The fascinating concept of coherent quantum absorber—which can absorb any photon emitted by another system while maintaining entanglement with that system—has found diverse implications in open quantum system theory and quantum metrology. This work generalizes the concept by proposing the so-called reversal conditions for the two systems, in which a “reverser” coherently reverses any effect of the other system on a field. The reversal conditions are rigorously boiled down to concise formulas involving the Petz recovery map and Kraus operators, thereby generalizing as well as streamlining the existing treatments of coherent absorbers.

1. INTRODUCTION

A coherent quantum absorber, as conceived by Stannigel *et al.* [1], is a system that absorbs any light emitted by another system while maintaining entanglement with that system. The idea has since found surprising implications, such as a technique for finding the steady states of open quantum systems [1–3] and a method for constructing efficient continuous measurements for quantum parameter estimation [4, 5]. Remarkably, Yang, Huelga, and Plenio [5] have recently shown that a method of measurement-backaction-noise cancellation [6–9]—which has seen significant experimental progress with atomic and optomechanical systems in recent years [10–12]—can be regarded as a special case of coherent absorbers. This relation extends the potential impact of the absorber concept to the areas of magnetometry, optomechanics, and gravitational-wave detectors.

While the absorber concept is fascinating and promising, many special assumptions and a bewildering array of theoretical tools have been invoked to study it, such as quantum Markov semigroups, cascaded quantum networks [1], matrix-product states [5], and quantum detailed balance [3, 13]. The goal of this work is to tease out the essential ideas and make the absorber notion more rigorous as well as generalizable to other scenarios, far beyond the narrow setting of photon emission and absorption considered in prior works.

This generality calls for a different name for the generalized absorber conditions proposed here—I call them the reversal conditions. The key appeal of the reversal conditions is that they can be boiled down to concise formulas in terms of judiciously chosen concepts in open quantum system theory. Out go the quantum Markov semigroups, the matrix-product states, and many other extraneous concepts; in come antiunitary operators [3, 14], the Petz recovery map [15], and Kraus operators [16] as the more fundamental ingredients of the reversal conditions.

This work is organized as follows. Sec. 2 introduces the basic model and defines the reversal condition. Sec. 3 discusses how a quantum detailed balance condition proposed by Fagnola and Umanità [13] can simplify the reversal condition. Sec. 4 introduces a special reversal condition that eliminates an ambiguity in the general condition and may be more useful in experiment design. Theorem 2.1 and 4.1 are the key results that translate the conditions to the promised formulas, while Example 4.1 offers a more physical scenario to illustrate the theory.

2. REVERSAL CONDITION

A. Model

Consider the model depicted by Fig. 1. Two systems, denoted as systems A and B, are initially in a pure state $|\psi\rangle_{AB}$ in Hilbert space $\mathcal{H}_A \otimes \mathcal{H}_B$. A temporal mode of a traveling field with initial state $|\chi\rangle_E$ in Hilbert space $\mathcal{H}_E$ interacts with system A according to a unitary operator U on $\mathcal{H}_A \otimes \mathcal{H}_E$. The field mode then evolves according to an intermediate unitary operator U_E on $\mathcal{H}_E$, before interacting with system B according to a unitary operator V on $\mathcal{H}_B \otimes \mathcal{H}_E$. A generalization of this model for interactions with multiple field modes will be discussed in Sec. 3. All Hilbert spaces are assumed to be finite-dimensional in the proofs for simplicity.

FIG. 1. A quantum circuit illustrating the interactions between system A, system B, and the field mode.

Let $\mathcal{O}(\mathcal{H})$ be the set of operators on Hilbert space $\mathcal{H}$. An operator on operators is called a map in this work, also called a superoperator in the literature. With $|\chi\rangle_E$ and U , a channel for system A can be modeled by a completely positive, trace-preserving (CPTP) map $\mathcal{F} : \mathcal{O}(\mathcal{H}_A) \rightarrow \mathcal{O}(\mathcal{H}_A)$ given by

$$\boxed{\mathcal{F}\rho_A \equiv \text{tr}_E U(\rho_A \otimes |\chi\rangle_E \langle\chi|) U^\dagger,} \quad (2.1)$$

where ρ_A is an arbitrary density operator on $\mathcal{H}_A$, $\text{tr}_{xy\dots}$ is the partial trace with respect to $\mathcal{H}_x \otimes \mathcal{H}_y \otimes \dots$, and subscripts A , B , and E are used throughout this work to clarify the subspace to which each expression belongs. Suppose that a density operator $\sigma \in \mathcal{O}(\mathcal{H}_A)$ is a steady state of $\mathcal{F}$, viz.,

$$\boxed{\mathcal{F}\sigma = \sigma.} \quad (2.2)$$

The spectral form of σ is assumed to be

$$\sigma = \sum_n p_n |n\rangle_A \langle n|, \quad (2.3)$$

where $\{p_n : n = 0, \dots, d_A - 1\}$ are the eigenvalues of σ , $\{|n\rangle_A \in \mathcal{H}_A : n = 0, \dots, d_A - 1\}$ is an orthonormal basis of $\mathcal{H}_A$, d_x is the dimension of $\mathcal{H}_x$, and each $|n\rangle_A$ is an eigenvector of σ with eigenvalue p_n . σ is assumed to be full-rank, viz., $p_n > 0$ for all n .

