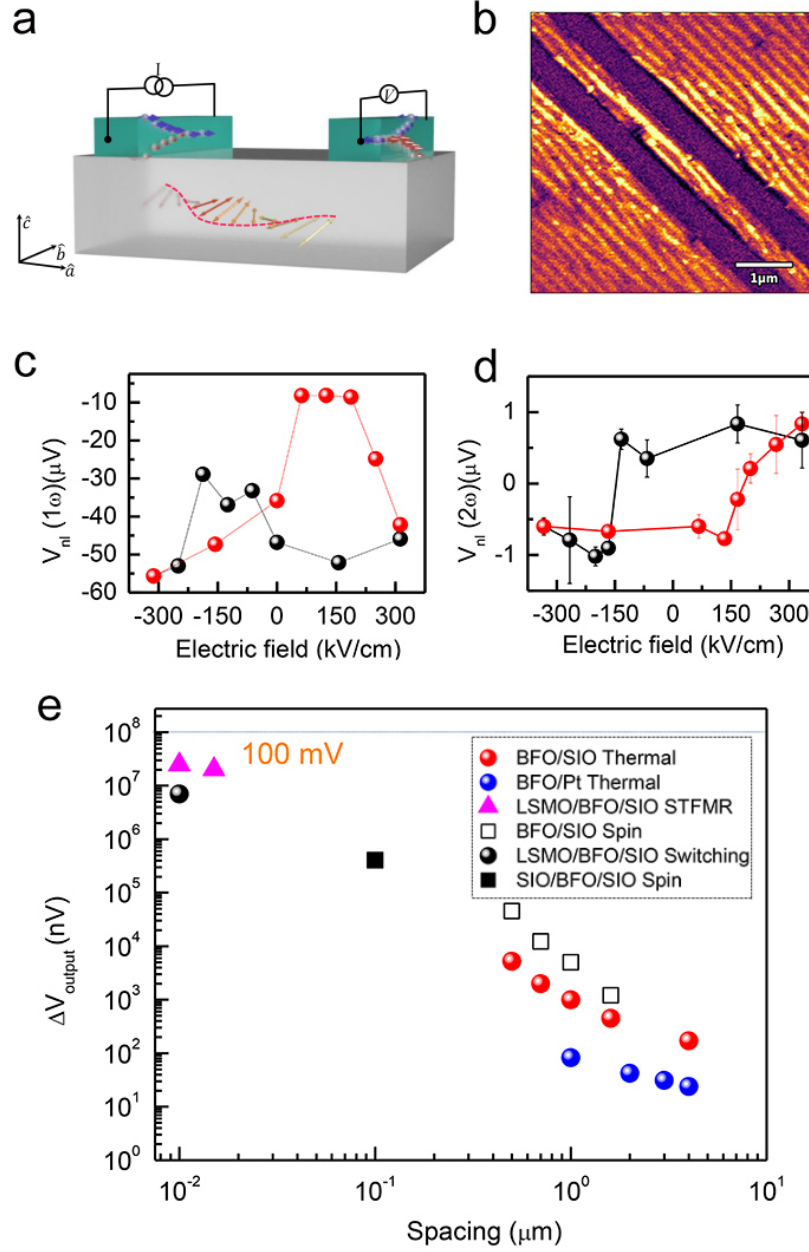

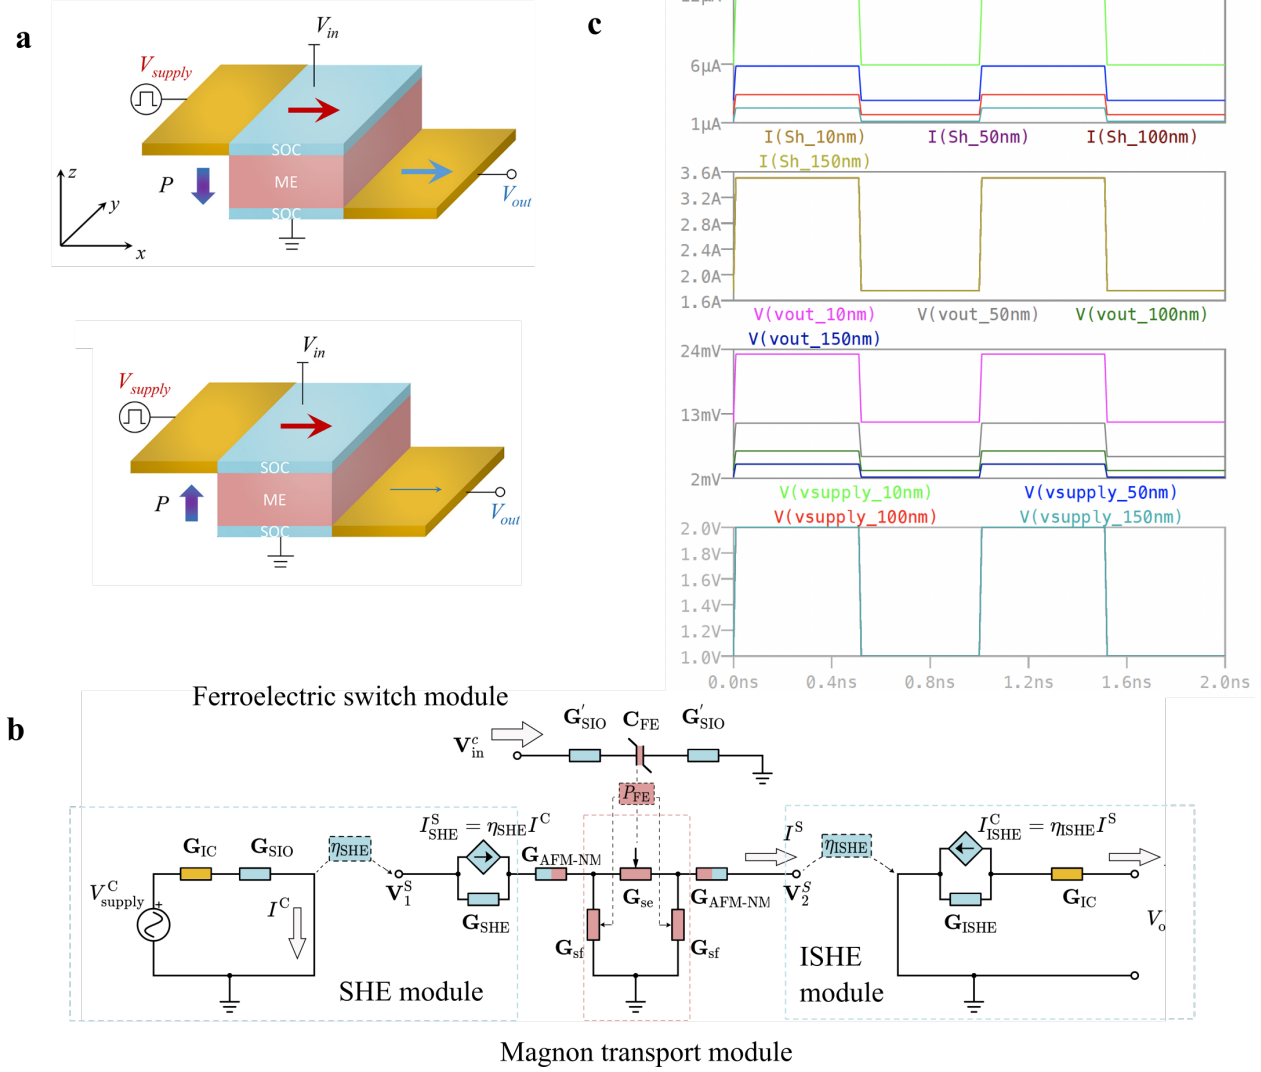

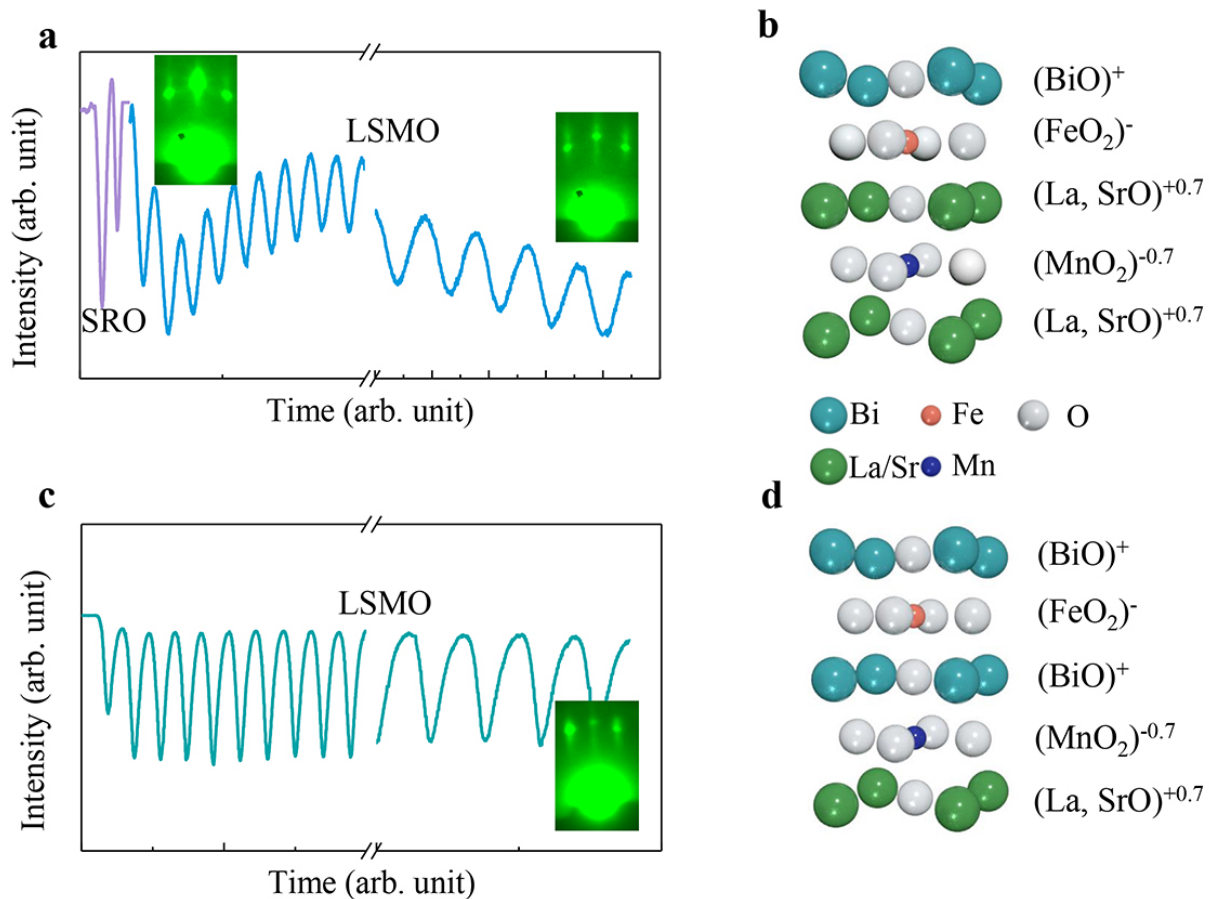

Figure 4: Magnetolectric spin-orbit logic based on controllable magnon transport in BiFeO_3 . **a**, Schematic of the non-local device formed with a magnetolectric test structure. **b**, Piezo-force microscopy image of the non-local device structure. The channel width is $0.5\mu\text{m}$. **c**, Hysteresis loop from spin magnon readout in SrIrO_3 with first harmonic measurements for a device