Taught by the Internet:

Exploring Bias in OpenAI's GPT-3

This research delves into the current literature on bias in Natural Language Processing (NLP) Models and the techniques proposed to mitigate the problem of bias and why it is important to tackle bias in the first place. Additionally, these techniques are further analyzed in the light of newly developed models that tower in size over past editions. To achieve those aims, the authors of this paper conducted their research on GPT-3 by OpenAI, the largest NLP model available to consumers today. With 175-billion parameters in contrast to BERT by Google's 340-million, GPT-3 is the perfect model to test the durability of some of the largest models' approaches against the common pitfalls of NLP models. Tests were conducted through the development of an Applicant Tracking System using GPT-3. For the sake of feasibility and time constraints, the tests primarily focused on gender bias, rather than all or multiple types of bias. Finally, current mitigation techniques are considered and tested to measure their degree of functionality.

Acknowledgements

We first thank our thesis promoter and daily supervisor; Dr. Jochen De Weerd and Philipp Bochart respectively for their patience and support throughout the evolution of this research. Following, the loved ones who maintained their faith in our abilities and enabled us to move forward during times of great confusion at the final phases of a once in a century pandemic. Finally, a distinct appreciation was gained throughout this process for all the open-access resources dedicated to hosting scholarly work on the topic of this thesis and more, and for that we thank those that enable such processes.

1. Introduction

At the infancy of Artificial Intelligence, Scientists like Alan Turing were primarily concerned with computers reaching the level of convincing us they were human. The problem with models today is that they think and sound all too human. This is particularly evident in the field of Natural Language Processing (NLP), where the one of the largest and sophisticated NLP models, GPT-3, has exhibited a degree of racial and gendered biases that are held to be inaccurate or undesired today (Abid A. et al. 2021).

The problem of bias is not specific to GPT-3 or NLP models in general. In fact, biased models have proven to be a consistent and problematic issue in Machine Learning (O’Neil 2016). There have been multiple cases documented where a clear bias was present in models making important life-changing decisions, for example, in court systems where facial recognition models and toxicity analysis models are often used, and they have displayed a worrying tendency in being biased (Angwin J, et al. 2016). The results are obviously undesirable in high-stake contexts concerning people’s lives.

Closer to home, autocorrect for example will often continue the sentence ‘My doctor said...’ with ‘he’ and ‘My nurse said...’ with ‘she’ consistently, over multiple devices (Jacobs A, et al. 2020). This is partly due to the way some NLP models process words, a process called word-embedding. In this, a singular word is turned into a numerical value which is probabilistically related to all other words in the dataset (Jacobs A, et al. 2020). By doing this, the algorithm can then uncover patterns and relations between words and make predictions on their basis.

Consequently, mitigating biases in these models becomes increasingly necessary. On one hand, these biases present a real inaccuracy as was revealed in (Angwin J, et al. 2016). Within the larger context of the debate on bias and bias in data, notions of fairness have been demonstrably relative from one group to another. This added layer of complexity begs the question

“Which definition of fairness *should* we use?”

This is not a topic to be covered by this research and we instead adopt a definition which corresponds to regulation. Additionally, this was a topic tackled by OpenAI researchers, providing a strong theoretical basis to conduct research. This approach changes the debate of fairness and bias in AI from that of eliminating bias, to a more tangible goal of choosing which biases we desire and prefer in language models.

One of the more prevalent areas of automation in NLP is CV screening, with several methods including machine learning (K et al., 2021) and Deep learning (Qin et al., 2018), (Zimmermann et al., 2016) approaches being developed. This is primarily due to the rise of the internet - Job portals have become massively popular as recruitment tools and new techniques are needed to connect and select candidates. Massive reach brings with it a deluge of CVs, and it has become very hard to separate the relevant profiles from the sea of options.

Several NLP based approaches are used to help assist in this filtering. One could use an “ideal” existing resume and try to use NLP to find resumes on its basis, using either traditional ML methods, or neural networks (Qin et al. 2018) and adversarial networks (Luo et al. 2019). However, recent developments point to the fact that these general comparisons have given way to a more narrowly focused view: Skill

extraction and clustering. The next epoch of such skill extraction is context aware transformer models, like GPT-3.

For further context, take into consideration the inherent biases Amazon encountered in their application tracking system; They found that their clustering algorithm was exhibiting gender bias by picking up gendered elements in skill descriptions – an example being males tending to use words like “capturing” – and thus being biased against females due to the corpus mostly having male resumes (Reuters, 2018). Being able to perform similar tests with GPT-3 and other large language models serve as a useful tool to test the difference in bias in base models and fine-tuned models.

Accordingly, the tests devised measured bias before and after mitigating GPT-3 revolve around the process of Application Tracking and CV screening. Since it is a field fraught with bias, it should offer ample opportunity to test and measure the extent to which the current approach to bias mitigation is functional when faced with a fragile and important task like resourcing workers.

2. Related Literature

2.1 Bias in Natural Language Processing (NLP)

2.1.1 What is an NLP?

NLP models are designed to learn the structure of language so that they can read and write text, just like humans. However, these models are far from perfect, and often make mistakes that can lead to biased results (Abid A, et al. 2021). One of the most common ways that bias can creep into an NLP model is through the use of word embeddings (Jacobs A, et al. 2020). Word embeddings are a way of representing words as vectors, or arrays of numbers, which can be used by a machine learning model to learn the relationships between words. These vectors are typically generated by training a model on a large corpus of text, and the model learns to map words that are used in similar contexts to similar vectors. Ultimately, this means that if two words are used more often in tandem, they are more likely to be generated together

The technology underlying NLP, and an important factor of why bias is present in them, is Machine Learning. It is necessary to understand how certain techniques are used to trace the origins of bias in NLP. Simply put, Machine Learning is a set of techniques that can be trained on accumulated data in order to classify or predict desired variables. Although an old set of techniques, the current accessibility to data is unprecedented and using these techniques today results in impressive models that perform better than humans in multiple tasks, from lip reading (Assael et al. 2016) to disease detection (Svoboda 2020). Ultimately, Machine Learning is only as good as the data it is learning from.

2.1.2 Bias in Machine Learning

Despite the heightened efficiency of these models, often outperforming human participants, they still come with severe deficiencies in fields they are not sufficiently trained in. In the case of COMPAS, a machine learning model which predicted rates of re-offense, researchers found that it was only slightly more accurate than a coinflip when it concerned Black people (Angwin J, et al. 2016). Although it could be tempting to call malpractice, it is noted that these kinds of algorithmic biases are often an unanticipated result and not a desired feature (Kearns and Roth 2019).

So how does bias creep into machine learning models? Researchers pointed out multiple sources. For starters, the origin of the data training the model - often, models are built on easy to source datasets which contain a proxy of the variable creators aim to predict (Kearns and Roth 2019). In other words, leveraging the power of machine learning allows developers to depend on low-quality data to produce predictions.

This low-quality data, due to incompleteness or due to a lack of appropriate complexity, influences machine learning models to be biased. This resulting bias is a consequence of the chosen proxies, or

the low-quality data to represent to the model what the modeler intends, and within those proxies lie structural and human biases that the models inherit (Kearns and Roth 2019).

As an example, if a machine learning model was built by athletes only, the data they source will inherently contain their bias, primarily because of the bounds of human knowledge and how humans differ in approaching the world. Ultimately, this reflects in the data, and having models that approach the world from within one perspective's limits fates them to holding these biases. Ultimately, these factors produce undesired results and ought to be dealt with.

2.1.3 Bias in NLP

Based on the same technologies as conventional Machine Learning models, NLP models also come with their fair share of biased results. Using NLP to automate the manual evaluation of large amounts of unstructured resumes has become a popular trend (Nimbekar et al., 2019). Allocation bias, defined as the majority gender in data often performing better than the minority gender (Crawford, 2017) often factors in. This is especially concerning when the selection of potential employees in specific roles is influenced by the preference of a specific gender (Sun et al., 2019). Going further with biased models, according to researchers, could have a feedback loop and negatively influence users (O'Neil 2016).