Following Roberts *et al.* [3], assume that $d_B = d_A$ and $|\psi\rangle_{AB}$ is a purification of the steady state σ , given by

$$|\psi\rangle_{AB} = \sum_n \sqrt{p_n} |n\rangle_A \otimes |\tilde{n}\rangle_B, \quad (2.4)$$

where

$$|\tilde{n}\rangle_B = W\theta |n\rangle_A, \quad (2.5)$$

$W : \mathcal{H}_A \rightarrow \mathcal{H}_B$ is a unitary operator, and $\theta : \mathcal{H}_A \rightarrow \mathcal{H}_A$ is an antiunitary operator. The concept of antiunitary operators is reviewed in Appendix A.

Remark 2.1. An antiunitary operator can always be decomposed as $u\vartheta$, where u is a unitary operator and ϑ is a conjugation (antiunitary and $\vartheta^2 = I_A$, where $I_{xy\dots}$ is the identity operator on $\mathcal{H}_x \otimes \mathcal{H}_y \otimes \dots$). As W is left unspecified throughout this work, u may be absorbed into the definition of W , and θ in Eq. (2.5) can be taken as a conjugation without loss of generality.

B. Definition of the reversal condition

Definition 2.1 (Reversal condition). Assuming the model in Sec. 2 A, the whole system is said to obey the reversal condition if there exists a unitary U_E on $\mathcal{H}_E$ such that

$$(I_A \otimes V)(I_{AB} \otimes U_E)(U \otimes I_B) |\psi\rangle_{AB} \otimes |\chi\rangle_E = |\psi\rangle_{AB} \otimes |\tilde{\chi}\rangle_E, \quad (2.6)$$

where $|\tilde{\chi}\rangle_E \in \mathcal{H}_E$ is the final state of the field mode.

Physically, the reversal condition means that system B, as a “reverser,” can undo the entanglement between system A and the field mode, with the help of an intermediate U_E . An equivalent picture is to reverse the arrow of time depicted in Fig. 1 and rewrite Eq. (2.6) as

$$|\psi\rangle_{AB} \otimes |\chi\rangle_E = (U^\dagger \otimes I_B)(I_{AB} \otimes U_E^\dagger)(I_A \otimes V^\dagger) |\psi\rangle_{AB} \otimes |\tilde{\chi}\rangle_E. \quad (2.7)$$

Under this reversed arrow of time, $|\psi\rangle_{AB} \otimes |\tilde{\chi}\rangle_E$ is the initial state, $|\psi\rangle_{AB} \otimes |\chi\rangle_E$ is the final state, and system B is a reverser *in advance* that interacts with the field mode first and prevents the entanglement between system A and the field mode. Either way, system A is always assumed to be given throughout this work, while system B is to be designed as the reverser.

The allowance of an intermediate U_E is a key property that makes the reversal condition different from all previously proposed absorber conditions [1–5], which all assume $U_E \propto I_E$. The reason for introducing U_E is to make the reversal condition general enough to be boiled down to a simple formula in terms of CPTP maps, as shown in Theorem 2.1 later.

The original absorber condition proposed by Stannigel *et al.* [1] assumes that both $|\chi\rangle_E$ and $|\tilde{\chi}\rangle_E$ are the vacuum state of a bosonic mode. System B must then absorb any emission by system A—hence the name absorber. Refs. [1–3, 5] also assume that the system-field interactions are infinitesimally weak so that a continuous-time Markov model becomes valid. No such assumptions are made in Def. 2.1, other than those in Sec. 2 A. As the condition in Def. 2.1 is much more general and no longer restricted to the absorber setting, it is appropriate to give it a different name.

It can be shown that, given the model in Sec. 2 A, a V that satisfies the reversal condition always exists [4, Lemma 4.1]; see also Prop. 4.1 later.

After the interactions with the field mode, systems A and B are assumed, as in previously proposed absorber conditions, to return to the initial state $|\psi\rangle_{AB}$. In other words, $|\psi\rangle_{AB}$ is their steady state after sequential interactions with multiple field modes, each with the same initial state. If systems A and B are not initially in this steady state, they may still converge to it after many rounds of interactions, such that the assumption of $|\psi\rangle_{AB}$ as the initial state becomes valid. The precise condition for the steady-state convergence is, however, outside the scope of this work.

To proceed further, it is vital to define a CPTP map $\mathcal{G} : \mathcal{O}(\mathcal{H}_B) \rightarrow \mathcal{O}(\mathcal{H}_B)$ as

$$\mathcal{G}\rho_B \equiv \text{tr}_E V^\dagger (\rho_B \otimes |\tilde{\chi}\rangle_E \langle \tilde{\chi}|) V. \quad (2.8)$$

Notice the placements of $V^\dagger$ and V . Under the arrow of time depicted in Fig. 1, $\mathcal{G}$ is not a physical channel, but it is a physical channel for system B if the arrow of time is reversed, so that $V^\dagger$ is the Schrödinger-picture unitary and $|\tilde{\chi}\rangle_E$ is the ancilla input state. This definition allows one to express the reversal condition in terms of the $\mathcal{F}$ and $\mathcal{G}$ maps, as shown by Theorem 2.1 later.

C. A precise formula for the reversal condition

I now work towards Theorem 2.1 by presenting a series of lemmas and definitions.

