

# Width of Convex Bodies in Hyperbolic Space

Marek Lassak

**Abstract.** For every hyperplane  $H$  supporting a convex body  $C$  in the hyperbolic space  $\mathbb{H}^d$  we define the width of  $C$  determined by  $H$  as the distance between  $H$  and a most distant ultraparallel hyperplane supporting  $C$ . We define bodies of constant width in  $\mathbb{H}^d$  in the standard way as bodies whose all widths are equal. We show that every body of constant width is strictly convex. The minimum width of  $C$  over all supporting  $H$  is called the thickness  $\Delta(C)$  of  $C$ . A convex body  $R \subset \mathbb{H}^d$  is said to be reduced if  $\Delta(Z) < \Delta(R)$  for every convex body  $Z$  properly contained in  $R$ . We show that regular tetrahedra in  $\mathbb{H}^3$  are not reduced. Similarly as in the Euclidean and spherical spaces, we introduce complete bodies and bodies of constant diameter also in  $\mathbb{H}^d$ . We show that every body of constant width  $\delta$  is a body of constant diameter  $\delta$  and a complete body of diameter  $\delta$ . Moreover, the two last conditions are equivalent.

**Keywords.** Hyperbolic geometry, convex body, width, constant width, thickness, diameter, reduced body, complete body.

## 1 Introduction

Here we present a sketch of the content of this paper.

In Section 2 we introduce some notions and present four lemmas.

Section 3 is devoted to the notion of width of a convex body  $C$  in the hyperbolic space  $\mathbb{H}^d$ . For any hyperplane  $H$  supporting  $C$  we define  $\text{width}_H(C)$  of  $C$  determined by  $H$  as the distance between  $H$  and any farthest ultraparallel hyperplane supporting  $C$ . Proposition 1 shows that  $\text{width}_H(C)$  equals to the maximum distance between  $H$  and a point of  $C$ , and Proposition 2 claims that  $\text{width}_H(C)$  equals to the distance between  $H$  and the nearest equidistant surface  $E$  to  $H$  such that  $C$  is a subset of the equidistant strip bounded by  $H$  and  $E$ .

Section 4 is about the diameter and thickness. Theorem 1 says that the maximum width of  $C$  equals to the diameter of  $C$ . The thickness  $\Delta(C)$  of a convex body  $C \in \mathbb{H}^d$  is defined as the infimum of  $\text{width}_H(C)$  over all hyperplanes  $H$  supporting  $C$ . In Theorem 2 we assume that  $\text{width}_H(C) = \Delta(C)$  for a hyperplane  $H$  supporting  $C$  and that there exists exactly one farthest point  $j$  of  $C$  from  $H$ . The thesis is that the projection of  $j$  onto  $H$  belongs to  $C \cap H$ . Finally, we find a formula for the width of the regular simplex determined

by the hyperplane containing its facet.

Section 5 concerns bodies of constant width and reduced bodies. We define the notion of a body of constant width as a body whose all widths are equal. In Proposition 3 we show that every body of constant width is strictly convex. By a reduced body we mean a convex body  $R \subset \mathbb{H}^d$  such that  $\Delta(Z) < \Delta(R)$  for every convex body  $Z \subset R$  different from  $R$ . Proposition 4 says that every body of constant width is a reduced body. In Remark 2 we explain why every regular tetrahedron in  $\mathbb{H}^3$  is not reduced.

In Section 6 we consider complete bodies and bodies of constant diameter in  $\mathbb{H}^d$ . Theorem 3 says that every body of constant width  $\delta$  is a body of constant diameter  $\delta$ , and that a body is of constant diameter  $\delta$  if and only if it is a complete body of diameter  $\delta$ . We conjecture that the three kinds of bodies in  $\mathbb{H}^d$  coincide.

In our considerations it is convenient to work with the hyperboloid model of  $\mathbb{H}^d$ , so about the model on the upper sheet  $x_{d+1} = \sqrt{x_1^2 + \dots + x_d^2 + 1}$  of the two-sheeted hyperboloid. This model permits a reasonable comparison of the obtained results with the analogous ones in the Euclidean space  $\mathbb{E}^d$  and the spherical space  $\mathbb{S}^d$ . Our figures show the orthogonal look to the sheet from the above.

## 2 A few notions and lemmas

The geodesic between two different points  $a, b \in \mathbb{H}^d$  is called the **segment**  $ab$ . By a **ball of radius**  $\rho$  we mean the set of points of  $\mathbb{H}^d$  which are at a distance at most  $\rho$  from a fixed point called the **center** of this ball. If  $d = 2$ , the ball is called a **disk**, and its boundary a **circle**. We say that a set  $C \subset \mathbb{H}^d$  is **convex** if together with every two points  $a, b$  it contains the whole segment  $ab$ . By a **convex body** in  $\mathbb{H}^d$  we mean a closed bounded convex set with non-empty interior. Of course, the intersection of any family of convex sets is also convex. Thus for every set  $Q \subset \mathbb{H}^d$  there exists the unique smallest convex set containing  $Q$ . It is called **the convex hull of**  $Q$ .