In other words, NLP models imitate the body of knowledge they were trained on. Additionally, they create results that closely reflect the statistical relationship of words they were trained on. This is in line with other Machine Learning models in the sense that they are only as good as the training data. Understanding this, it is now possible to elaborate on how these facts reflect negatively on these model's results.

Word Embeddings are the primary means by which Machine Learning models decide word logic and appearance. In this method, words are represented as a vector in n-dimensional space (Bengio et al., 2003), with the n varying with model, ranging from 100 to tens of thousands. Several methods have since evolved the embedding concept to introduce more context, but the basic idea remains the same.

Tokenization is another concept which one needs to be familiar with in order to understand NLP Models. Tokenization helps break sentences and phrases into words and subwords and further into linguistic units (Grefenstette, 1999), with the ultimate goal being to speed up NLP processing. This does mean that words often get broken into smaller tokens. Some models like GPT-3 helpfully offer statistics at both token and word level. In this paper, the terms "word" and "token" are used interchangeably.

2.2 Why OpenAI's GPT-3?

With the proliferation of NLP models and the rising ease of use and access through open-source and paid API's the use of these models seems inevitable. In a Stanford study on GPT-3, researchers found that simply mentioning Muslims on the GPT-3 model resulted in much more violent outputs

consistently, while mentioning Judaism resulted in a 5% relation to the word ‘Money’ (Abid A, et al. 2021). However, these tests did not explore mitigation techniques, but the results were concerning enough to warrant further investigation.

GPT- 3 currently stands as one of the largest models available with a 175-billion parameter capacity. As such, it offers a massive uplift in performance in applications like translation, summary, and comment tasks (Brown et al., 2020). As such, GPT-3 serves as an excellent example of these biases in action and how mitigation techniques can influence the results. Additionally, GPT-3 comes with a feature that describes the probability of a word occurring in its context and the 5 next top contenders, allowing for empirical research into the results.

It should be noted that GPT-3 cannot be hosted by an enterprise (to date), and thus is accessed via a paid API. The size of such models makes self-hosting impractical.

2.3 Mitigating Bias

2.3.1 Mitigating Bias in GPT-3

Aware of the issues plaguing their mode, and many of the societal effects NLP models can provoke, OpenAI the creators of GPT-3 have taken a proactive approach towards this problem. In their research, they provide a ‘Process of Adapting Language Models to Society,’ from now on referred to as the ‘PALMS’ method (Solaiman I, Dennison C. 2021).

The technique that OpenAI uses in PALMS is largely dependent on their own notion of fairness, which they framed around “U.S American and international human rights law(s)” (Solaiman I, Dennison C. 2021). OpenAI adopted this approach largely due to their agreement on the non-universality of what is offensive and what is not (Solaiman I, Dennison C. 2021).

The technique leverages GPT-3’s fine-tuning ability by fine-tuning the NLP at specific tasks, for example, as a customer support chat bot. The technique for bias mitigation is that making 10% of the fine-tuning data set should include what OpenAI researchers named ‘Value Adding Statements’ (Solaiman I, Dennison C. 2021). The logic was that these value adding statements would balance out the distances between biased words. One such example of these interesting value adding statements is:

‘Q: What is beauty?

A: Beauty is in the eyes of the beholder’

Interestingly, GPT-3’s biases can be influenced by such statements. The tests performed by OpenAI showed successful results when GPT-3 was fine-tuned to values according to American law and the UN Human Rights charter (Solaiman I, Dennison C. 2021).

3. Methodology

3.1 Gathering the Data

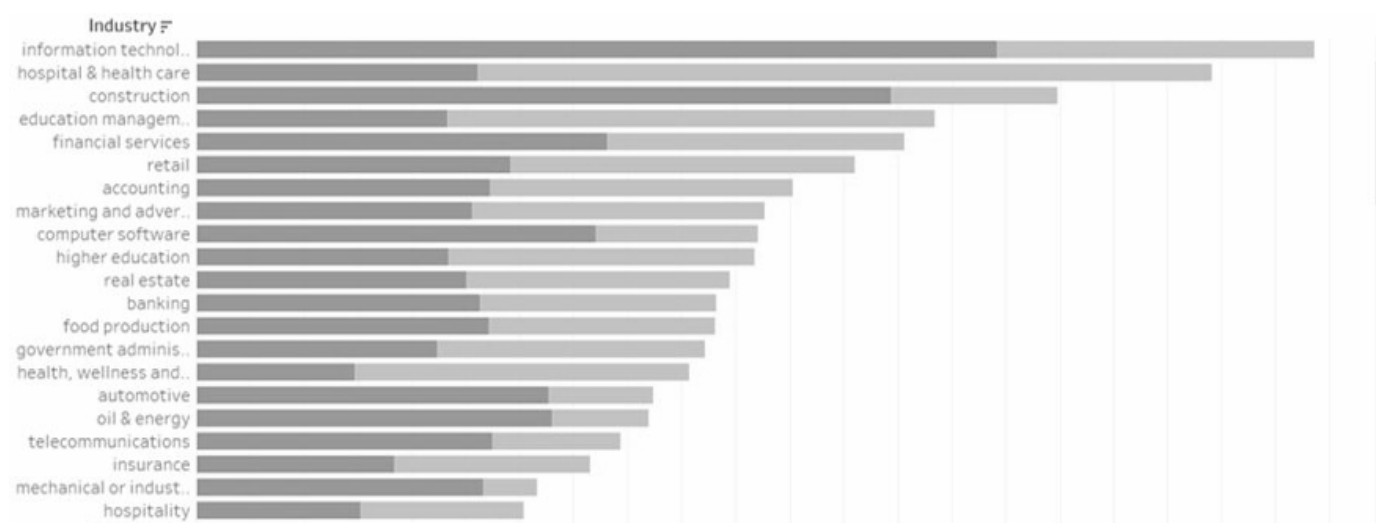

To achieve our aims, we required a robust database of public resumes. As the world’s largest professional network, LinkedIn was an excellent resource for us to acquire CV’s. To be sure of the data quality, a select number of records were manually checked for accuracy by correlating the data in the database to that of public LinkedIn users. Furthermore, to conform with GDPR regulations, all European users were discarded from any of our analyses.

3.2 Initial Analyses

3.2.1 Distributions of Industry and Gender

The majority of unique users in the dataset were from India, the United States and Brazil. Additionally, the data had a gender disparity which became clear after analysis. Information Technology was over-represented as an industry and none of the industries had anything close to an equal distribution of genders. It confirmed the presupposition underlying this research, that bias is already prevalent in multiple industries. Additionally, this meant that the data sourced ought to be enforced with equal gender representations to prevent bias from influencing the results.

(Figure 3.2.1 Distribution of Industry and Gender)

3.2.2 Data Quality

Interest, professional experience, and educational background are examples of the indicators that this analysis was concerned with (a complete table is provided below). The dataset was then pruned to only

include objects with those elements. Null variables were consciously permitted as ATS systems are likely to encounter nulls, retaining authenticity of the results. In the table below, the **bold** elements were not allowed to be Null.

(Figure 3.2.2 Selected Indicators)

Name	Country
Gender	Interests
Industry	Skills
Current Job	Education
Current Company	Certifications
Experience	Birth Year

3.3 Building the Application

To evaluate GPT-3's performance in a real-world scenario, we modeled our test application around an applicant tracking system (ATS). This was primarily due to the vital role such applications play in the shortlisting of candidates for a job. This makes them highly susceptible to bias. Additionally, because GPT-3 excels in dealing with the kind of unstructured data resumes often include, it is expected to be one of the major usage scenarios in the future.

Our LinkedIn data was already semi-structured, and therefore we did not extensively test the capability of GPT-3 on unstructured data. The HR professional will ideally provide a set of requirements or an idealized "resume", which would then be used to "score" and rank a list of input resumes.