Lemma 2.1. *The reversal condition is satisfied if and only if the $\mathcal{F}$ and $\mathcal{G}$ maps defined by Eqs. (2.1) and (2.8) obey*

$$(\mathcal{F} \otimes \mathcal{I}_B) |\psi\rangle_{AB} \langle\psi| = (\mathcal{I}_A \otimes \mathcal{G}) |\psi\rangle_{AB} \langle\psi|, \quad (2.9)$$

where $\mathcal{I}_{xy\dots}$ is the identity map on $\mathcal{O}(\mathcal{H}_x \otimes \mathcal{H}_y \otimes \dots)$.

Proof. Define

$$|\phi_1\rangle \equiv (U \otimes I_B) |\psi\rangle_{AB} \otimes |\chi\rangle_E, \quad (2.10)$$

$$|\phi_2\rangle \equiv (I_A \otimes V^\dagger) |\psi\rangle_{AB} \otimes |\tilde{\chi}\rangle_E, \quad (2.11)$$

so that

$$(\mathcal{F} \otimes \mathcal{I}_B) |\psi\rangle_{AB} \langle\psi| = \text{tr}_E |\phi_1\rangle \langle\phi_1|, \quad (\mathcal{I}_A \otimes \mathcal{G}) |\psi\rangle_{AB} \langle\psi| = \text{tr}_E |\phi_2\rangle \langle\phi_2|. \quad (2.12)$$

To prove the “only if” part, note that Eq. (2.6) implies

$$|\phi_2\rangle = (I_{AB} \otimes U_E) |\phi_1\rangle, \quad (2.13)$$

which implies Eq. (2.9) via Eqs. (2.12). To prove the “if” part, note that Eq. (2.9) implies

$$\text{tr}_E |\phi_1\rangle \langle\phi_1| = \text{tr}_E |\phi_2\rangle \langle\phi_2| \quad (2.14)$$

via Eqs. (2.12), meaning that $|\phi_1\rangle$ and $|\phi_2\rangle$ are purifications of the same density operator on $\mathcal{H}_A \otimes \mathcal{H}_B$. Then there exists a unitary U_E on $\mathcal{H}_E$ such that [16, Theorem 3.11]

$$|\phi_2\rangle = (I_{AB} \otimes U_E) |\phi_1\rangle, \quad (2.15)$$

and Eq. (2.6) in Def. 2.1 is satisfied. $\square$

To proceed further, it is necessary to establish some linear algebra first.

Definition 2.2 (Hilbert-Schmidt inner product and adjoint). *The Hilbert-Schmidt inner product between two operators X and Y on the same Hilbert space $\mathcal{H}$ is defined as*

$$\langle Y, X \rangle \equiv \text{tr } Y^\dagger X. \quad (2.16)$$

The Hilbert-Schmidt adjoint $\mathcal{M}^{\text{HS}} : \mathcal{O}(\mathcal{H}') \rightarrow \mathcal{O}(\mathcal{H})$ of a map $\mathcal{M} : \mathcal{O}(\mathcal{H}) \rightarrow \mathcal{O}(\mathcal{H}')$ is defined by

$$\langle \mathcal{M}Y, X \rangle = \langle Y, \mathcal{M}^{\text{HS}} X \rangle \quad \forall X, Y. \quad (2.17)$$

Definition 2.3 (Connes inner product [17] and adjoint). *The Connes inner product between operators X and Y with respect to a full-rank density operator ρ , all on the same Hilbert space $\mathcal{H}$, is defined as*

$$\langle Y, X \rangle_\rho \equiv \langle Y, \mathcal{E}_\rho X \rangle = \text{tr } Y^\dagger \mathcal{E}_\rho X, \quad (2.18)$$

where

$$\mathcal{E}_\rho X \equiv \rho^{1/2} X \rho^{1/2} \quad (2.19)$$

is self-adjoint ($\mathcal{E}_\rho = \mathcal{E}_\rho^{\text{HS}}$) and positive-definite with respect to the Hilbert-Schmidt inner product.

Let $\tau \in \mathcal{O}(\mathcal{H}')$ be another full-rank density operator. The adjoint $\mathcal{M}^{\text{Con}} : \mathcal{O}(\mathcal{H}) \rightarrow \mathcal{O}(\mathcal{H}')$ of a map $\mathcal{M} : \mathcal{O}(\mathcal{H}') \rightarrow \mathcal{O}(\mathcal{H})$ with respect to the Connes inner product is defined by

$$\langle \mathcal{M}Y, X \rangle_\rho = \langle Y, \mathcal{M}^{\text{Con}} X \rangle_\tau \quad \forall X \in \mathcal{O}(\mathcal{H}), Y \in \mathcal{O}(\mathcal{H}'). \quad (2.20)$$

Connes introduced this inner product in the context of von Neumann algebra [17, Eq. (1)]. The definition here in terms of the density operator can be found, for example, in Ref. [18, Eq. (8.17)]. It is also called the KMS inner product in the literature for unknown reasons [19]. The Con adjoint is instrumental in the works of Accardi and Cecchini [20] and Petz [15].