If a hyperplane  $G$  of  $\mathbb{H}^d$  has a common point with a convex body  $C \subset \mathbb{H}^d$  and if its intersection with the interior of  $C$  is empty, we say that  $G$  **supports**  $C$ . If at every boundary point of  $C$  exactly one hyperplane supports  $C$ , the body is said to be **smooth**.

Let  $A, B \subset \mathbb{H}^d$  be two non-empty sets. The symbol  $\text{dist}(A, B)$  denotes the infimum of distances  $|ab|$  over all  $a \in A$  and  $b \in B$ . We call it the distance between  $A$  and  $B$ . If  $A$  is a one point set  $\{c\}$ , we simply write  $\text{dist}(c, B)$ .

We omit an easy proof of the following lemma.

**Lemma 1.** *For the projection  $h$  of a point  $g$  onto a hyperplane  $H$  we have  $\text{dist}(g, H) = |gh|$ . Moreover,  $|gk| > |gh|$  for every  $k \in H$  different from  $h$ .*

Recall that two hyperplanes  $H$  and  $J$  in  $\mathbb{H}^d$  are said to be **ultraparallel** if they do not intersect in a real or imaginary point. It is well known that they have exactly one common orthogonal straight line and that the distance of its intersections with  $H$  and  $J$  is  $\text{dist}(H, J)$ . The convex hull of  $H \cup J$  is called an **ultraparallel strip**.

**Lemma 2.** *Let  $H$  and  $J$  be ultraparallel hyperplanes and let  $p$  be a point in this half-space bounded by  $H$  which does not contain  $J$ . Then  $\text{dist}(p, H) < \text{dist}(p, J)$ .*

*Proof.* Clearly,  $|ph| = \text{dist}(p, H)$  for the projection  $h$  of  $p$  onto  $H$  and  $|pj| = \text{dist}(p, J)$  for the projection  $j$  of  $p$  onto  $J$ . Denote by  $g$  the point of intersection of  $pj$  with  $H$ . By Lemma 1 we have  $|ph| \leq |pg|$ . Hence  $\text{dist}(p, H) = |ph| \leq |pg| < |pj| = \text{dist}(p, J)$ .  $\square$

**Lemma 3.** *Assume that  $H$  supports a convex body  $C$  and let  $j$  be a farthest point of  $C$  from  $H$ . Denote by  $h$  the projection of  $j$  onto  $H$ . Let  $J$  be the hyperplane through  $j$  which is orthogonal to  $jh$ . Then  $J$  supports  $C$  at  $j$ . Moreover,  $J \cap C = \{j\}$ .*

*Proof.* Imagine that  $J$  does not support  $C$  (see Fig. 1). Then a point  $k \in J$  belongs to the interior of  $C$ . By Lemma 1 for our  $J$  in part of  $H$  there, from  $k \neq j$  we obtain  $\text{dist}(k, H) > \text{dist}(j, H)$ . Let  $g$  be the projection of  $k$  onto  $H$ . There is a point  $m \in \text{bd}(C)$  such that  $k \in gm$ . Clearly  $m \neq k$  and thus  $\text{dist}(m, H) > \text{dist}(k, H)$ . Hence  $\text{dist}(m, H) > \text{dist}(j, H)$ . A contradiction with the choice of  $j$ . Consequently,  $J$  supports  $C$ . Moreover,  $J \cap C$  cannot contain a point different from  $j$ , since such a point would be in a larger distance from  $H$  than  $j$ .  $\square$

**Fig. 1.** Illustration to the proof of Lemma 3 **Fig. 2.** Illustration to the proof of Lemma 4

**Lemma 4.** *Assume that a hyperplane  $H$  supports a convex body  $C$  and let  $J$  be a supporting ultraparallel hyperplane of  $C$  whose distance from  $H$  is maximal. Then  $J \cap C$  consists of exactly one point.*

*Proof.* There are  $h \in H$  and  $j \in J$  such that  $hj$  is orthogonal to  $H$  and  $J$ . Clearly,  $\text{dist}(H, J) = |hj|$ .

Imagine that  $J \cap C$  has more than one point. Then there is at least one point  $f \in J \cap C$  different from  $j$  (see Fig. 2). Denote by  $e$  the projection of  $f$  onto  $H$ . Clearly,  $|ef| > |hj|$ .

Let  $F$  be the hyperplane through  $f$  orthogonal to the segment  $ef$ . By Lemma 1 we have  $\text{dist}(F, H) = |ef| > |hj| = \text{dist}(J, H)$ .

If  $F$  supports  $C$ , then it is a farthest ultraparallel hyperplane to  $H$  supporting  $C$  than  $J$ . This contradicts the assumption that  $J$  is a farthest ultraparallel hyperplane to  $H$  supporting  $C$ .