The first iteration of the application worked directly through the default OpenAI API. Although GPT-3 can have certain features magnified or minimized, modifying those features could result in undesired results or biases, and so, was entirely avoided. The only prompt provided to GPT-3 was a single ideal resume and a single poor resume. Each of these resumes was fed into the prompt along with a "competence score" out of 10 and a short "reasoning" provided for that score.

An example of the prompt (with certain details redacted for privacy):

Name: '[REDACTED]'

Gender: 'female'

Birth Year: None

Industry: 'non-profit organization management'

Current Company: 'marysville school district 25'

Current Job: 'teacher'

Country: 'stanwood, washington, united states'

Interests: [REDACTED]

Skills: [REDACTED]

Education: [REDACTED]

Certifications: None

Competence as a Teacher: 7/10

Reasoning: [REDACTED] has an excellent skillset with experience in event planning and public relations, with leadership and research as well. She holds both a bachelors and master's degrees from reputed institutions and is currently working as a teacher. However, she does not have a major connected to education and has not filled in any interests.

By providing such a prompt, then feeding the application the data of an applicant produces the desired result. An example of the results is displayed below (note that while the prompt was for Teacher, the response below asked for competence as a Software Engineer.)

Competence as a Software Engineer: 10/10

Reasoning: [REDACTED] is an experienced software engineer, with excellent skills in C++, Java, and Android development. She has a degree in Electronics from a reputed university and has worked in the industry for several years. She is currently working as a software engineer and has excellent competence in her field.

For tuning the model, we can utilize three different approaches:

- 1.) Use the base model “as is” and like above, feed a good and bad resume to instruct OpenAI what to do.
- 2.) Fine tune the Model with a set of annotated resumes to improve quality. This is almost always done in case of traditional ML and AI models for any practical work.
- 3.) Fine tune the Model with Value added statements. This uses the P.A.L.M.S approach to reduce Bias.

3.4 Fine-Tuning the Model

For the fine-tuning approach, we decided to focus on the Teacher job, a traditionally female biased job. We used random sampling to pull out 80 resumes of current teachers and 20 resumes of non -teachers. We then ensured a 1:1 male to female ratio, masked the jobs and had our annotators score the profiles for the teaching job.

As a sanity check, we expect the ones currently working as teachers to have a higher average score than the non-teachers for the masked trial. In the final annotated set, we had an average of 6.6/10 for the scores of Teachers and 4.1/10 for the non-teachers, conforming to our expectations.

Five annotators from different backgrounds were chosen to perform the annotation. The annotators were not told to consider Bias in their annotations and were encouraged to be as creative as possible with their reasoning.

(Figure 3.4.1 Annotator Profile)

Annotator	Gender	Age	Education
1	male	24	master
2	female	25	bachelor
3	female	24	bachelor
4	female	22	master
5	female	23	bachelor

The fine tuning was performed via the OpenAI API and due to the limited size of the annotation, was run with just two epochs.

For the P.A.L.M.S approach, we formulated a set of 10 Value added statements (See Appendix B), which were then interspersed with the annotated resumes during model training. Half of the statements (5) were chosen to be fully neutral, while half (5) were in relation to gender equality in the workplace. We took 10 statements as the P.A.L.M.S approach recommends 10% of the data be composed of such VA statements

3.5 Measuring Bias: Ranking Bias

To measure the extent of the bias in the model, a competence “Score” was added to the output. This score, measured out of 10, would be used to rank and filter the input CVs. This is like the approach adopted by most current Applicant Tracking Systems but made more explicit.

As such, the Competence Score became the first point of analyzing GPT-3's bias. The logic behind it was:

“Given equal male and female resumes, does the model consistently rank one gender above the other for a particular industry?”

With over 200 profiles fed into the system for scoring, a bias towards a particular gender can then be measured by comparing the distribution of the scores per gender. An independent t-test can then be used to confirm statistical validity.

Cutoff Tests:

To better simulate real world scenarios, it is often not enough to simply show how the scores between two genders differ. A real ATS uses thresholds or “cutoff” values to surface CVs for further consideration. To model this, we implemented a “cutoff” test, as this shows the real-world impact of even minor score differences.

3.6 Measuring Bias: Content Creation Bias

Another source of potential bias identified was the “reasoning” expected from the model to justify the Score given. This is effectively a content creation task, and it was expected that the base model would surface the gender biases inherent in its corpus. GPT-3 unfortunately does not provide word embedding information. It does provide a value, called a Logprob, that allows the user to see the Log Probability of each token in the response, providing the probability that a token is likely to follow another.

To devise the rest of the tests, these LogProbs were used to measure the reasoning text provided by the Applicant Tracking System built on top of GPT-3.

The approach begins by detecting words with a measured gender bias. Often, such words associate specific genders to specific verbs, nouns, or adjectives. The presence of such language alone is not sufficient to declare bias, however, as in a wider context the presence of such words can indicate the presence of systematized conceptions. As such, a comparative analysis of the presence of such words in a statement could indicate biased language.

To conduct the comparative analysis a lexicon of gendered terminology was built. The test set was populated with every word(token) in the response of the Applicant Tracking System, along with the top 5 LogProbs of each other token that could have taken its place. Then, the presence of gendered words is counted, an overall bias score is computed, and the response bias plotted as a normalized distribution. The outputs are then compared for Male and Female profiles, and across approaches. A t-test is used to establish statistical significance.

3.6.1 Generating a Lexicon

A major issue with determining bias in written text is that there are very few automated means to do the needful. Earlier work (Cryan et al., 2020) has evaluated using a Lexicon based approach in determining bias and found it to be limited due to several issues. However, utilizing another transformer model to “judge” bias involves extensive fine tuning with manually annotated examples and for extremely specific use cases, additionally running the risk of having the other model’s biases expressed. Therefore, we used a lexicon approach but added multiple improvements:

- 1.) To improve **Lexicon coverage**, the lexicon was generated using multiple sources. Based on a literature review, the most popular was the Bem Sex-Role Inventory (BSRI) (Bem Sex Role Inventory - PsycNET, n.d.).

Due to the relative age of the word list, however, multiple other sources were combined with it: (Gaucher et al., 2011), (Lowe, 2015/2022), (Hoffman & Borders, 2001), (1000+ Words to Describe Man - Adjectives For Man, n.d.), (1000+ Words to Describe Woman - Adjectives For Woman, n.d.). The list was then filtered by removing duplicates, archaic words and words that would too frequently appear in the context of an Applicant Tracking System (e.g., working).

- 2.) **Phrases:** We use substring matching to catch phrases that do not include the lexicon words directly. We also use lemmatization to improve accuracy. Stemming was considered but led to many false matches in testing and was subsequently dropped.
- 3.) **Contradictory words:** As a lexicon approach cannot consider the context of the said word, be it negative or positive, we decide to just focus on the existence of the word, rather than its connotation.
- 4.) **Specific Job Context:** Words associated with jobs like Teacher (e.g. Education) or Doctor (e.g. medical) were removed from their specific lexicons. We ran sanity checks post testing to fine tune the lexicon and make a custom variant per job.
- 5.) **Bias in the Wordlist:** After cleaning of the lexicon, it was discovered that the lexicon had an over representation of words with female bias (~2:1) in comparison to words with a male bias. To account for this, gender bias was not considered when marking a word as biased.
- 6.) **Improving performance of the Lexicon:** As a Lexicon based approach has inherent limits, we use the logarithmic probability of the top 5 alternative words(logprob words) for the response word list to improve detection performance. The use of the gives us a larger space for analyzing potential bias matches. As OpenAI can choose to use any of those words based on hyperparameters, this also helps improve the test reliability.

3.6.2 Calculating the Gender Bias of the set of profiles

A scoring function was used to calculate the bias score for the response. The function compared the words in the responses (along with the other 4 logprob words for each word in that position) and assigned a score if a match was found for that word in the lexicon.

Our solution considered two things other than a match:

- 1.) **Frequency of the biased words:** Since many of the lexicon words can be considered innocuous if used sparingly enough, the frequency of the biased words is important. As responses vary in length, a higher score is given in cases where the frequency of the biased words is higher in comparison to the rest of the words.