Definition 2.4 (Petz recovery map [15, 21]). *Given an initial state $\rho \in \mathcal{O}(\mathcal{H})$, a CPTP map $\mathcal{F} : \mathcal{O}(\mathcal{H}) \rightarrow \mathcal{O}(\mathcal{H}')$, and $\tau = \mathcal{F}\rho$ for the Con adjoint in Def. 2.3,*

$$\mathcal{F}^{\text{Petz}} \equiv \mathcal{F}^{\text{HS Con HS}} \quad (2.21)$$

is called the Petz recovery map. Explicitly,

$$\mathcal{F}^{\text{Petz}} = \mathcal{E}_\rho \mathcal{F}^{\text{HS}} \mathcal{E}_{\mathcal{F}\rho}^{-1}. \quad (2.22)$$

Recall Remark 2.1 stating that θ can always be assumed to be a conjugation here. It follows that the map defined as

$$\Theta X \equiv \theta^{-1} X \theta = \theta X \theta \quad (2.23)$$

is also a conjugation with respect to the Hilbert-Schmidt inner product. Define also the unitary map $\mathcal{W} : \mathcal{O}(\mathcal{H}_A) \rightarrow \mathcal{O}(\mathcal{H}_B)$ as

$$\mathcal{W}X \equiv W X W^\dagger, \quad (2.24)$$

and the adjoint map $\mathcal{J} : \mathcal{O}(\mathcal{H}) \rightarrow \mathcal{O}(\mathcal{H})$ as

$$\mathcal{J}X \equiv X^\dagger. \quad (2.25)$$

These maps will be essential in what follows; their properties are reviewed in Prop. A.2.

Three more lemmas will be needed.

Lemma 2.2. *Given Eq. (2.5),*

$$\langle \tilde{n} |_B X | \tilde{m} \rangle_B = \langle m |_A \mathcal{J} \Theta \mathcal{W}^{-1} X | n \rangle_A. \quad (2.26)$$

Proof. To deal with the antiunitary operator in Eq. (2.5), I switch temporarily from the bracket notation to the proper inner-product notation $\langle \cdot, \cdot \rangle$ and write $|n\rangle_A$ as n_A . The unitarity of W and the conjugation property

of θ lead to

$$\langle \tilde{n}|_B X |\tilde{m}\rangle_B = \langle W\theta n_A, XW\theta m_A \rangle = \langle W^\dagger X^\dagger W\theta n_A, \theta m_A \rangle = \langle m_A, \theta W^\dagger X^\dagger W\theta n_A \rangle \quad (2.27)$$

$$= \langle m|_A \Theta W^{-1} \mathcal{J} X |n\rangle_A. \quad (2.28)$$

Since $\mathcal{J}$ commutes with any unitary or conjugation map by virtue of Prop. A.2, the lemma follows. $\square$

In the following, I always assume a steady state $\mathcal{F}\sigma = \sigma$ for the Connes inner product and adjoint. The following lemma follows Ref. [3] but does not need the bilinear form introduced there.

Lemma 2.3. *For any $X, Y \in \mathcal{O}(\mathcal{H}_A)$,*

$$\text{tr}(X \otimes W\Theta Y) |\psi\rangle_{AB} \langle\psi| = \langle Y, X \rangle_\sigma. \quad (2.29)$$

Proof.

$$\text{tr}(X \otimes W\Theta Y) |\psi\rangle_{AB} \langle\psi| = \sum_{n,m} \sqrt{p_n p_m} \langle n|_A X |m\rangle_A \langle \tilde{n}|_B W\Theta Y |\tilde{m}\rangle_B \quad (\text{by Eq. (2.4)}) \quad (2.30)$$

$$= \sum_{n,m} \sqrt{p_n p_m} \langle n|_A X |m\rangle_A \langle m|_A \mathcal{J} Y |n\rangle_A \quad (\text{by Lemma 2.2}) \quad (2.31)$$

$$= \text{tr} \sigma^{1/2} X \sigma^{1/2} Y^\dagger \quad (\text{by Eq. (2.3)}) \quad (2.32)$$

$$= \langle Y, X \rangle_\sigma. \quad (\text{by Def. 2.3}) \quad (2.33)$$

$\square$

Lemma 2.3 shows the importance of the antiunitary operator introduced in Eq. (2.5)—the right-hand side of Eq. (2.29) is antilinear with respect to Y , so an antilinear map Θ is needed to make the left-hand side antilinear with respect to Y as well, and the presence of Θ here can be traced back to Eq. (2.5) via Lemma 2.2.

Lemma 2.4 (Chain rule).

$$(\mathcal{M}_2 \mathcal{M}_1)^* = \mathcal{M}_1^* \mathcal{M}_2^*, \quad (2.34)$$

where $*$ is HS, Con, or Petz.

All the preceding preparations culminate in the following theorem, which distills the reversal condition into a precise formula in terms of the $\mathcal{F}$ and $\mathcal{G}$ maps, hiding the “gauge freedom” of U_E in the reversal condition.

Theorem 2.1. *The reversal condition is satisfied if and only if the $\mathcal{F}$ and $\mathcal{G}$ maps defined by Eqs. (2.1) and (2.8) obey*

$$\boxed{\mathcal{G} = W\Theta \mathcal{F}^{\text{Petz}} \Theta W^{-1}}. \quad (2.35)$$

Proof. Consider the left-hand side of Eq. (2.9) and write, using Lemma 2.3,

$$\text{tr}(X \otimes W\Theta Y)(\mathcal{F} \otimes \mathcal{I}_B) |\psi\rangle_{AB} \langle\psi| = \text{tr}(\mathcal{F}^{\text{HS}} X \otimes W\Theta Y) |\psi\rangle_{AB} \langle\psi| = \langle Y, \mathcal{F}^{\text{HS}} X \rangle_\sigma. \quad (2.36)$$

The right-hand side of Eq. (2.9) similarly gives

$$\text{tr}(X \otimes W\Theta Y)(\mathcal{I}_A \otimes \mathcal{G}) |\psi\rangle_{AB} \langle\psi| = \langle \Theta W^{-1} \mathcal{G}^{\text{HS}} W\Theta Y, X \rangle_\sigma. \quad (2.37)$$