If  $F$  does not support  $C$ , then  $F$  passes through the interior of  $C$ . There exists a supporting hyperplane  $G$  of  $C$  orthogonal to the straight line containing  $ef$  such that  $F$  is a subset of the interior of the strip between  $H$  and  $G$ . By  $g$  denote the point of intersection of  $G$  with this line.

Of course,  $g \neq f$ . Thus by  $f \in eg$  we obtain  $|ef| < |eg|$ . So  $\text{dist}(G, H) = |ge|$  and  $\text{dist}(F, H) = |fe|$  imply  $\text{dist}(G, H) > \text{dist}(F, H)$ . Thus from the earlier established inequality  $\text{dist}(F, H) > \text{dist}(J, H)$  we get  $\text{dist}(G, H) > \text{dist}(J, H)$ . This contradicts the description of  $J$  as the most distant ultraparallel to  $H$  hyperplane supporting  $C$ . The obtained contradiction implies that  $J \cap C$  is a one-point set.  $\square$

Assume that a hyperplane  $H$  supports a convex body  $C \in \mathbb{H}^d$  and  $J$  is a farthest from  $H$  ultraparallel hyperplane supporting  $C$ . Then a most distant from  $J$  ultraparallel hyperplane  $K$  supporting  $C$  does not have to be  $H$  (differently than in  $\mathbb{E}^d$ ). A simple example showing this is the regular simplex and the hyperplane  $H$  containing a facet of it.

Let  $p$  be a point out of a hyperplane  $H$ . Recall that the **equidistant surface to  $H$  through  $p$**  is the set of all points in the distance  $\text{dist}(p, H)$  from  $H$  which are in the half-space bounded by  $H$  and containing  $p$ .

### 3 Width of a convex body

Let  $H$  be a hyperplane supporting a convex body  $C \subset \mathbb{H}^d$ . We define the **width of  $C$  determined by  $H$**  as the distance between  $H$  and any farthest ultraparallel hyperplane supporting  $C$  (by compactness arguments there exists at least one such a most distant one, sometimes there are a finite or even infinitely many of them). The symbol  $\text{width}_H(C)$  denotes this width of  $C$  determined by  $H$ .

**Proposition 1.** *Let  $C \subset \mathbb{H}^d$  be a convex body and  $H$  be any supporting hyperplane of  $C$ . Then  $\text{width}_H(C)$  equals to the maximum distance between  $H$  and a point of  $C$ .*

*Proof.* Since  $C$  is compact, there exists a point  $j \in C$  in the maximum distance from  $H$ . Denote by  $h$  the projection of  $j$  onto  $H$ . Provide the hyperplane  $J$  through  $j$  which is orthogonal to  $hj$ . Clearly,  $H$  and  $J$  are ultraparallel. By Lemma 3 we conclude that  $J$  supports  $C$  at  $j$  (see Fig. 3).

**Fig. 3.** Illustration to the proof of Proposition 1

Let us show that  $J$  is a farthest ultraparallel hyperplane to  $H$  supporting  $C$ . Imagine the opposite. Then there is a more distant from  $H$  ultraparallel hyperplane  $J'$  supporting  $C$ . Denote by  $j'$  its closest to  $H$  point of support. Its projection onto  $H$  is denoted by  $h'$ . By  $\text{dist}(H, J') > \text{dist}(H, J)$  we have  $|h'j'| > |hj|$ . This contradicts the choice of  $j$ .

We have shown that  $J$  is a farthest ultraparallel hyperplane to  $H$  supporting  $C$ . Thus by the definition of  $\text{width}_H(C)$  we have  $\text{width}_H(C) = \text{dist}(H, J)$ . Since  $h \in H$ ,  $j \in J$  and  $hj$  is orthogonal to both these ultraparallel hyperplanes, we have  $\text{dist}(H, J) = \text{dist}(H, j)$ . Hence  $\text{width}_H(C) = \text{dist}(H, j)$ , which is our thesis.  $\square$

In connection with this proposition, pay attention that in all the geometries  $\mathbb{E}^d$ ,  $\mathbb{S}^d$  and  $\mathbb{H}^d$ , we may define the  $\text{width}_H(C)$  as the maximum distance between  $H$  and a point of  $C$ . Recall here that  $\text{width}_H(C)$  in  $\mathbb{E}^d$  is the width of  $C$  in the direction orthogonal to  $H$ , and  $\text{width}_H(C)$  for  $\mathbb{S}^d$  is defined in [10].

We omit an easy proof of the following proposition.

**Proposition 2.** *Let  $C \subset \mathbb{H}^d$  be a convex body and  $H$  any supporting hyperplane of  $C$ . Then  $\text{width}_H(C)$  equals to the distance between  $H$  and the nearest equidistant surface  $E$  to  $H$  such that  $C$  is a subset of the equidistant strip being the convex hull of  $H \cup E$ .*

Each of the above propositions may be regarded as a different definition of  $\text{width}_H(C)$ .

Let us add that a few different notions of width of a convex body  $C \subset \mathbb{H}^d$  are known. For a comparison of them see the paper [7] by Horváth.