with a 500 nm channel width. **d**, Hysteresis loop from thermal magnon readout in SrIrO_3 with second harmonic measurements in a device with a $1\mu\text{m}$ channel width. **e**, Output voltage scaling with channel spacing for measurements in nonlocal devices (points for spacings $0.5\mu\text{m}$ and above), vertical structure of SIO/BFO/SIO when BFO is 100 nm , and estimates of voltages that could be obtained for vertical transport of magnons through 10 and 15 nm of BiFeO_3 . The power is fixed at 3 mW .

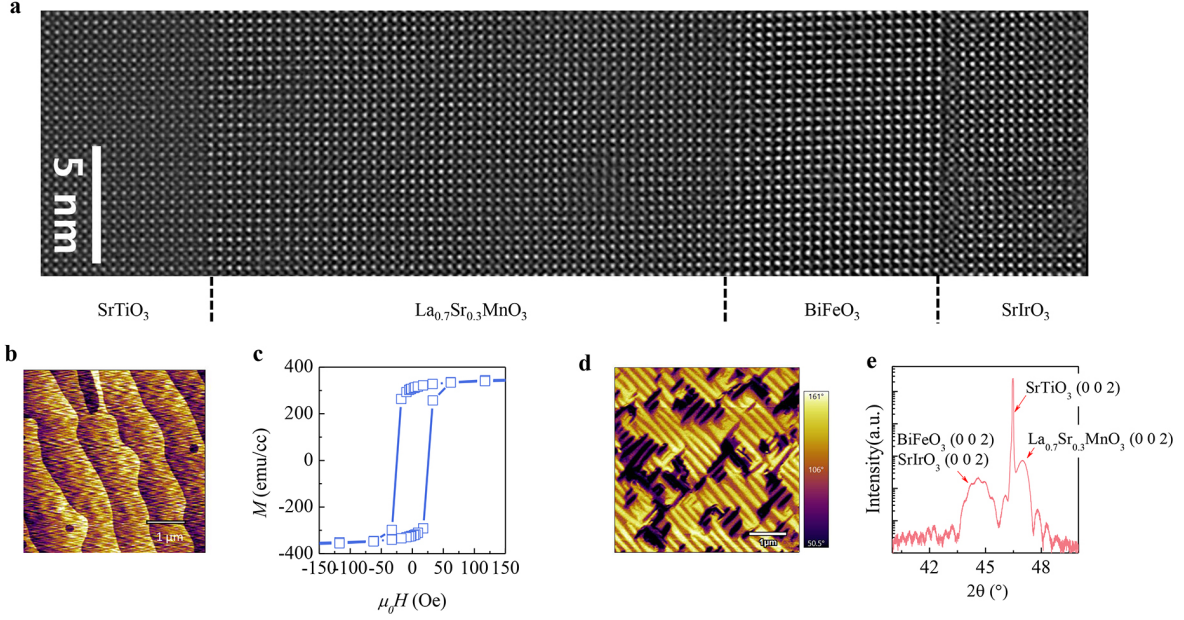

Extended Data Fig. 1. NV magnetometry image for BiFeO_3 . **a, c,** Schematic illustrations of ferroelectric domains and the corresponding spin cycloid propagation directions before and after polarization switching. The pink arrows represent the ferroelectric polarization orientations. **b, d,** Magnetic stray field distribution recorded with scanning NV magnetometer for 100 nm BiFeO_3 before and after polarization switching. The blue arrows are the spin cycloid propagation wave vector