To prove the “only if” part, observe that the reversal condition implies the equality of Eqs. (2.36) and (2.37) for any X, Y by Lemma 2.1. By the definition of the Con adjoint in Def. 2.3, one obtains

$$\mathcal{F}^{\text{HS Con}} = \Theta \mathcal{W}^{-1} \mathcal{G}^{\text{HS}} \mathcal{W} \Theta. \quad (2.38)$$

Taking the Hilbert-Schmidt adjoint, using the chain rule in Lemma 2.4, noting that $\mathcal{W}^{\text{HS}} = \mathcal{W}^{-1}$ and $\Theta^{\text{HS}} = \Theta$, and applying the definition of the Petz map in Def. 2.4, one obtains

$$\mathcal{F}^{\text{Petz}} = \mathcal{F}^{\text{HS Con HS}} = \Theta \mathcal{W}^{-1} \mathcal{G} \mathcal{W} \Theta, \quad (2.39)$$

which leads to Eq. (2.35).

To prove the “if” part, retrace the preceding steps backwards to go from Eq. (2.35) to

$$\text{tr}(X \otimes \mathcal{W} \Theta Y)(\mathcal{F} \otimes \mathcal{I}_B) |\psi\rangle_{AB} \langle \psi| = \text{tr}(X \otimes \mathcal{W} \Theta Y)(\mathcal{I}_A \otimes \mathcal{G}) |\psi\rangle_{AB} \langle \psi| \quad (2.40)$$

for any $X, Y \in \mathcal{O}(\mathcal{H}_A)$. Now express an arbitrary $Z \in \mathcal{O}(\mathcal{H}_A \otimes \mathcal{H}_B)$ as

$$Z = \sum_{j,k} Z_{jk} a_j \otimes b_k \quad (2.41)$$

in terms of a matrix Z_{jk} , a basis $\{a_j\}$ of $\mathcal{O}(\mathcal{H}_A)$, and a basis $\{b_k\}$ of $\mathcal{O}(\mathcal{H}_B)$. Plug $X = a_j$ and $Y = \Theta \mathcal{W}^{-1} b_k$ into Eq. (2.40) and take the sum $\sum_{j,k} Z_{jk}(\dots)$ to obtain

$$\text{tr} Z(\mathcal{F} \otimes \mathcal{I}_B) |\psi\rangle_{AB} \langle \psi| = \text{tr} Z(\mathcal{I}_A \otimes \mathcal{G}) |\psi\rangle_{AB} \langle \psi| \quad \forall Z \in \mathcal{O}(\mathcal{H}_A \otimes \mathcal{H}_B), \quad (2.42)$$

which is equivalent to Eq. (2.9) and therefore implies the reversal condition by Lemma 2.1. $\square$

Eq. (2.35) in Theorem 2.1 is a necessary and sufficient condition for system B to be a reverser—any reverser must obey Eq. (2.35), and any system B that obeys it is a reverser.

Before closing this section, I give a noteworthy corollary.

Corollary 2.1. *Let*

$$\tilde{\sigma} \equiv \mathcal{W} \Theta \sigma = \text{tr}_A |\psi\rangle_{AB} \langle \psi|. \quad (2.43)$$

Under the reversal condition, $\tilde{\sigma}$ is a steady state of $\mathcal{G}$, viz.,

$$\mathcal{G} \tilde{\sigma} = \tilde{\sigma}. \quad (2.44)$$

Proof. By the recovery property of $\mathcal{F}^{\text{Petz}}$ [15, 21],

$$\mathcal{F}^{\text{Petz}} \sigma = \mathcal{F}^{\text{Petz}} \mathcal{F} \sigma = \sigma. \quad (2.45)$$

Then use Eqs. (2.35), (2.43), and (2.45) to obtain

$$\mathcal{G} \tilde{\sigma} = \mathcal{W} \Theta \mathcal{F}^{\text{Petz}} \Theta \mathcal{W}^{-1} \mathcal{W} \Theta \sigma = \mathcal{W} \Theta \mathcal{F}^{\text{Petz}} \sigma = \mathcal{W} \Theta \sigma = \tilde{\sigma}. \quad (2.46)$$

$\square$

3. DETAILED BALANCE

There exist many quantum generalizations of the detailed balance condition. As discovered by Roberts *et al.* [3], the one most relevant to the absorber theory is the so-called SQDB- θ condition proposed by Fagnola

and Umanità [13], where SQDB stands for standard quantum detailed balance. It turns out that, if system A satisfies the SQDB- θ condition, the reversal condition given by Theorem 2.1 for the whole system can be simplified significantly. Here I define a discrete-time version of the SQDB- θ condition for mathematical simplicity.

Definition 3.1 (Discrete-time SQDB- θ condition). *A CPTP map $\mathcal{F}$ and its steady state σ are said to satisfy the SQDB- θ condition if*

$$\langle \mathcal{F}^{n \text{ HS}} Y, X \rangle_\sigma = \langle \mathcal{F}^{n \text{ HS}} \Theta X, \Theta Y \rangle_\sigma, \quad \forall X, Y \in \mathcal{O}(\mathcal{H}_A), \quad \forall n = 0, 1, 2, \dots \quad (3.1)$$

Physically, $\mathcal{F}^n$ is the channel for system A after it interacts with n field modes sequentially, each with the same initial state $|\chi\rangle_E$. A continuous-time limit can be obtained heuristically by writing

$$\mathcal{F} = \exp(\mathcal{L}dt), \quad t \equiv ndt, \quad \mathcal{F}^n = \exp(\mathcal{L}t), \quad (3.2)$$

where dt is infinitesimal and $\mathcal{L}$ is the generator of the semigroup $\{\exp(\mathcal{L}t) : t \geq 0\}$. I will not, however, consider the continuous-time limit for the rest of this work.