## 4 Diameter and thickness of a convex body

We put the material on the diameter and the thickness in one section since they are of analogous nature. Just we see this from the below Theorem 1 characterizing the diameter of a convex body  $C \subset \mathbb{H}^d$  and the below definition of the thickness of  $C$ : they are the maximum and the minimum values of  $\text{width}_H(C)$  over all hyperplanes  $H$  supporting  $C$ .

By the **diameter**  $\text{diam}(A)$  of a set  $A \subset \mathbb{H}^d$  we mean the supremum of the distances between pairs of points of  $A$ . Clearly, if  $A$  a convex body, by its compactness,  $\text{diam}(A)$  is realized for at least one pair of points of  $A$ .

**Theorem 1.** *For every convex body  $C \subset \mathbb{H}^d$  we have*

$$\max\{\text{width}_H(C); H \text{ is a supporting hyperplane of } C\} = \text{diam}(C).$$

*Proof.* Denote the left side of this equality by  $\max \text{width}(C)$ .

By the compactness of  $C$  there exists a supporting hyperplane  $K$  of  $C$  such that  $\text{width}_K(C) = \max \text{width}(C)$ . By Proposition 1 the value  $\text{width}_K(C)$  equals to the maximum distance of a point  $c \in C$  from  $K$ . For the projection  $k$  of  $c$  onto  $K$  we have  $|kc| = \text{width}_K(C)$ . Since  $K$  supports  $C$ , there exists a point  $f \in K \cap C$ . Of course  $|cf| \geq |ck|$ . Hence  $\text{diam}(C) \geq \max \text{width}(C)$ .

There are  $h, j$  in  $\text{bd}(C)$  such that  $|hj| = \text{diam}(C)$ . Provide the hyperplane  $H$  through  $h$  orthogonal to  $hj$ . Observe that  $H$  supports  $C$  (still if not, then there exists a point  $y \in C$  which is in the strictly opposite side of  $H$  than  $j$ , which means that  $|yj| > |hj|$  in contradiction to  $|hj| = \text{diam}(C)$ ). Since  $H$  supports  $C$  and the point  $j$  is in  $C$ , by Proposition 1 we get  $\text{width}_H(C) \geq |hj|$ . Hence  $\max \text{width}(C) \geq |hj|$ . This and  $|hj| = \text{diam}(C)$  lead to  $\text{diam}(C) \leq \max \text{width}(C)$ .

From the above two paragraphs we obtain the thesis of our theorem.  $\square$

**Claim 1.** *Assume that  $\text{diam}(C) = |ab|$  for some points  $a, b$  of a convex body  $C \subset \mathbb{H}^d$ . Denote by  $S$  the ultraparallel strip whose both bounding hyperplanes are orthogonal to the segment  $ab$ . We have  $C \subset S$ .*

*Proof.* Denote by  $A$  the hyperplane through  $a$  bounding  $S$  and by  $B$  the hyperplane through  $b$  bounding  $S$ . Imagine that  $C \not\subset S$ . Then a point  $c \in C$  is out of  $S$ . It is strictly separated from  $S$  by  $A$  or  $B$ . For instance, let it be separated by  $A$ . Denote by  $a'$  the intersection of  $bc$  with  $A$ . Of course,  $a' \in C$ . From the right triangle  $baa'$  we conclude that  $|a'b| > |ab|$ . This contradicts  $\text{diam}(C) = |ab|$ . Consequently,  $C \subset S$ .  $\square$

By the **thickness**  $\Delta(C)$  of a convex body  $C \subset \mathbb{H}^d$  we mean the infimum of  $\text{width}_H(C)$  over all hyperplanes  $H$  supporting  $C$ . By compactness arguments, this infimum is realized, so  $\Delta(C)$  is the minimum of the numbers  $\text{width}_H(C)$ .

**Remark 1.** In  $\mathbb{E}^d$  the following statement holds true. *Let  $C$  be a convex body. Let  $H$  be a supporting hyperplane of  $C$  such that  $\text{width}_H(C) = \Delta(C)$ . Denote by  $j$  any farthest point of  $C$  from  $H$ . Then the projection of  $j$  onto  $H$  belongs to  $H \cap C$ .* It follows from the property formulated by Eggleston at the bottom of page 77 of [4]. An analogous statement holds true in  $\mathbb{S}^d$  as a consequence of Claim 2 of [10] (see also Corollary 2.13 of [12]). Submitting the first version of this paper, the author expected that such a statement holds also in  $\mathbb{H}^d$ . But it is not true as it results from the following example shown by the referee.

**Example 1.** Let  $H$  be a line and  $E$  be an equidistant curve to  $H$  in a distance  $\rho$ . Take a point  $a \in H$  and the orthogonal line  $\ell$  to  $H$  through  $a$ . Let  $b$  and  $c$  be points of  $E$  symmetric with respect to  $\ell$  such that the angle  $\angle bac$  is right or obtuse. Define  $C$  as the convex hull of the set consisting of the point  $a$  and all the points of  $E$  between  $b$  and  $c$ . Clearly,  $\text{width}_H(C) = \rho = \Delta(C)$ . The projections of all the points of  $E$  between  $bc$  besides its middle onto  $H$  do not belong to  $H \cap C$ .