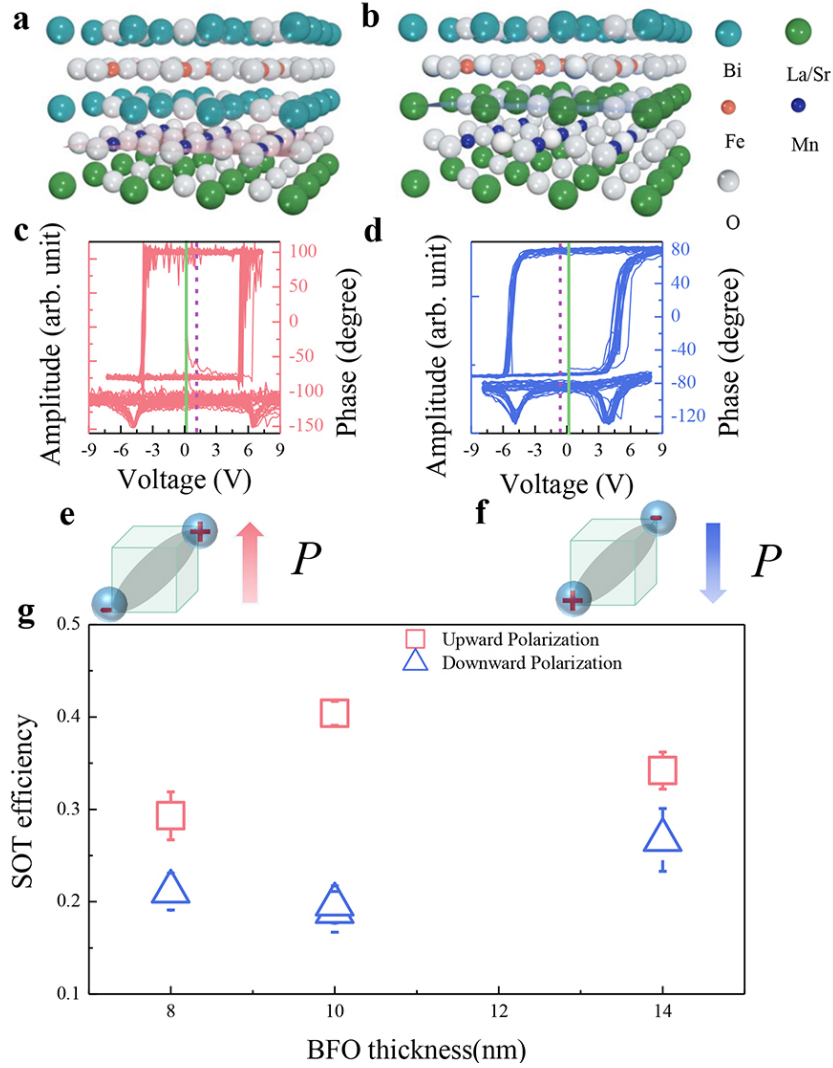

Extended Data Fig. 2. Schematics for magnon-mediated MESO logic device. **a**, Same schematics duplicated from Fig. 1d. **b**, Modularized circuit schematics. The top module is the ferroelectric switch module, where the input voltage V_{in}^c switches the direction of the ferroelectric polarization P_{FE} in the magnetoelectric layer. Such polarization change also affects the spin conductance G_{se} and G_{sf} of the ME layer. The leftmost and rightmost modules represent the spin Hall effect (SHE) process in the top SOC layer (injector) and the inverse spin Hall effect (ISHE) process in the bottom SOC layer (detector), respectively. The current-controlled spin current source I_{SHE}^S in the SHE module depends on the output charge current of the top SOC layer. Similarly, the current-controlled charge current source I_{ISHE}^C in the ISHE module depends on the output spin current of the bottom SOC layer. The parameters η_{SHE} and η_{ISHE} represent the charge-to-spin and spin-to-charge current conversion rates, respectively. The module in the middle describes the magnon transport process in the ME layer, which is connected to the SHE and ISHE modules through the spin conductance at the interfaces between ME and SOC layers, denoted as G_{AFM-NM} . **c**, Lossy Buffer logic simulation result for the equivalent circuit in Fig. 2.b where the output follows the input pulse signal characteristics.