The following theorem originates from Ref. [13]; I provide a proof for completeness.

Theorem 3.1 (Ref. [13]). *The SQDB- θ condition in Def. 3.1 implies each of the following two conditions:*

$$\boxed{\sigma = \Theta\sigma}, \quad (3.3)$$

$$\boxed{\mathcal{F} = \Theta\mathcal{F}^{\text{Petz}}\Theta}. \quad (3.4)$$

Conversely, the two conditions together imply the SQDB- θ condition.

To prove this theorem, I need the following lemma first.

Lemma 3.1. *For any $X, Y \in \mathcal{O}(\mathcal{H}_A)$,*

$$\langle \Theta X, \Theta Y \rangle_\sigma = \langle Y, X \rangle_{\Theta\sigma}, \quad (3.5)$$

$$\langle \mathcal{F}^{n \text{ HS}} \Theta X, \Theta Y \rangle_\sigma = \langle Y, \Theta \mathcal{F}^{n \text{ HS}} \Theta X \rangle_{\Theta\sigma}. \quad (3.6)$$

Proof. To prove Eq. (3.5), use Def. 2.3 and Prop. A.2 to write

$$\langle \Theta X, \Theta Y \rangle_\sigma = \langle \Theta X, \mathcal{E}_\sigma \Theta Y \rangle = \langle \Theta \mathcal{E}_\sigma \Theta Y, X \rangle = \langle \mathcal{E}_{\Theta\sigma} Y, X \rangle = \langle Y, X \rangle_{\Theta\sigma}. \quad (3.7)$$

To obtain Eq. (3.6), replace X in Eq. (3.5) by $\Theta \mathcal{F}^{n \text{ HS}} \Theta X$. $\square$

Proof of Theorem 3.1. First prove the forward direction. To derive Eq. (3.3), combine Eq. (3.1) for $n = 0$ and Eq. (3.5) to obtain

$$\langle Y, X \rangle_\sigma = \langle \Theta X, \Theta Y \rangle_\sigma = \langle Y, X \rangle_{\Theta\sigma}. \quad (3.8)$$

Then plug $Y = I$ to obtain

$$\langle I, X \rangle_\sigma = \text{tr } \sigma X = \langle I, X \rangle_{\Theta\sigma} = \text{tr}(\Theta\sigma)X, \quad (3.9)$$

which holds for any X , leading to $\Theta\sigma = \sigma$.

For $n > 0$, write

$$\langle \mathcal{F}^{n \text{ HS}} Y, X \rangle_\sigma = \langle \mathcal{F}^{n \text{ HS}} \Theta X, \Theta Y \rangle_\sigma \quad (\text{by Eq. (3.1)}) \quad (3.10)$$

$$= \langle Y, \Theta \mathcal{F}^{n \text{ HS}} \Theta X \rangle_\sigma, \quad (\text{by Eq. (3.6) and } \Theta\sigma = \sigma) \quad (3.11)$$

which implies, by the definition of Con in Def. 2.3,

$$\mathcal{F}^{n \text{ HS Con}} = \Theta \mathcal{F}^{n \text{ HS}} \Theta, \quad (3.12)$$

$$\mathcal{F}^{n \text{ HS Con HS}} = \mathcal{F}^{n \text{ Petz}} = \Theta \mathcal{F}^n \Theta, \quad (3.13)$$

giving Eq. (3.4) for $n = 1$.

Now prove the converse. Eq. (3.3) can be plugged into Eq. (3.5) to give Eq. (3.1) for $n = 0$. To derive Eq. (3.1) for $n > 0$, take the n th power of Eq. (3.4) to obtain Eq. (3.13) by the chain rule in Lemma 2.4. Eq. (3.13) is equivalent to Eq. (3.12), which can be plugged into the right-hand side of Eq. (3.6). Plug also $\Theta\sigma = \sigma$ and use the definition of Con to obtain

$$\langle \mathcal{F}^{n \text{ HS}} \Theta X, \Theta Y \rangle_\sigma = \langle Y, \mathcal{F}^{n \text{ HS Con}} X \rangle_\sigma = \langle \mathcal{F}^{n \text{ HS}} Y, X \rangle_\sigma, \quad (3.14)$$

which is Eq. (3.1) for $n > 0$. $\square$

The remarkable simplification of the Petz map under the SQDB- θ condition simplifies the reversal condition as well.

Corollary 3.1. *If system A satisfies Eq. (3.4), the reversal condition is satisfied if and only if*

$$\boxed{\mathcal{G} = \mathcal{W} \mathcal{F} \mathcal{W}^{-1}}. \quad (3.15)$$

Proof. Plug Eq. (3.4) into Eq. (2.35). $\square$

It is interesting to observe that system B mirrors properties of system A under the reversal condition, as shown by Corollary 2.1 and the corollary below.