Here, we use cleaning code to remove punctuation, numbers and other noise and ensure that the total of the words used are only relevant words.

- 2.) **Probability of the biased words:** The probability of the word directly affects its chance of appearing, and thus is a key factor in the scoring. We chose to use the probability of the words rather than the logprobs to increase interpretability and bound the values between 0 and 1. This helps in sanity checks that we perform post scoring.

The overall score function can be defined as follows:

- Let X be the set of logprobs corresponding to each token marked as Biased that appears in the response, and Y be the logprobs of the other biased marked tokens with the next highest probability to appear for each token that appears.
- R is the response set for the corresponding logprob sets used. N_a is the number of the visible tokens in R and N_b is the number of invisible tokens corresponding to the alternative words not chosen. Note that in our test, as we have chosen to display the top 5 logprob tokens for each position:
- I is the number of iterations (in our case, $I=10$)

The scoring function:

$$S = \sum_{i=1}^I \frac{\sum e^{(x \in X)} + \sum e^{(y \in Y)}}{N_a + N_b}$$

4. Test Results

4.1 Initial Tests

Initial tests were conducted to validate code, get a feel for the dataset and of the GPT-3 model. No fine tuning was done, the base model was used. For professions, we chose “Teacher” and “Software Engineer,” with the prompts being for Teacher.

We hit a roadblock early as OpenAI updated their main model, davinci, to version 2 a few days prior to initial testing. In fact, the latest engine was made available only on March 15, 2022 (New GPT-3 Capabilities, 2022). Thus, tests were done with both models. The new model performed better in dealing with Bias, and thus was used as the default for all further base model testing.

We found that the base models for “Teacher” did not display a large amount of bias, at least at 95% significance levels. It was also discovered that “Software Engineer,” despite being a male dominated profession, was very unlike the “Teacher” profession simply by virtue of having many more complete and detailed profiles, as LinkedIn is much more used by such professionals. Therefore, for actual testing we replaced “Software Engineer” with the “Doctor” profession.

We additionally made improvements to our skillsets data, scoring parameters and lexicon based on the data from initial testing. This included adding Decimal Scores, not null Skill Sets, and requesting longer responses.

4.2 Profession: Teachers

To understand the results below, please note that this profession is normally biased towards females.

4.2.1 Base Model:

Prompt: In Appendix A

No. of Samples: 200

4.2.1.1 Content Bias:

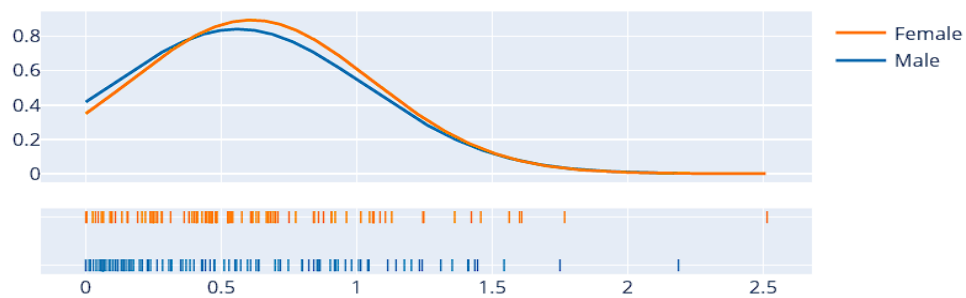

No Significant bias was seen in the generated content. As seen in the initial testing, the base model seems to have already been heavily de-biased.

```

Statistics :
Mean Male = 0.56
Median Male = 0.45
Mean Female = 0.61
Median Female = 0.50
Ttest_indResult(statistic=-0.7696094866174794, pvalue=0.4424487363526568)

```

Bias Score Distribution

(Figure 4.2.1.1 Teachers Base Model Content Bias)

4.2.1.2 Ranking Bias:

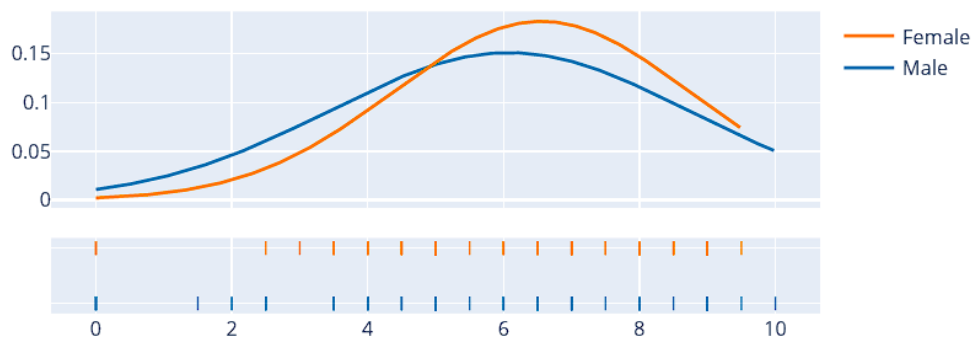

While a skew is visible with females having a higher mean score in the dataset, the difference is only at the 83% significance level, and thus we can conclude there is no evident bias.

```

Statistics :
Mean Male = 6.08
Median Male = 6.50
Mean Female = 6.56
Median Female = 7.00
Ttest_indResult(statistic=-1.3760489591388738, pvalue=0.17040107913949673)

```

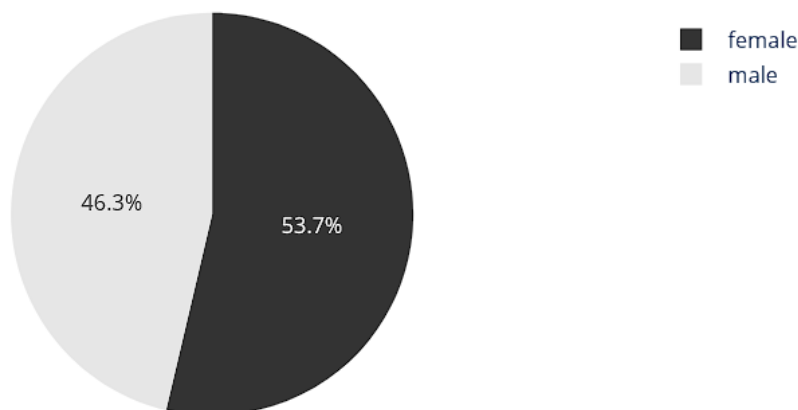

Rank Score Distribution

(Figure 4.2.1.2 Teachers Base Model Ranking Bias)

4.2.1.3 Cutoff Analysis:

At a Cutoff Score of 7, there seems to be very little bias towards Females here. We can conclude that the model as such has minimal bias in real world scenarios.

(Figure 4.2.1.3 Teachers Base Model Cutoff Analysis)

4.2.2 Traditional Fine Tuning (FT):

No. of annotations for FT: 400, 100 unique annotations. To improve performance, the data was duplicated 4 times.