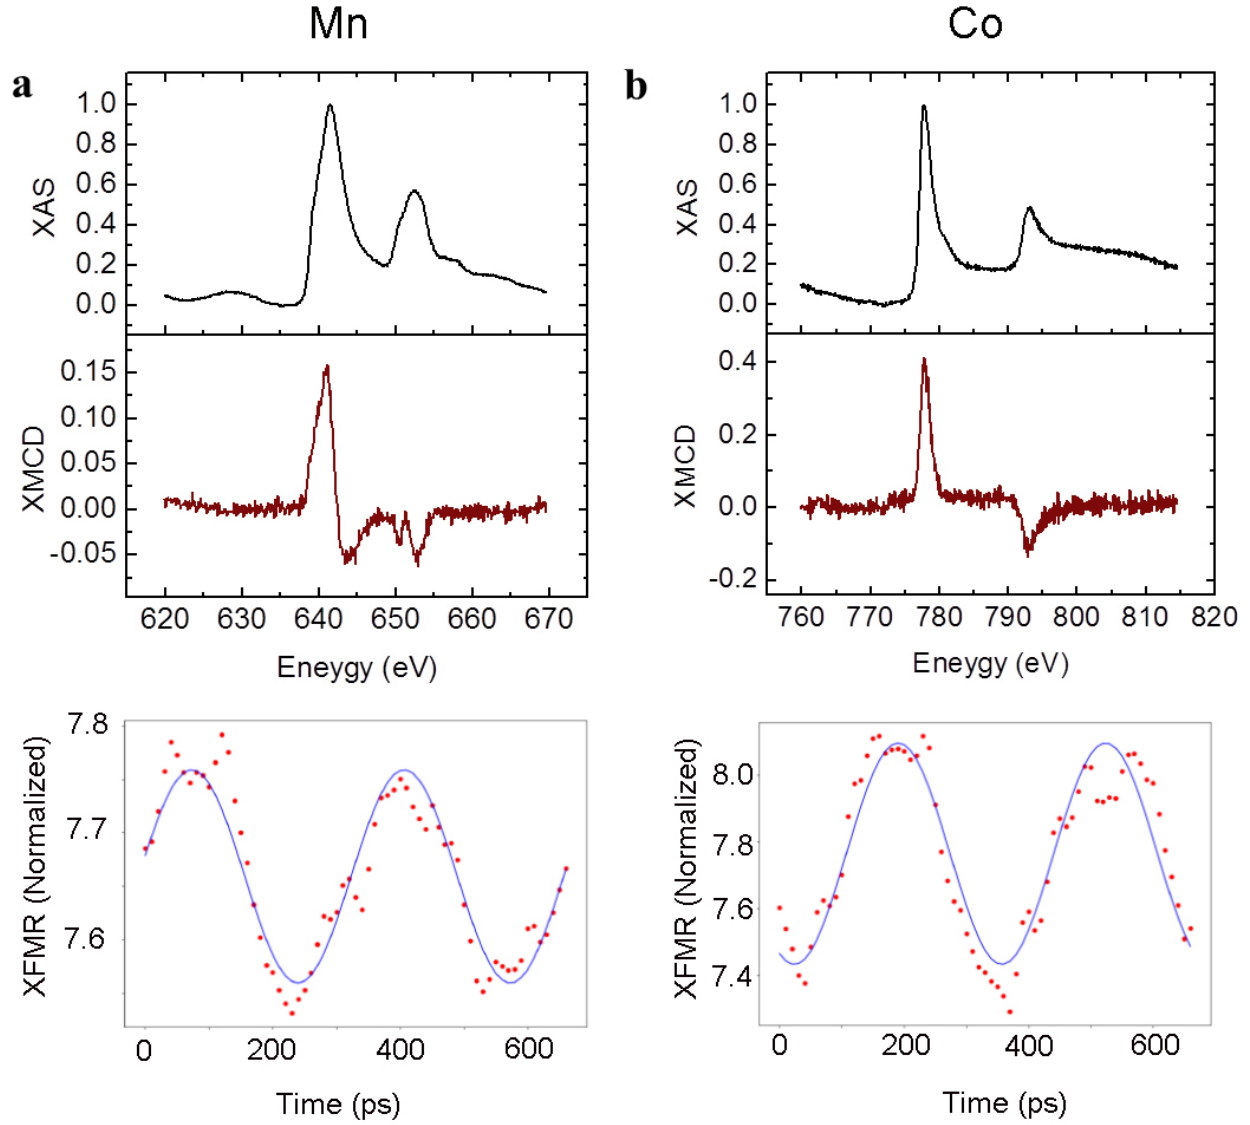

Extended Data Fig. 3. Atomic scale control of interface termination by pulsed laser deposition. **a**, RHEED intensity oscillation of the specularly reflected beam during the growth of SrRuO₃ and La_{0.7}Sr_{0.3}MnO₃ on TiO₂-terminated SrTiO₃ [001] surface. A growth of 2.5 unit-cell of SrRuO₃ on TiO₂ terminated SrTiO₃ substrate is required in order to achieve the SrO terminated substrate, due to the fact that RuO is highly volatile at high temperatures and SrRuO₃ is therefore self-terminated with SrO layer⁶². **b**, A schematic of the resulting La_{0.7}Sr_{0.3}O-FeO₂ interface. **c**, RHEED intensity oscillation of the specular beam during the growth of La_{0.7}Sr_{0.3}MnO₃ by direct on TiO₂-terminated SrTiO₃ [001] surface. **d**, A schematic of the resulting MnO₂-BiO interface.