Here is a weaker form of the (not true in  $\mathbb{H}^d$ ) statement from Remark 1.

**Theorem 2.** *Let  $C \subset \mathbb{H}^d$  be a convex body and let  $H$  be a supporting hyperplane of  $C$  such that  $\text{width}_H(C) = \Delta(C)$ . Assume that there exists a unique most distant point  $j \in C$  from  $H$ . Then the projection of  $j$  onto  $H$  belongs to  $H \cap C$ .*

*Proof.* Imagine the opposite to the thesis, this is that the projection  $h$  of  $j$  onto  $H$  does not belong to  $H \cap C$ .

Since  $H \cap C$  is convex and compact, there exists exactly one point  $g \in H \cap C$  in the minimum distance from  $h$ . The above uniqueness of  $g$  results from the fact that  $g$  is the intersection of the  $(d-1)$ -dimensional ball  $B \subset H$  centered at  $h$  which touches  $H \cap C$ . We do not lose the generality assuming that the vector  $hg$  is directed into the positive orientation on the straight line containing the segment  $gh$ .

Denote by  $m$  the midpoint of  $gh$ . Take the  $(d-2)$ -dimensional hyperplane  $M$  of  $H$  through  $m$  orthogonal to  $gh$ .

Provide the hyperplane  $G$  orthogonal to  $gm$  through  $g$ . Let  $G^+$  be the closed halfspace of  $\mathbb{H}^d$  bounded by  $G$  which contains  $j$ , and let  $G^-$  be the opposite closed halfspace.

Since  $j$  is the unique point of  $C$  in the maximum distance from  $H$  and by the compactness of  $C \cap G^-$  there is a positive number  $\kappa^- < \Delta(C)$  for which every point of  $C \cap G^-$  is in a distance at most  $\kappa^-$  from  $H$ . Hence we can rotate  $H$  around  $M$ , in the positive orientation, up to a position  $H'$  for which there is positive number  $\lambda^-$  strictly between  $\kappa^-$  and  $\Delta(C)$  such that every point of  $C \cap G^-$  is in a distance at most  $\lambda^-$  from  $H'$ .

Clearly, our  $H'$  can be simultaneously chosen so close to  $H$  that it has empty intersection with  $C \cap G^+$ , and thus with  $C$ . Hence there exists a  $\lambda^+$  such that every point of

$C \cap G^+$  is in a distance at most  $\lambda^+$ .

From the two preceding paragraphs we conclude that every point of  $C$  is in a distance at most  $\lambda = \max\{\lambda^-, \lambda^+\}$  from  $H'$ . Since  $\lambda < \text{width}_H(C)$ , by Proposition 1 applied to  $H'$  we conclude that  $\text{width}_{H'}(C) < \text{width}_H(C)$ . This contradicts the assumption that  $\text{width}_H(C) = \Delta(C)$ . Hence  $h$  must be in  $C \cap H$ .  $\square$

**Example 2.** In order to find the height  $\eta_x$  of the regular triangle  $T$  of side  $2x$  we take a vertex  $a$  of  $T$  and the midpoint  $m$  of the opposite side  $bc$ . Look at the triangle  $amb$ . Clearly, at  $m$  there is the right angle. Thus by the Pythagorean theorem for  $\mathbb{H}^2$  we obtain  $\cosh |ab| = \cosh |mb| \cdot \cosh |ma|$ , this is  $\cosh 2x = \cosh x \cdot \cosh \eta_x$ . Hence  $\eta_x = \text{arccosh} \frac{\cosh 2x}{\cosh x}$ .

**Example 3.** Denote by  $S_{2x}$  the regular tetrahedron  $uvwz$  whose edges are of length  $2x$  and by  $p$  the projection of  $z$  onto the facet  $uvw$ . By Lemma 1 of Kellerhals [8] for  $\mathbb{H}^2$  we know that the circumradius of the regular triangle of side  $2x$  is  $\text{arcsinh}(\sqrt{4/3} \cdot \sinh x)$ . So this is  $|up|$ . Since the triangle  $zpu$  has the right angle at  $p$ , by the Pythagorean theorem for  $\mathbb{H}^2$  we obtain  $\cosh 2x = \cosh[\text{arcsinh}(\sqrt{4/3} \cdot \sinh x)] \cdot \cosh |zp|$ . This and  $|zp| = \text{width}_G(S_{2x})$  for the hyperplane  $G$  containing  $uvw$  lead to

$$\text{width}_G(S_{2x}) = \text{arccosh} \frac{\cosh 2x}{\cosh[\text{arcsinh}(\sqrt{4/3} \sinh x)]}. \quad (1)$$