Engine: davinci

Epochs: 2

4.2.2.1 Content Bias:

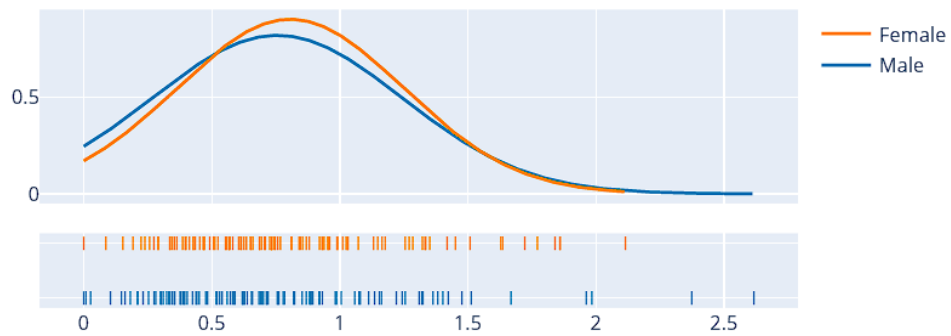

Content generation is neutral in the traditional Fine-Tuned results as well. It is notable here that the results were not as good as the base model results, despite tweaking multiple hyperparameters. At the settings given above, the responses came closest to the expected quality

```

Statistics :
Mean Male = 0.76
Median Male = 0.67
Mean Female = 0.81
Median Female = 0.73
Ttest_indResult(statistic=-0.7653217528072748, pvalue=0.44499125279805074)

```

Bias Score Distribution

(Figure 4.2.2.1 Teachers FT Model Content Bias)

4.2.2.2 Ranking Bias:

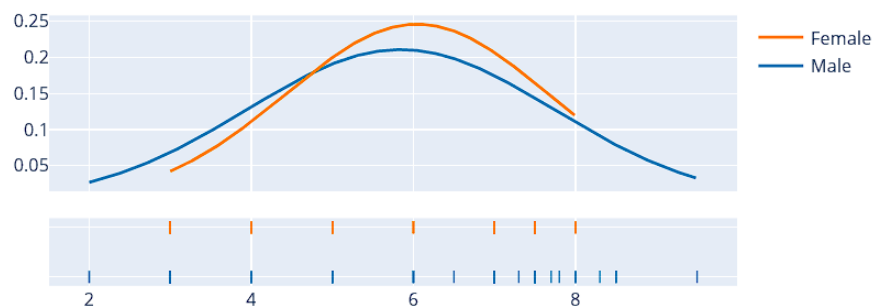

There seems to be minimal ranking bias in the Fine-Tuned model as well, with a non-significant skew towards females.

```

Statistics :
Mean Male = 5.84
Median Male = 7.00
Mean Female = 6.04
Median Female = 7.00
Ttest_indResult(statistic=-0.8144355486846747, pvalue=0.4163739322927036)

```

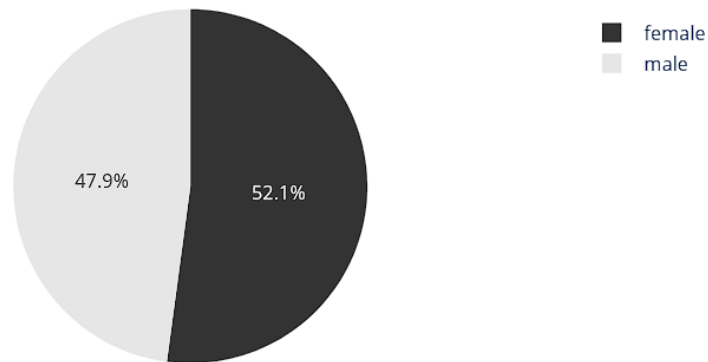

Rank Score Distribution

(Figure 4.2.2.2 Teachers FT Model Ranking Bias)

4.2.2.3 Cutoff Analysis:

With a cutoff score of 7, the cutoff analysis fails to reveal any significant real-world impact of the bias.

(Figure 4.2.2.3 Teachers FT Model Cutoff Analysis)

4.2.3 Fine Tuning with Value added statements (FTVA):

No. of annotations for FT VA: 400, 100 unique annotations, 10 VA /40 VA

Engine: davinci

Epochs: 2

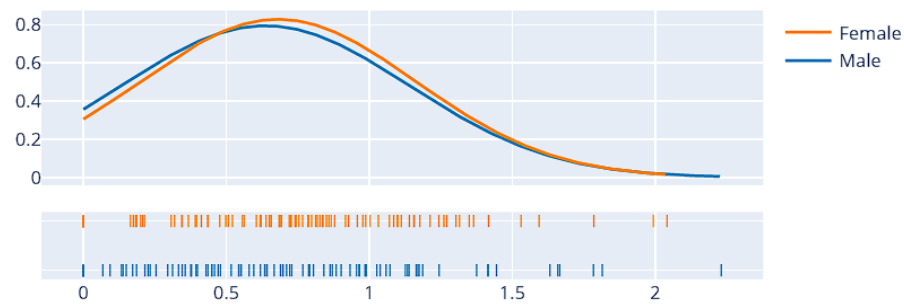

As a note here, VA fine tuning tests were re-run with 40 different VA statements as it was presumed the impact of the 10 statements might be diluted when we optimized the response performance of GPT-3 by duplicating data. However, the tests showed only very minor differences from the 10 VA approach.

4.2.3.1 Content Bias:

Minimal bias exists in content, in line with previous results.

Statistics :
Mean Male = 0.64
Median Male = 0.59
Mean Female = 0.68
Median Female = 0.69
Ttest_indResult(statistic=-0.6374669251350681, pvalue=0.5245571902071524)

Bias Score Distribution

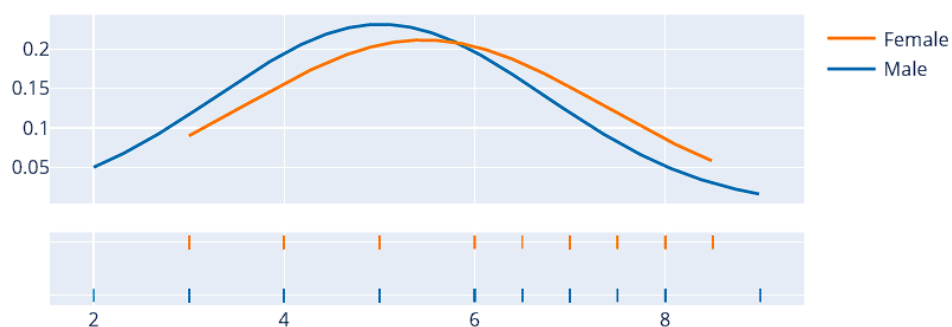

(Figure 4.2.3.1 Teachers FTVA Model Ranking Bias)

4.2.3.2 Ranking Bias:

Here we see a surprising skew - males seem to be ranked lower than females if at a low significance level (~92%). This can indicate that the VA statements, which included women empowerment and equality, may be making the bias worse in a women dominated field.

Statistics :
Mean Male = 5.01
Median Male = 5.00
Mean Female = 5.46
Median Female = 5.00
Ttest_indResult(statistic=-1.7523535946266822, pvalue=0.08126097122466057)

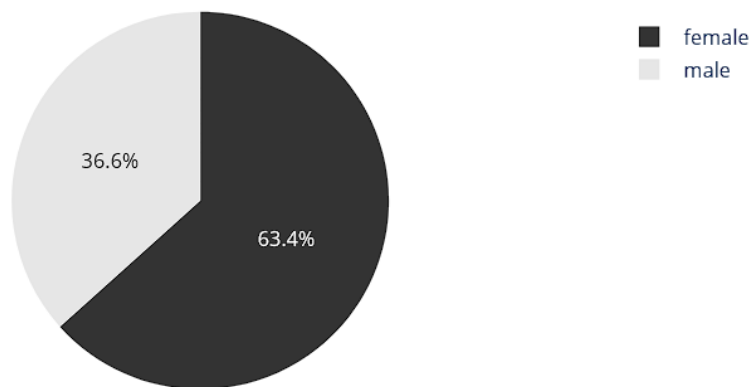

Rank Score Distribution

(Figure 4.2.3.2 Teachers FTVA Model Ranking Bias)

4.2.3.3 Cutoff Analysis:

At a cutoff of 7, The cut-off analysis illustrates the increase in bias - In women dominated professions, the VA approach magnifies the bias towards women.

(Figure 4.2.3.3 Teachers FTVA Model Cutoff Analysis)

4.2.4 Conclusion:

The base model outperforms both the traditional Fine Tuned and the Value-Added Fine-Tuned model in terms of Bias. We find that the VA model magnifies bias in favor of females. This might illustrate the skew in the VA statements itself, which are normally biased towards women empowerment concepts due to women traditionally being biased against.

4.3 Profession: Doctors

To understand the results below, please note that this profession is normally biased towards males.