Corollary 3.2. *If system A satisfies the SQDB- θ condition and the whole system satisfies the reversal condition, then $\mathcal{G}$ and its steady state $\tilde{\sigma}$ also satisfy a SQDB- $\tilde{\theta}$ condition given by*

$$\tilde{\sigma} = \tilde{\Theta} \tilde{\sigma}, \quad (3.16)$$

$$\mathcal{G} = \tilde{\Theta} \mathcal{G}^{\text{Petz}} \tilde{\Theta}, \quad (3.17)$$

where the conjugation $\tilde{\theta}$ on $\mathcal{H}_B$, the conjugation $\tilde{\Theta}$ on $\mathcal{O}(\mathcal{H}_B)$, and $\mathcal{G}^{\text{Petz}}$ are respectively defined by

$$\tilde{\theta} \equiv W \theta W^\dagger, \quad (3.18)$$

$$\tilde{\Theta} X \equiv \tilde{\theta} X \tilde{\theta} = \mathcal{W} \Theta \mathcal{W}^{-1} X, \quad (3.19)$$

$$\mathcal{G}^{\text{Petz}} \equiv \mathcal{E}_{\tilde{\sigma}} \mathcal{G}^{\text{HS}} \mathcal{E}_{\tilde{\sigma}}^{-1} = \mathcal{E}_{\tilde{\sigma}} \mathcal{G}^{\text{HS}} \mathcal{E}_{\tilde{\sigma}}^{-1}. \quad (3.20)$$

Proof. Use Eqs. (3.19), (2.43), and (3.3) to write

$$\tilde{\Theta} \tilde{\sigma} = \mathcal{W} \Theta \mathcal{W}^{-1} \mathcal{W} \Theta \sigma = \mathcal{W} \sigma = \mathcal{W} \Theta \sigma = \tilde{\sigma}. \quad (3.21)$$

One can also show

$$\mathcal{G}^{\text{Petz}} = \mathcal{E}_{\tilde{\sigma}} \mathcal{G}^{\text{HS}} \mathcal{E}_{\tilde{\sigma}}^{-1} = \mathcal{W} \mathcal{E}_{\Theta\sigma} \mathcal{W}^{-1} \mathcal{G}^{\text{HS}} \mathcal{W} \mathcal{E}_{\Theta\sigma}^{-1} \mathcal{W}^{-1} \quad (\text{by Eq. (2.43) and Prop. A.2}) \quad (3.22)$$

$$= \mathcal{W} \mathcal{E}_{\sigma} \mathcal{W}^{-1} \mathcal{G}^{\text{HS}} \mathcal{W} \mathcal{E}_{\sigma}^{-1} \mathcal{W}^{-1} \quad (\text{by Eq. (3.3)}) \quad (3.23)$$

$$= \mathcal{W} \mathcal{E}_{\sigma} \mathcal{F}^{\text{HS}} \mathcal{E}_{\sigma}^{-1} \mathcal{W}^{-1} \quad (\text{by Eq. (3.15)}) \quad (3.24)$$

$$= \mathcal{W} \mathcal{F}^{\text{Petz}} \mathcal{W}^{-1} \quad (\text{by Eq. (2.22) and } \mathcal{F}\sigma = \sigma) \quad (3.25)$$

$$= \mathcal{W} \Theta \mathcal{W}^{-1} \mathcal{G} \mathcal{W} \Theta \mathcal{W}^{-1} \quad (\text{by Eq. (2.35)}) \quad (3.26)$$

$$= \tilde{\Theta} \mathcal{G} \tilde{\Theta}, \quad (\text{by Eq. (3.19)}) \quad (3.27)$$

which leads to Eq. (3.17). $\square$

4. SPECIAL REVERSAL CONDITION

A shortcoming of the reversal condition is that it is too vague about the system-B dynamics V and the intermediate U_E needed to make system B a reverser. Only certain properties of V are specified through the relations between the $\mathcal{F}$ and $\mathcal{G}$ maps, while U_E is left completely unspecified, making the experimental design of the reverser difficult. To overcome the shortcoming, I now focus on a special reversal condition, where U_E is assumed to be the identity and the V that makes system B a reverser can be characterized more explicitly.

Definition 4.1 (Special reversal condition). *The whole system is said to satisfy the special reversal condition if Def. 2.1 is satisfied with $U_E = I_E$, viz.,*

$$\boxed{(I_A \otimes V)(U \otimes I_B) |\psi\rangle_{AB} \otimes |\chi\rangle_E = |\psi\rangle_{AB} \otimes |\tilde{\chi}\rangle_E.} \quad (4.1)$$

This definition, apart from allowing $|\tilde{\chi}\rangle_E$ to be distinct from $|\chi\rangle_E$, is identical to the absorber condition assumed by Godley and Guta in their Lemma 4.1 [4]. They have also proved that there always exists a V that satisfies the condition; I include their result here for completeness.