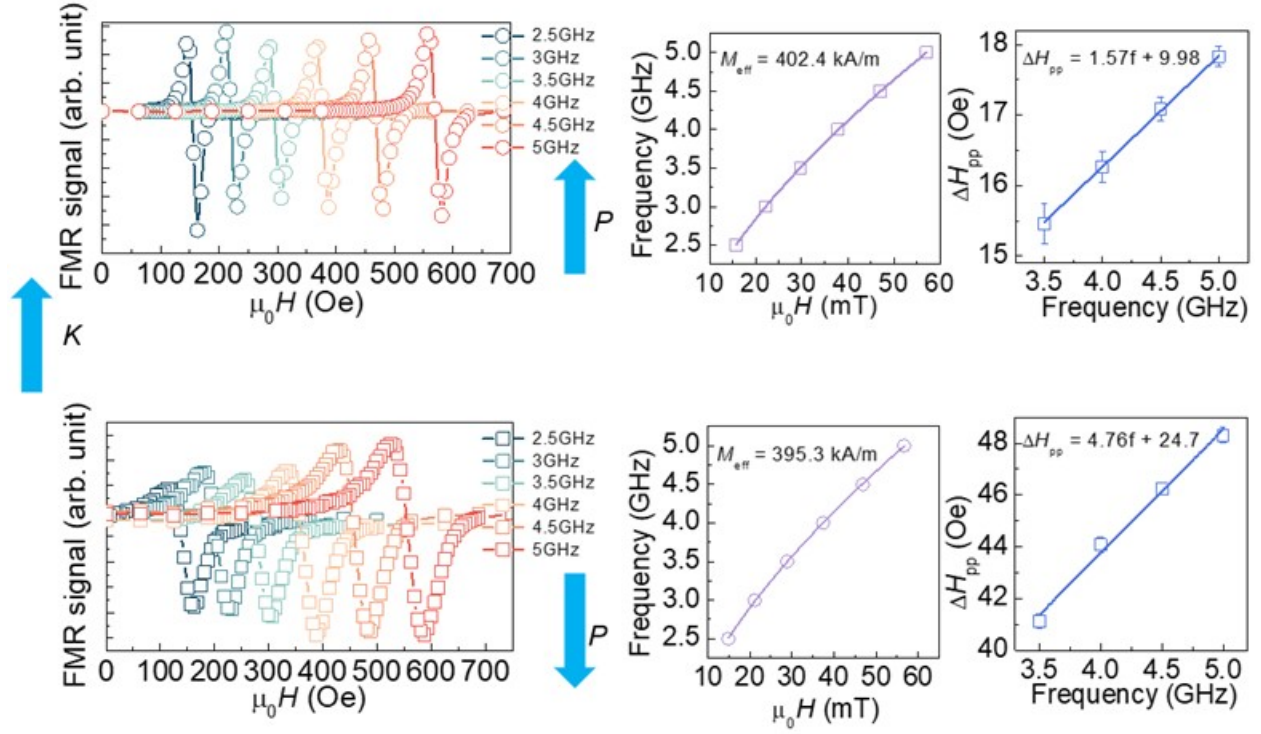

Extended Data Fig. 4. Structure, magnetization, ferroelectric domain structure measurements for $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3/\text{SrIrO}_3$ heterostructure. **a**, HAADF image of $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3/\text{SrIrO}_3$ tri-layer, displaying atomically sharp interfaces and high crystal quality. **b**, HF etched and thermally annealed SrTiO_3 substrate with atomic steps and terraces. **c**, Magnetization vs applied magnetic field (MH) measurement for $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3/\text{SrIrO}_3$, showing a coercivity of ~ 25 Oe and a saturation magnetization ~ 320 emu/cc. **d**, In-plane piezoresponse microscopy (PFM) image of the BiFeO_3 layer. **e**, High resolution XRD 2θ - ω scan of the tri-layer

Extended Data Fig. 5. Ferroelectric control of spin transport enabled by the interface chemistry. **a**, A schematic for $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3$ atomic stacking, where $\text{La}_{0.7}\text{Sr}_{0.3}\text{O}-\text{MnO}_2-\text{BiO}-\text{FeO}_2$ is stacked at the interface. **b**, A schematic for $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3$ atomic stacking, where $\text{MnO}_2-\text{La}_{0.7}\text{Sr}_{0.3}\text{O}-\text{FeO}_2-\text{BiO}$ is stacked at the interface. **c**, Corresponding piezoresponse for $\text{La}_{0.7}\text{Sr}_{0.3}\text{O}-\text{MnO}_2-\text{BiO}-\text{FeO}_2$ stacking ($\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3(12\text{ nm})/\text{BiFeO}_3(50\text{ nm})$), with top and bottom being phase and amplitude respectively. The solid line denotes the shifting of the piezoresponse curves to zero volts, indicating an upward ferroelectric polarization for $\text{La}_{0.7}\text{Sr}_{0.3}\text{O}-\text{MnO}_2-\text{BiO}-\text{FeO}_2$ stacking. **d**, Corresponding piezoresponse for $\text{MnO}_2-\text{La}_{0.7}\text{Sr}_{0.3}\text{O}-\text{FeO}_2-\text{BiO}$ stacking ($\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3(12\text{ nm})/\text{BiFeO}_3(50\text{ nm})$), with the top and bottom being phase and amplitude respectively. The solid line denotes the shifting of the piezoresponse curves to zero volts, indicating a downward ferroelectric polarization for $\text{MnO}_2-\text{La}_{0.7}\text{Sr}_{0.3}\text{O}-\text{FeO}_2-\text{BiO}$ stacking. **e, f**, An artistic illustration for upward and downward ferroelectric polarization. **g**, Spin orbit torque efficiency for BiFeO_3 with different polarization states as a function of BiFeO_3 thicknesses. The red (blue) data points represent the spin-orbit torque efficiency for $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3/\text{SrIrO}_3$, where BiFeO_3 has an upward (downward) polarization.