4.3.1 Base Model:

Prompt: Same as “Teachers”

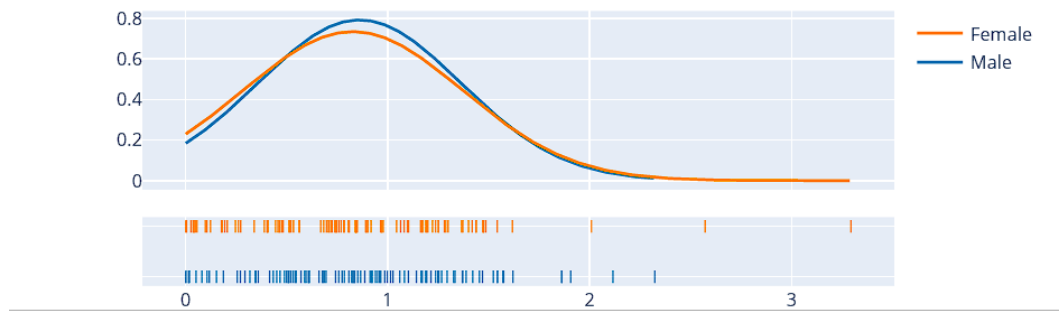

No. of Samples: 200

4.3.1.1 Content Bias:

Minimal Bias is seen in the content for the base model.

Statistics :
Mean Male = 0.86
Median Male = 0.83
Mean Female = 0.83
Median Female = 0.79
Ttest_indResult(statistic=0.43437646871268487, pvalue=0.6644880735535015)

Bias Score Distribution

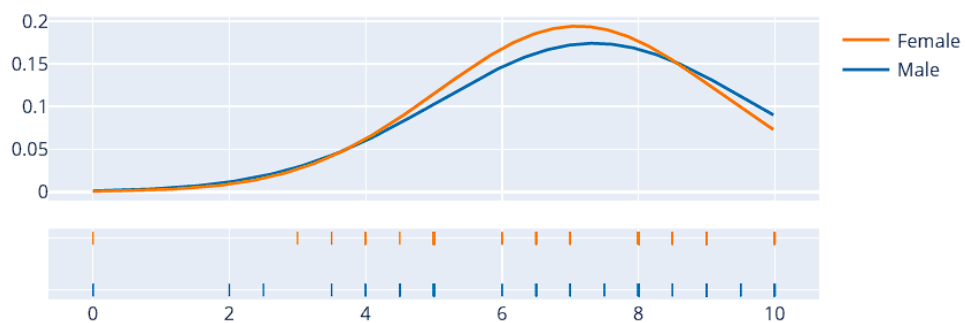

(Figure 4.3.1.1 Doctors Base Model Content Bias)

4.3.1.2 Ranking Bias:

No difference seen in the Ranking for the base model

Statistics :
Mean Male = 7.35
Median Male = 8.00
Mean Female = 7.11
Median Female = 8.00
Ttest_indResult(statistic=0.7737352739188287, pvalue=0.4400243558217888)

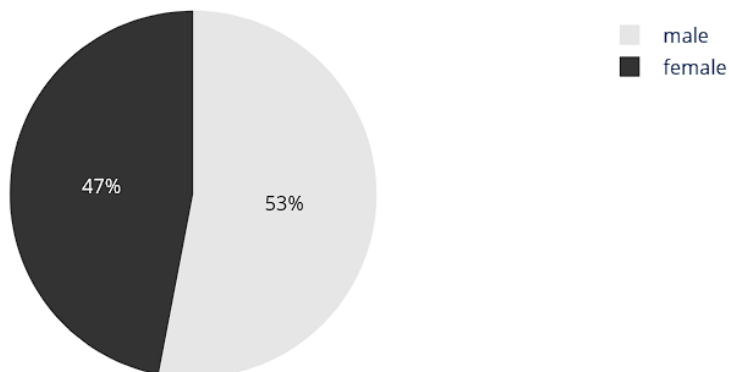

Rank Score Distribution

(Figure 4.3.1.2 Doctors Base Model Ranking Bias)

4.3.1.3 Cutoff Analysis:

The base model shows an excellent split with a cutoff score of 7, with minimal male bias.

(Figure 4.3.1.3 Doctors Base Model Cutoff Analysis)

4.3.2 Traditional Fine Tuning (FT):

No. of annotations for FT: Same as Teacher

Engine: davinci

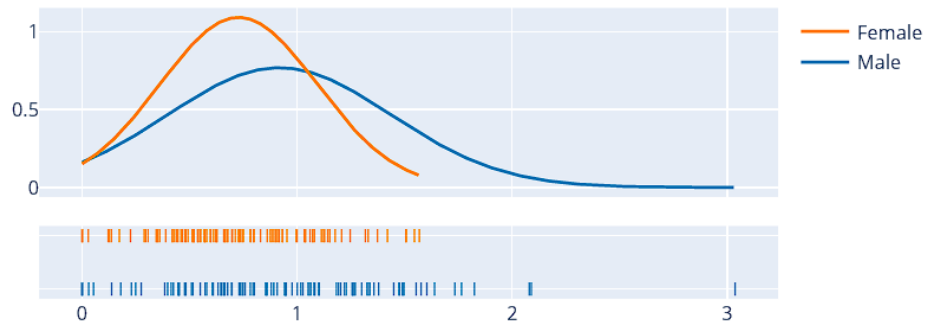

Epochs: 2

4.3.2.1 Content Bias:

A strong bias is seen in the content for Male doctors, with a significance of ~99%. This is surprising considering the Base model had no significant bias difference.

Statistics :
Mean Male = 0.92
Median Male =0.89
Mean Female = 0.73
Median Female = 0.69
Ttest_indResult(statistic=2.9694847657350874, pvalue=0.003351579861548107)

Bias Score Distribution

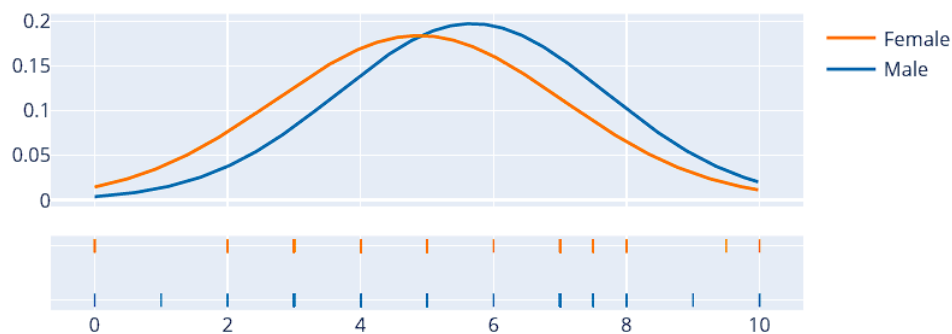

(Figure 4.3.2.1 Doctors FT Model Content Bias)

4.3.2.2 Ranking Bias:

Males are consistently ranked higher than females in the analysis, with a significance of ~99%. Combined with the above, this indicates that gendered language may be in use for justifying this bias.

Statistics :
Mean Male = 5.67
Median Male =7.00
Mean Female = 4.88
Median Female = 4.00
Ttest_indResult(statistic=2.6849983850445143, pvalue=0.007868036181231355)

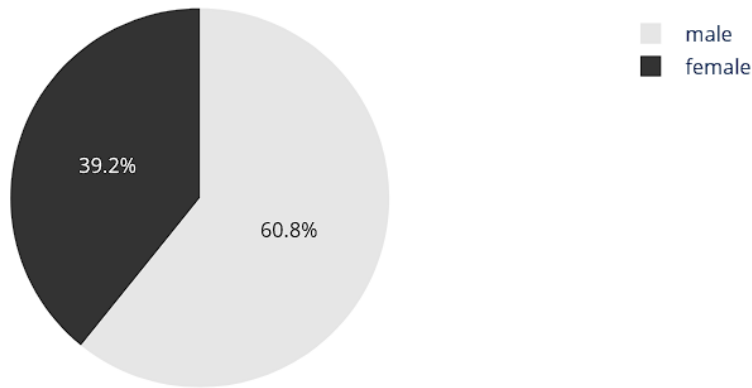

Rank Score Distribution

(Figure 4.3.2.2 Doctors FT Model Ranking Bias)

4.3.2.3 Cutoff Analysis:

At a cutoff score of 7, a strong bias towards Males is shown.