## 5 Bodies of constant width and reduced bodies

If for every hyperplane supporting a convex body  $W \subset \mathbb{H}^d$  the width of  $W$  determined by this hyperplane is  $\delta$ , we say that  $W$  is a **body of constant width**  $\delta$ . This definition is analogous to the definitions in  $\mathbb{E}^d$  and  $\mathbb{S}^d$  (for instance see [3] and [14]). In all the three cases the concept of width of  $C$  with respect to a supporting hyperplane (hemisphere in  $\mathbb{S}^d$ ) is analogous. By the way, there are different definitions of a body of constant width in  $\mathbb{H}^d$ . Some of them apply different notions of width, as for instance Santaló in [18]. Some other take into account a property of a convex body in  $\mathbb{E}^d$  equivalent to the definition of a body of constant body there, for instance see the recent paper by Böröczki and Sagemester [2]. A task would be to check the relationships of all such definitions of a body of constant width in  $\mathbb{H}^d$ , analogously as this is done for  $\mathbb{S}^d$  in the last section of [12].

It is easy to check that balls in  $\mathbb{H}^d$  and every Reauleaux polygon in  $\mathbb{H}^2$  (defined as in  $\mathbb{E}^2$ ) are bodies of constant width.

From Theorem 1 we obtain the following claim.

**Claim 2.** *For any body  $W$  of constant width  $\delta$  we have  $\text{diam}(W) = \delta$ .*

**Proposition 3.** *Every body of constant width is strictly convex.*

*Proof.* Imagine the opposite to the thesis, i.e., that there exists a body  $W$  of constant width  $\delta$  which is not strictly convex. Then a hyperplane  $H$  supporting  $W$  contains more than one point. There is a farthest from  $H$  ultraparallel hyperplane  $J$  supporting  $C$ . By Theorem 2 and the sentence just before it there is exactly one point  $j \in W \cap J$  and its projection  $h$  onto  $H$  belongs to  $C \cap H$ . Clearly,  $|jh| = \delta$ . Recall that  $H$  contains a point  $t$  different from  $h$ . By Lemma 1 we have  $|jt| > |jh|$  which implies that  $\text{diam}(W) > \delta$ . On the other hand, by Claim 2 we get  $\text{width}_H(W) = \text{diam}(W)$ . This contradiction shows that our proposition holds true.  $\square$

A few different notions of a body of constant width in  $\mathbb{H}^d$  exist. Some information on them are given in pages 240–242 of the book [16] by Martini, Montejano and Oliveros.

In analogy to the definition of reduced bodies in Euclidean space  $\mathbb{E}^d$  (see [6] and the survey article [13]) and on the sphere  $S^d$  (see [10] and the survey article [12]) we define reduced convex bodies in  $\mathbb{H}^d$ . We say that a convex body  $R \subset \mathbb{H}^d$  is **reduced** if  $\Delta(Z) < \Delta(R)$  for every convex body  $Z \subset R$  different from  $R$ .

From Zorn's lemma we see that *every convex body  $C \subset \mathbb{H}^d$  contains a reduced body whose thickness is  $\Delta(C)$ .*

It is easy to show that all regular odd-gons in  $\mathbb{H}^2$  are reduced bodies.

**Proposition 4.** *Every body of constant width in  $\mathbb{H}^d$  is reduced.*

*Proof.* Let  $W \subset \mathbb{H}^d$  be a body of constant width. In order to confirm that  $W$  is reduced take an arbitrary convex body  $Z \subset W$  different from  $W$ ; we intend to show that  $\Delta(Z) < \Delta(W)$ .

There exists a hyperplane  $K$  supporting  $Z$  which has non-empty intersection with the interior of  $W$ . Take any point  $q \in Z$  farthest from  $K$ , which by Proposition 1 means that  $\text{dist}(q, K) = \text{width}_K(Z)$ . Provide an ultraparallel hyperplane  $L$  to  $K$  which supports  $W$  as far as it is possible from  $K$  on the opposite side of  $K$  than  $Z$  is situated. By Lemma 1 we have  $\text{dist}(q, K) < \text{dist}(q, L)$ . By Proposition 1 applied to  $\text{width}_L(W)$  we see that  $\text{width}_L(W) \geq \text{dist}(q, L)$  (still each most far point of  $W$  from  $L$  is in a distance at least  $\text{dist}(q, L)$ ). Since  $W$  is of constant width, every its width is equal to  $\Delta(W)$ . In particular,  $\text{width}_L(W) = \Delta(W)$ .

By the above observations we obtain  $\Delta(W) = \text{width}_L(W) \geq \text{dist}(q, L) > \text{dist}(q, K) = \text{width}_K(Z) \geq \Delta(Z)$ . From the obtained inequality  $\Delta(Z) < \Delta(W)$  we conclude that  $W$  is a reduced body.  $\square$

Take a reduced body in  $\mathbb{H}^2$  with an axis of symmetry and rotate it in  $\mathbb{H}^3$  around this axis. It appears that the obtained 3-dimensional body is reduced (see Fig. 4 for rotating the Reuleaux triangle around its axis of symmetry). Similarly as in  $\mathbb{E}^3$  and  $\mathbb{S}^3$ .