Extended Data Fig. 6. X-ray magnetic circular dichroism spectra for the X-ray Ferromagnetic resonance measurements in LSMO/BFO/Ti/CoFe Stacks. **a, b,** X-ray absorption spectra (XAS), X-ray magnetic circular dichroism spectra (XMCD), and X-ray ferromagnetic resonance (XFMR) of Mn(a) and Co(b), which correspond to the magnetic element in LSMO and CoFe respectively. The X-FMR measurements confirm the ac spin current transport through BFO.

Extended Data Fig. 7. FMR measurements for LSMO (20 nm)/BFO (10 nm)/SIO (10 nm) samples with different polarizations. **a, b**, FMR spectrum for LSMO/BFO/SIO heterostructures with upward and downward ferroelectric polarizations respectively. Arrow **K** is a representation of spin propagation with respect to the polarization direction for FMR measurements. Resonance fields and frequencies are summarized in **c** and **d** for heterostructures with upward and downward respectively. Effective magnetization 402 kA/m and 395 kA/m are determined with Kittel equation fitting. **e, f**, Peak-to-peak linewidth as a function of frequency is shown for heterostructures with upward and downward polarizations respectively. Effective Gilbert damping constants (α) of 0.00381 and 0.0116 are estimated for systems with upward and downward polarizations respectively