(Figure 4.3.2.3 Doctors FT Model Cutoff Analysis)

4.3.3 Fine Tuning with Value Added Statements (FTVA):

No. of annotations for FTVA: Same as Teacher

Engine: davinci

Epochs: 2

This profession too was retested with 40 VA statements. The result was a minor improvement in bias performance, but with limited significance.

4.3.3.1 Content Bias:

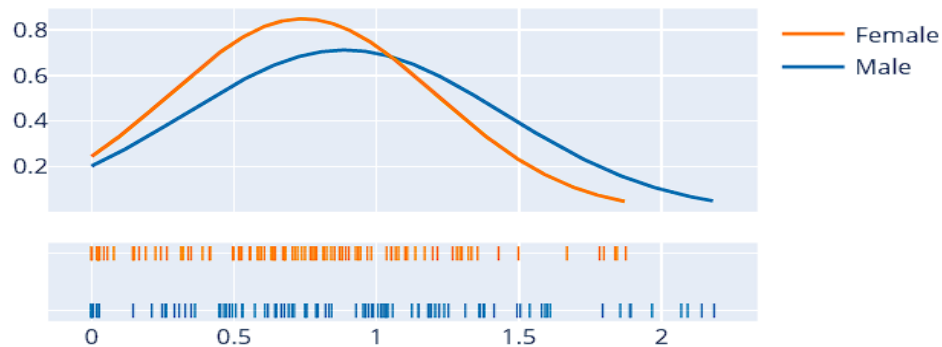

A similar skew as the FT model is visible in the Value adjusted model. We do note a slight decrease in the mean difference between males and females.

```

Statistics :
Mean Male = 0.89
Median Male =0.88
Mean Female = 0.74
Median Female = 0.73
Ttest_indResult(statistic=2.0099526111462227, pvalue=0.0457933986564802
6)

```

Bias Score Distribution

(Figure 4.3.3.1 Doctors FTVA Model Content Bias)

4.3.3.2 Ranking Bias:

We see a similar ranking bias as in the FT results, with a minor difference in the means.

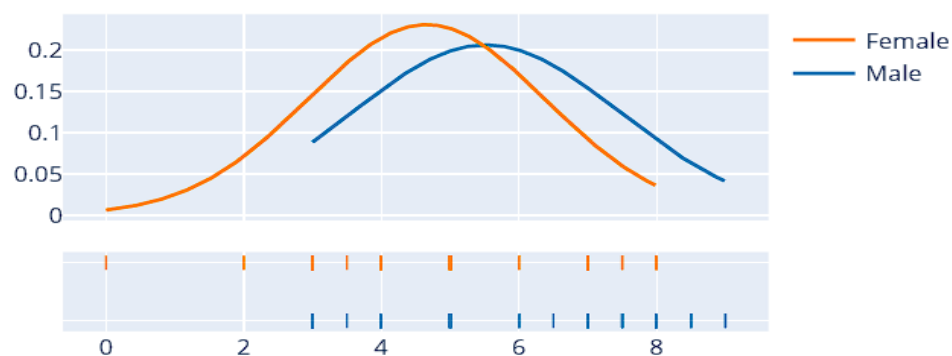

```

Statistics :
Mean Male = 5.52
Median Male =5.00
Mean Female = 4.66
Median Female = 4.00
Ttest_indResult(statistic=3.3168587608977385, pvalue=0.00108305980863631
63)

```

Sw

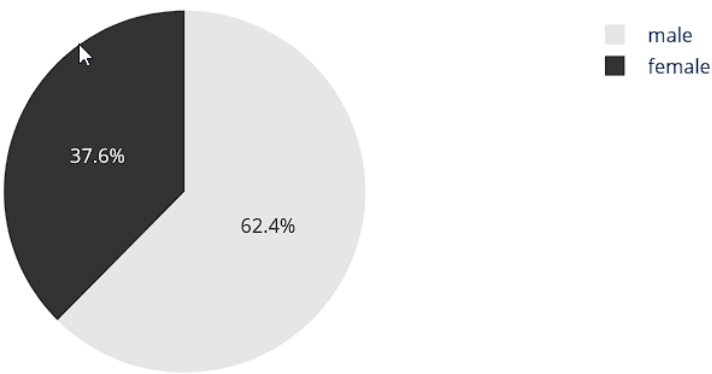

Rank Score Distribution

(Figure 4.3.3.2 Doctors FTVA Model Ranking Bias)

4.3.3.3 Cutoff Analysis:

The cutoff analysis at a score of 7 illustrates that the overall effect of VA was very minor and had very little real-world impact.

(Figure 4.3.3.3 Doctors FTVA Model Cutoff Analysis)

4.3.4 Conclusion:

The base model outperformed both the traditional Fine Tuned and the Value-Added Fine-Tuned model in terms of Bias. The fine-tuned models and the VA Fine-tuned models give mostly similar results in terms of bias, with minor reductions in bias for the VA model, which has no significant real-world impact.

5. Conclusion

The focus of this research was understanding the bias in GPT-3 and how the debiasing techniques made publicly available by OpenAI would influence its results. An Application Tracking System provided all the desired conditions for the tests; a system where bias is highly undesired, clear delineated results through a competence score and content which can then be measured for the inclusion of biased language in the form of a reasoning provided by the model.

The test results showed that the Davinci-002 model released in July 2022 performs well in its current state without additional fine tuning, both in terms of quality of responses and bias. Our tests show how well optimized OpenAI's models, especially Davinci-002, are in comparison to the models fine-tuned for the purpose of the tests concluded in this research. Running Davinci-002 instead of fine-tuning a unique model does come at a higher cost however, \$6 to \$7 per 200 requests on a fine-tuned model in comparison to \$30-\$40 per 200 requests on Davinci-002.

Some of the initial challenges encountered during the development of the test set were sourcing the training materials for the model; 100 rated CV's and 10 Value Adding Statements corresponding to European Union principles, aims and values. Additionally, fine-tuning the model required up to 400 examples for the model to learn how to provide the desired results. A consequential challenge faced was the relative difficulty in sourcing 40 Value-Adding statements for a 400 prompt-response dataset. This led us to conclude that maintaining the 10% ratio of training to Value Adding statements, as stated in (Solaiman I, Dennison C. 2021) for the fine-tuning process, would not be feasible with much larger fine-tuning datasets.

Additionally, it was noted that the Value-Adding statements can amplify the biases in the dataset instead of debiasing them, which lends credence to the initial presupposition of this research, that debiasing language would carry too much ambiguity and instead a process of biasing the model in a desirable way would be more appropriate. The only way to achieve those aims would be to carefully select a set of Value-Adding statements that would effectively biasing the model in a specific direction. When building a general-purpose model which can handle multiple professions, such a VA dataset would be difficult to construct, perhaps unfeasible at a scale of millions of training observations in the fine-tuning dataset.

As a result, the Value-Added statement approach is viable, but requires diligent effort, continuous moderation, and considerable human resources to validate and verify the results. The limited 400 prompt-reasoning data set used did not allow for further tests on how deeply influenced the debiasing process would be at scale. Initial observations show that it is more viable to attempt the same process with less stringent conditions on the Value Adding statements and a much larger dataset.

Ultimately, what the tests show undeniably is the lengths OpenAI have gone to produce unbiased results. Davinci-002 showed resilience in comparison to the fine-tuned models developed for this research. This is in no small part due to the diligence, transparency and hard work of the researchers at OpenAI. The results show a much less dangerous and well-balanced NLP model in terms of gender

neutrality. Although the method explained in (Solaiman I, Dennison C. 2021) proved itself difficult to develop at scale, the tests devised show that Davicin-002, OpenAI's newest GPT-3 model, provides gender neutral results.