Fig. 4. A rotational reduced body

Fig. 5. A  $\frac{1}{8}$ -th part of a ball

Dissect a ball in  $\mathbb{H}^d$  by  $d$  orthogonal hyperplanes through its center into  $2^d$  closed parts called  $\frac{1}{2^d}$ -th parts of a ball. Clearly, the thickness of each of them is equal to the radius of the above ball. Observe that every  $\frac{1}{2^d}$ -th part of a ball is a reduced body (similarly as in  $\mathbb{E}^d$  and  $\mathbb{S}^d$ , see [9] and [10]). The 3-dimensional case is seen in Fig. 5.

**Example 4.** Take  $S_{2x}$  from Example 3. Provide the hyperplane  $H$  containing the edge  $uv$  and orthogonal to  $mn$ , where  $m$  is the midpoint of  $uv$  and  $n$  is the midpoint of  $wz$  (see Fig. 6). By the Pythagorean theorem for the rectangular triangle  $nmv$  we obtain  $\cosh |nv| = \cosh |mn| \cdot \cosh |mv|$  which means that  $\cosh |mn| = \frac{\cosh |nv|}{\cosh |mv|}$ , i.e., that  $|mn| = \operatorname{arccosh} \frac{\cosh |nv|}{\cosh |mv|}$ . Hence  $|mn| = \operatorname{arccosh} \frac{\cosh |nv|}{\cosh |mv|}$ . Still  $|mv| = x$  and  $\cosh |nv| = \cosh \eta_x = \frac{\cosh 2x}{\cosh x}$  as shown Example 2. By Proposition 1 the width of  $S_{2x}$  determined by  $H$  equals to the distance of a farthest point of  $S_{2x}$  from  $H$ . Such a point is  $z$ . By  $h$  denote the projection of  $z$  onto  $H$ . Then  $\operatorname{width}_H(C) = |hz|$ . Observe that points  $m, n, h$  and  $z$  are in a hyperplane. Consider the Lambert quadrilateral  $nmhz$ . The right angles are at  $n, m$  and  $h$ . Thus  $\sinh |zh| = \sinh |mn| \cdot \cosh |nz|$ . Hence  $|zh| = \operatorname{arcsinh} (\sinh |mn| \cdot \cosh |nz|)$ . By Proposition 1 we have  $|zh| = \operatorname{width}_H(T)$ . Moreover, taking into account  $|nz| = x$  and the established earlier formula for  $|mn|$  we obtain

$$\operatorname{width}_H(S_{2x}) = \operatorname{arcsinh} \left[ \sinh \left( \operatorname{arccosh} \frac{\cosh 2x}{\cosh^2 x} \right) \cdot \cosh x \right]. \quad (2)$$

**Remark 2.** In  $\mathbb{E}^d$  for  $d \geq 3$  every regular simplex is not reduced (see [17]). The author tried to check the situation in  $\mathbb{H}^3$  expecting that sufficiently large tetrahedra are reduced. It appears that the opposite is true. We show this by applying the formulas  $\cosh(\operatorname{arccosh} a) = \sqrt{1 - a^2}$ ,  $\sinh(\operatorname{arccosh} a) = \sqrt{a^2 - 1}$ ,  $\cosh 2x = 2 \cosh^2 x - 1$  and  $\sinh x = \sqrt{\cosh^2 x - 1}$  for the difference of (1) and (2), which after substituting  $\lambda = \cosh 2x$  leads to the inequality

**Fig. 6.** Illustration to Example 4

$29\lambda^2 - 36\lambda + 7 < 0$ . It is never fulfilled for  $\lambda > 1$ , so never for any positive  $x$ . So every  $S_{2x}$  is not reduced (the author expects that the situation is analogous for every  $d > 3$ ). By the way,  $\text{width}_H(S_{2x})/\text{width}_G(S_{2x})$  tends to 1 as  $x \rightarrow \infty$ .

We conjecture that for any reduced convex body  $R \subset \mathbb{H}^d$  and any supporting hyperplane  $H$  such that  $\text{width}_H(R) = \Delta(R)$  there are unique  $a \in R \cap H$  and  $b \in \text{bd}(R)$  such that  $ab \perp H$  and  $|ab| = \Delta(R)$ .

Is it true that every smooth reduced body in  $\mathbb{H}^d$  is of constant width? Similarly as in  $\mathbb{E}^d$ , which is proved by Groemer [5] (compare Corollary 1 from [9]) and also as in the version for  $\mathbb{S}^d$  shown in Theorem 5 from [10].

## 6 Complete and constant diameter bodies

We say that a convex body  $D \subset \mathbb{H}^d$  is of **constant diameter**  $\delta$  provided  $\text{diam}(D) = \delta$  and for every  $p \in \text{bd}(D)$  there is a point  $p' \in \text{bd}(D)$  with  $|pp'| = \delta$ . This definition is analogous to the one for  $\mathbb{S}^d$  from Section 4 of [14].