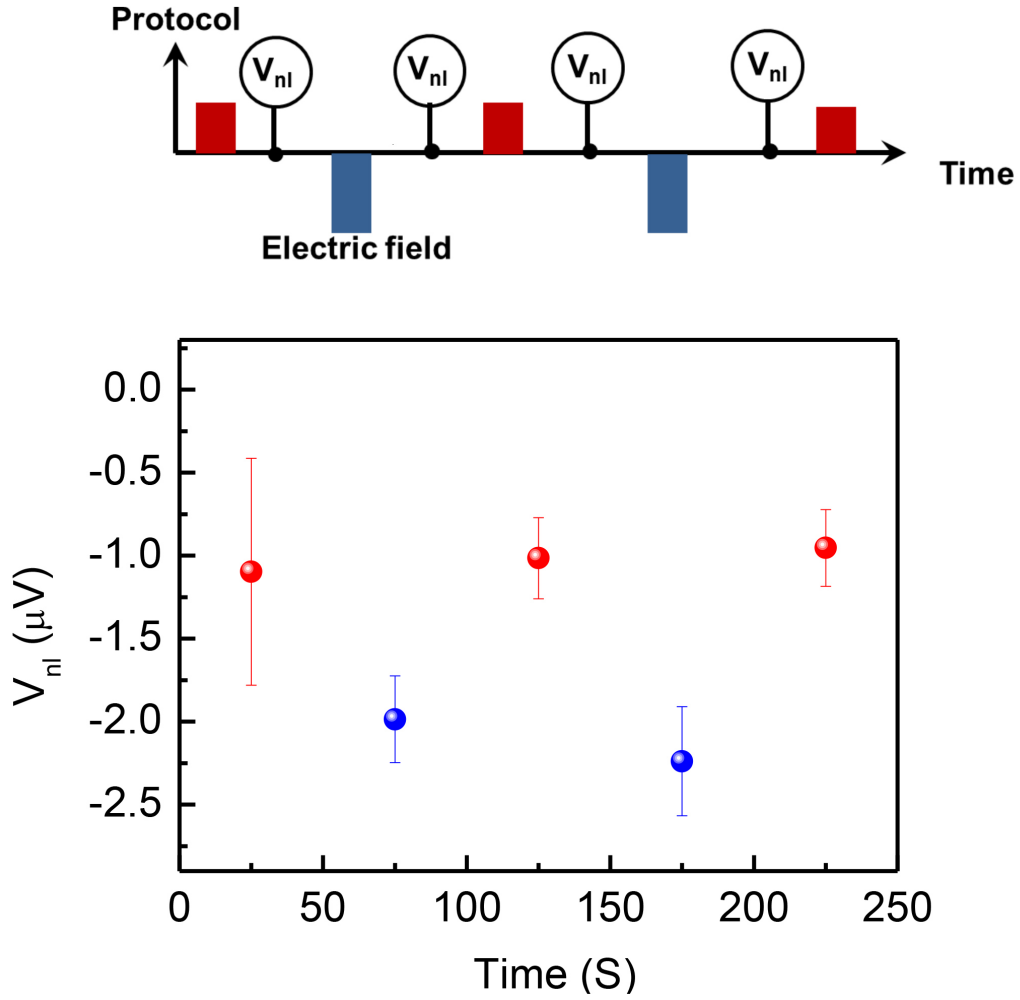

Extended Data Fig. 8. FMR measurements for LSMO (20 nm)/BFO (40 nm) samples with different polarizations. **a, b,** FMR spectrum for LSMO/BFO heterostructures with downward and upward ferroelectric polarizations respectively. Resonance fields and frequencies are summarized in **c** and **d** for heterostructures with downward and upward respectively. Effective magnetization 395 kA/m and 389 kA/m are determined with Kittel equation fitting. **e, f,** Peak-to-peak linewidth as a function of frequency is shown for heterostructures with downward and upward polarizations respectively. Effective Gilbert damping constants of 0.01177 and 0.013335 are deduced for downward and upward polarizations respectively

Extended Data Fig. 9. Exchange bias in BiFeO₃-based heterostructures. MOKE measurements for LSMO (20 nm)/SIO (10 nm) and LSMO (20 nm)/BFO (25 nm)/SIO (10 nm) samples at room temperature.

Extended Data Fig. 10. dc non-local voltage as a function of applied magnetic field at room temperature. The applied dc current is 10 μA .

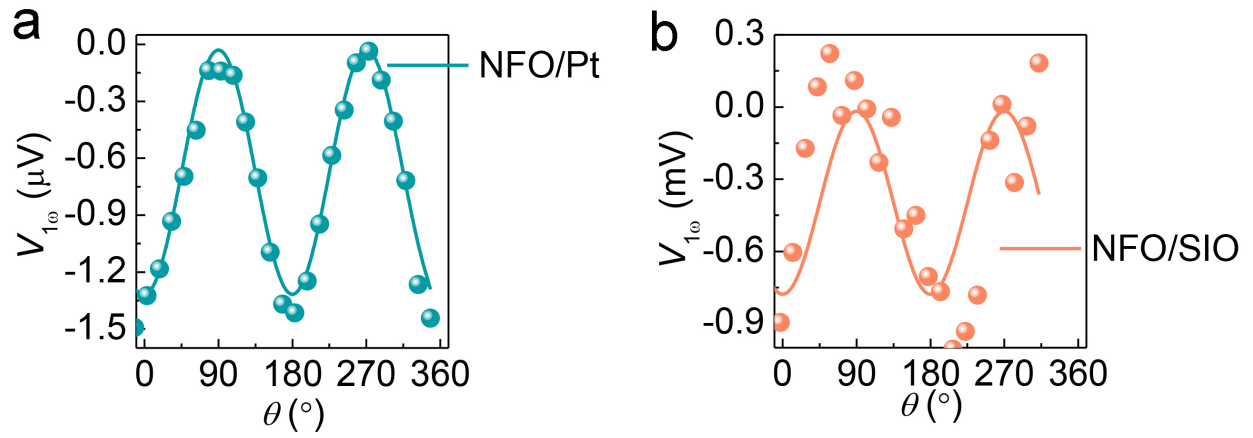

Extended Data Fig. 11. Electric field controlled non-local spin transport measurements with dc current input. A positive electric field of 150 kV/cm and a negative electric field of -300 kV/cm are applied alternately, with dc non-local voltages measured in between the electric fields as shown in the measurement protocol. The corresponding non-local voltage between each electric field is shown below. Each data point is averaged over a time interval of 50 s.

Extended Data Fig. 12. AFM spin current under L switching. Calculated y -component of the total spin current for up (blue) and down (red) polarization orientations. The applied magnetic field \mathbf{H} to generate the excitation is set along $[\bar{1}01]$. The Néel vector in both polar configurations is different indicative of a possible 180° switching scenario of \mathbf{L} . The ratio of the time-integrated dc components is $+0.978$.

Extended Data Fig. 13. AFM and SQUID characterization. **a**, An AFM image for SrIrO₃ (15 nm) grown on YIG/GGG structure. **b**, An AFM image for SrIrO₃ (15 nm) grown on NiFe₂O₄/STO structure. **c**, Magnetization as a function of temperature from 10 – 400 K, with a magnetic field of 1500 Oe applied in the plane. **d**, Magnetization as a function in-plane magnetic field at 300 K.

Extended Data Fig. 14. Non-local control experiments on NiFe_2O_4 (70 nm)/Pt (5 nm) and NiFe_2O_4 (70 nm)/ SrIrO_3 (15 nm). First harmonic voltage signal is displayed in **a** and **b** for NiFe_2O_4 /Pt and NiFe_2O_4 / SrIrO_3 respectively. An ac current with an amplitude of 100 μA and a frequency of 17 Hz was applied in a channel that is separated by 1 μm from the detection channel.