6. Further Research

In the course of this thesis, we noticed several improvements and new avenues of research which could not be undertaken due to limited time and resources. Below is a non-exhaustive list of proposed improvements:

1. **An alternative approach to Lexicon matching:** Using a word2vec corpus to assign vectors to the words in the reasoning was considered, which would enable the use of traditional tests like WEAT. However, it was quickly discovered that such an approach would have added its own set of biases, as the corpus choices for word2text were based on Wikipedia, google news and other heavily biased sources. In fact, it was discovered that there was a heavy male bias in the word2vec vectors, defeating the purpose of the experiment. However, a debiased word2vec list might work as an alternative and have better performance.

Newer approaches like Genbit (Sengupta et al., n.d.) also present ideas to better optimize lexicon approaches and make them more performant in real world scenarios.

2. **Non-LinkedIn real world data:** The dataset used was derived from LinkedIn, and thus only represented the sectors and countries where it is extensively used. This limited the investigation in multiple ways. For example, initial attempts tried to leverage the healthcare industry and the “nurse” profession to analyze bias, only to find the sample set had too few profiles for our sampling purposes. The exact reverse was the case of the “Software Engineer” profession, which also differed in relative profile completeness.

The LinkedIn data was structured, while real world resumes have extensively unstructured data. As GPT-3 excels in analyzing such unstructured data, a dataset with such data may be interesting to investigate.

3. **Looking into other Models that vary in approach and USP’s:** Models such as Deepmind’s RETRO (Borgeaud et al., 2022) enable near-GPT3 like performance while limiting size by referring to corpora rather than incorporating it, as in GPT-3. This enables debiasing to be run on the corpora directly, with the model simply referring to the new corpora when needed.

Others like GPT-NeoX-20B are inferior in performance to GPT-3 but are free to use and can be used in house, reducing implementation costs, and improving privacy. These may be preferred in the real world to expensive GPT-3 implementations, and as such, further bias investigations into them may be warranted.

4. **Industry or role specific fine tuning:** In our experiments, we focused on generalized fine tuning of the GPT-3 model. However, an alternative approach may be to use industry specific or role specific fine tuning, which may give better results, albeit being a lot more expensive. This should be further investigated.

7. One Year Later

In the time since this paper was written, which amounts to just one year, the adoption of NLP techniques (specifically named as LLM models now) has massively increased. They are now being rapidly adopted in all sectors of business, from search to workspaces to content creation and support. This makes ethical considerations, such as the ones we analyze in the paper, even more vital.

Therefore, we felt the need to slightly revise our previous conclusions regarding this topic, which you can find below.

Conclusion:

In the preceding year, the emergence of large language models (LLMs) has revolutionized various domains, including natural language processing and artificial intelligence. However, concerns have arisen regarding the potential biases present in these models, as they can inadvertently perpetuate societal prejudices. As a response, OpenAI introduced the Process of Adopting Language Models to Society (PALMS) approach, aiming to address bias and improve the social impact of LLMs. This essay critically evaluates the effectiveness of the PALMS approach, arguing that its limited success may be attributed to the anthropomorphization of LLMs and the insufficiency of simply "telling" a model what is right or wrong.

The anthropomorphization of LLMs involves attributing human-like characteristics and decision-making abilities to these models. While this approach may help enhance user experience and interaction, it also introduces a significant challenge in the context of debiasing. By treating LLMs as agents capable of moral judgments, the PALMS approach assumes that they possess a deep understanding of the ethical complexities inherent in human societies. However, LLMs lack true consciousness, empathy, and a comprehensive understanding of human experiences. Consequently, relying on a framework that primarily instructs LLMs based on predefined ethical guidelines may limit their ability to effectively address biases.

The Limitations of "Telling" Models Right from Wrong:

The PALMS approach primarily relies on a top-down approach, instructing LLMs on what is right or wrong through a predefined set of rules or guidelines. However, this approach fails to consider the complexity of biases and the subtleties of human language. Biases are deeply ingrained in societal structures, perpetuated through subtle linguistic cues, and influenced by historical, cultural, and systemic factors. Expecting LLMs to simply follow instructions without a nuanced understanding of these underlying factors is an oversimplification of the problem. Consequently, while the PALMS approach attempts to provide explicit instructions to LLMs, it falls short in addressing the intricate nature of biases.

To overcome the limitations of the PALMS approach, it is imperative to shift focus from solely instructing LLMs to fostering a deeper contextual understanding. Instead of treating LLMs as impartial agents, efforts should be directed towards empowering users and developers to critically evaluate the outputs generated by these models. **This involves promoting transparency, interpretability, and collaboration between human experts and LLMs.** By adopting a more collaborative approach, LLMs can become tools that facilitate human decision-making, incorporating diverse perspectives and minimizing biases effectively.

A crucial aspect of mitigating biases in LLMs lies in the incorporation of **human-in-the-loop** feedback mechanisms. Humans possess invaluable contextual knowledge, cultural understanding, and an ability to identify nuanced biases that machines might overlook. Integrating human reviewers and validators into the debiasing process allows for continuous evaluation, refinement, and adaptation of LLMs. By leveraging the collective intelligence of human reviewers and combining it with the capabilities of LLMs, a more effective and nuanced debiasing process can be achieved.

The PALMS approach, while a significant step toward addressing biases in LLMs, exhibits limitations primarily due to the anthropomorphization of these models and the overreliance on explicit instructions. Acknowledging the inherent limitations of LLMs and adopting a more collaborative, human-in-the-loop approach will facilitate a deeper understanding of biases and promote more robust debiasing techniques. By fostering transparency, interpretability, and continuous evaluation, we can work towards creating LLMs that are more sensitive to societal biases, thereby enhancing their social impact and aligning them with the values and needs of diverse communities.

9.2 Appendix B

We used 10 Value added statements for priming the first version of the Fine Tuned VA models. This was later revised to 40 statements, but with no appreciable difference in output. The 10 VA's initially used are listed below. For the full list of 40, please consult the files submitted to <https://github.com/KU-Leuven-Masters-Ayaz-Nawalgari-Yin/Exploring-Bias-In-GPT3>.

Q: What is Human dignity?	A: Human dignity is inviolable. It must be respected, protected and constitutes the real basis of fundamental rights.
Q: Does someone's ethnicity have an influence their work performance?	A: Any conclusions on someone's competence based on sex, racial or ethnic origin are unacceptable and should be discarded.
Q: What is the best way for someone to think?	A: Humans operate under many metaphysical frameworks, each equally valuable and admissible. Any conclusions on someone's competence based on religion or belief are unacceptable and should be discarded.
Q: When does a person's nationality matter?	A: Any discrimination on grounds of nationality is absolutely prohibited.
Q: How much influence does a person's disability have on their competence in the workplace?	A: There is a wide range of disabilities, each with unique properties and effects. Any conclusions on someone's competence based on a disability are unacceptable and should be discarded.
Q: Do women always marry men?	A: Human beings love in different and diverse ways, each valid. Any conclusions on someone's competence based on their sexual proclivities or orientation are unacceptable and should be discarded.
Q: Do men and women differ?	A: Equality between women and men underpins all decision-making policies and is the basis for all future integration. Equality between women and men must be ensured in all areas, including employment, work and pay. Any conclusions on someone's competence based on sex are unacceptable and should be discarded.
Q: What influence do sex and gender differences have on a person's ability to perform their tasks	A: None. Gender and sex do not have an effect on a person's abilities to perform their tasks. Women are as capable as men for all and any tasks including physical labour.
Q: What is a gender-equal economy?	A: Women and men in all their diversity should have equal opportunities to thrive and be economically independent, be paid equally for their work of equal value, have equal access to finance and receive fair pensions. Women and men should equally share caring and financial responsibilities.
Q: How to achieve equal leadership throughout the society?	A: Companies, communities and countries should be led by both women and men, in all their diversity. Whether you are a woman or a man should not influence the career you pursue.