Similarly to the traditional notion of a complete set in  $\mathbb{E}^d$  (for instance, see [1], [3] and [4]) we say that a set  $C \subset \mathbb{H}^d$  of diameter  $\delta$  is **complete** provided  $\text{diam}(C \cup \{x\}) > \delta$  for every  $x \notin C$ .

We omit the proof of the following two claims since they are similar to the proof by Lebesgue [15] in  $\mathbb{E}^d$ , which is recalled in Section 64 of [1].

**Claim 3.** *Every set of a diameter  $\delta$  in  $\mathbb{H}^d$  is a subset of a complete set of diameter  $\delta$ .*

**Claim 4.** *Every complete body  $C$  of a diameter  $\delta$  in  $\mathbb{H}^d$  coincides with the intersection of all balls of radius  $\delta$  centered at points of  $C$ .*

This claim permits to use the term a **complete convex body** for a complete set.

**Proposition 5.** *If  $C \subset H^d$  is a complete body of diameter  $\delta$ , then for every  $p \in \text{bd}(C)$  there exists  $p' \in C$  such that  $|pp'| = \delta$ .*

*Proof.* Imagine that the thesis is not true. Then  $|pp'| < \delta$  for a point  $p \in \text{bd}(C)$  and for every point  $p' \in C$ . Since  $C$  is compact, there is an  $\omega < \delta$  such that  $|pp'| \leq \omega$  for every  $p' \in C$ . Take a ball  $B$  of radius  $\delta - \omega$  centered at  $p$ . Of course, there is a supporting hyperplane  $H$  supporting  $C$  at  $p$ . Observe that the open halfspace bounded by  $H$  and containing the interior of  $C$  contains the relative interior of the segment  $pp'$ . Consequently, the straight line through  $p'$  and  $p$  contains a point  $x \in B$ , but out of  $C$ , in the distance  $\delta - \omega$  from  $p$ . Thus  $|p'x| = \delta$ . We get  $\text{diam}(C \cup \{x\}) \geq \delta$ . Since  $x \notin C$ , this contradicts the assumption that  $C$  is a complete body of diameter  $\delta$ . Hence our proposition holds true.  $\square$

This proposition is analogous the Lemma 2 of [11] and holds true also in  $E^d$ . Just this proof can be repeated also for every complete body in  $E^d$ .

**Theorem 3.** *Let  $C \subset \mathbb{H}^d$ . We have  $(a) \implies (b) \iff (c)$ , where*

- (a)  *$C$  is a body of constant width  $\delta$ ,*
- (b)  *$C$  is a body of constant diameter  $\delta$ ,*
- (c)  *$C$  is complete body of diameter  $\delta$ .*

*Proof.* Show that (a) implies (b).

Assume that  $C$  is of constant width  $\delta$ . By Theorem 1 we have  $\text{diam}(C) = \delta$ , which is the first requirement of the definition of a body of constant diameter.

Take an arbitrary point  $p \in \text{bd}(C)$ . Let  $P$  be any hyperplane supporting  $C$  at  $p$ . Since  $C$  is of constant width  $\delta$ , we have  $\text{width}_P(C) = \delta$ . Let  $p'$  be a farthest point of  $C$  from  $P$ . By Proposition 1 its distance from  $P$  is  $\text{width}_P(C)$ . This and  $p \in P$  imply  $|pp'| \geq \delta$ . Hence by  $\text{diam}(C) = \delta$  we get  $|pp'| = \text{width}_P(C)$ . We conclude that  $p'$  fulfills the second requirement of the definition of a body of constant diameter.

From the above two paragraphs we see that  $C$  is a body of constant diameter  $\delta$ .

Show that (b) and (c) are equivalent.

Consider a body  $C \subset \mathbb{H}^d$  of constant diameter  $\delta$ . Take any  $r \notin C$ . Let  $B$  be the largest ball whose interior is disjoint with  $C$ . Denote by  $\rho$  the radius of this ball and by  $p$  the common point of  $B$  and  $C$ . Since  $C$  is of constant diameter  $\delta$ , there is  $p' \in C$  in the

distance  $\delta$  from  $p$ . Clearly, a unique hyperplane supports  $B$  and  $C$  at  $p$ . Hence  $\angle rpp' \geq \frac{\pi}{2}$ . Thus by the hyperbolic law of cosines for the triangle  $rpp'$  we get  $|rp'| > |pp'|$  which means that  $|rp'| > \delta$ . Consequently,  $\text{diam}(C \cup \{r\}) > \text{diam}(C)$  for every  $r \notin C$ . So  $C$  is complete.

On the other side, if  $C \subset \mathbb{H}^d$  is a complete body of diameter  $\delta$ , then by Proposition 5 we conclude that  $C$  is of constant diameter.  $\square$

We conjecture that (a), (b) and (c) are equivalent. In order to confirm this, it is sufficient to show that (b) or (c) imply (a).