Proposition 4.1 (Ref. [4, Lemma 4.1]). *A unitary V on $\mathcal{H}_B \otimes \mathcal{H}_E$ that satisfies Eq. (4.1) always exists.*

Proof. Recall the $|\phi_1\rangle$ defined by Eq. (2.10). Since

$$\text{tr}_{BE} |\phi_1\rangle \langle \phi_1| = \mathcal{F}\sigma = \sigma, \quad (4.2)$$

$|\phi_1\rangle$ is a purification of σ . $|\psi\rangle_{AB}$ is also a purification of σ , so the two must be related by an isometry $R : \mathcal{H}_B \rightarrow \mathcal{H}_B \otimes \mathcal{H}_E$ that satisfies $R^\dagger R = I_B$ as follows [16]:

$$|\phi_1\rangle = I_A \otimes R |\psi\rangle_{AB}. \quad (4.3)$$

Now Eq. (4.1) is equivalent to

$$I_A \otimes V |\phi_1\rangle = I_A \otimes V R |\psi\rangle_{AB} = |\psi\rangle_{AB} \otimes |\tilde{\chi}\rangle_E, \quad (4.4)$$

which can be satisfied if

$$V R = |\tilde{\chi}\rangle_E, \quad (4.5)$$

where $|\tilde{\chi}\rangle_E : \mathcal{H}_B \rightarrow \mathcal{H}_B \otimes \mathcal{H}_E$ is a partial ket operator defined by

$$|\tilde{\chi}\rangle_E |\xi\rangle_B \equiv |\xi\rangle_B \otimes |\tilde{\chi}\rangle_E \quad \forall |\xi\rangle_B \in \mathcal{H}_B. \quad (4.6)$$

Eq. (4.5) is equivalent to

$$VR|\tilde{n}\rangle_B = |\tilde{\chi}\rangle_E |\tilde{n}\rangle_B = |\tilde{n}\rangle_B \otimes |\tilde{\chi}\rangle_E, \quad n = 0, \dots, d_B - 1. \quad (4.7)$$

Observe that $\{R|\tilde{n}\rangle_B\}$ is an orthonormal set with d_B elements in $\mathcal{H}_B \otimes \mathcal{H}_E$, and $\{|\tilde{n}\rangle_B \otimes |\tilde{\chi}\rangle_E\}$ is also an orthonormal set with d_B elements in $\mathcal{H}_B \otimes \mathcal{H}_E$. It follows that a unitary V that maps the former set to the latter set, thereby satisfying Eqs. (4.7), (4.5), (4.4), and thus (4.1), always exists. $\square$

Since the dimension of $\mathcal{H}_B \otimes \mathcal{H}_E$ is $d_B d_E$, the requirement on V given by Eq. (4.7) does not uniquely specify it. Theorem 4.1, to be shown later in this section, is a more concrete result, demonstrating that the special reversal condition can be expressed precisely in terms of Kraus operators.

I now prepare for Theorem 4.1 by defining the Kraus operators needed there and presenting a lemma.

Definition 4.2 (Kraus operators). *Define*

$$f_j \equiv \langle j|_E U |\chi\rangle_E \in \mathcal{O}(\mathcal{H}_A), \quad (4.8)$$

$$g_j \equiv \langle j|_E V^\dagger |\tilde{\chi}\rangle_E \in \mathcal{O}(\mathcal{H}_B) \quad (4.9)$$

with respect to the same overcomplete system $\{|j\rangle_E \in \mathcal{H}_E : j = 0, \dots, D_E - 1\}$ of $\mathcal{H}_E$ that satisfies [16, Definition 2.20]

$$\sum_j |j\rangle_E \langle j| = I_E. \quad (4.10)$$

$\{f_j\}$ and $\{g_j\}$ are Kraus operators for the $\mathcal{F}$ and $\mathcal{G}$ maps defined by Eqs. (2.1) and (2.8), respectively, viz.,

$$\mathcal{F}\rho_A = \sum_j f_j \rho_A f_j^\dagger, \quad (4.11)$$

$$\mathcal{G}\rho_B = \sum_j g_j \rho_B g_j^\dagger. \quad (4.12)$$

Note that the overcomplete system $\{|j\rangle_E\}$ need not be orthonormal or even linearly independent—it needs only to satisfy Eq. (4.10). Note also that $|\xi\rangle_E : \mathcal{H}_x \rightarrow \mathcal{H}_x \otimes \mathcal{H}_E$ and its adjoint $\langle \xi|_E : \mathcal{H}_x \otimes \mathcal{H}_E \rightarrow \mathcal{H}_x$ in Eqs. (4.8) and (4.9), where $\mathcal{H}_x$ depends on the context, should be regarded as partial ket and bra operators, as reviewed in Appendix B.

Lemma 4.1 (Ref. [3, Appendix D]).

$$X \otimes I_B |\psi\rangle_{AB} = I_A \otimes Y |\psi\rangle_{AB} \quad (4.13)$$

if and only if

$$Y = \mathcal{W} \mathcal{Q} X, \quad (4.14)$$

where $\mathcal{Q} : \mathcal{O}(\mathcal{H}_A) \rightarrow \mathcal{O}(\mathcal{H}_A)$ is a linear map defined as

$$\boxed{\mathcal{Q} \equiv \Theta \mathcal{J} \Delta_\sigma^{-1/2}}, \quad (4.15)$$

and the so-called modular map Δ_σ is defined as

$$\Delta_\sigma X \equiv \sigma X \sigma^{-1}, \quad (4.16)$$

such that

$$\Delta_\sigma^{-1/2} X = \sigma^{-1/2} X \sigma^{1/2}. \quad (4.17)$$

Proof. To prove the “only if” part, start from Eq. (4.13) and write

$$\sum_n \sqrt{p_n} X |n\rangle_A \otimes |\tilde{n}\rangle_B = \sum_m \sqrt{p_m} |m\rangle_A \otimes Y |\tilde{m}\rangle_B, \quad (\text{by Eq. (2.4)}) \quad (4.18)$$

$$\sqrt{p_n} \langle m|_A X |n\rangle_A = \sqrt{p_m} \langle \tilde{n}|_B Y |\tilde{m}\rangle_B = \sqrt{p_m} \langle m|_A \mathcal{J} \Theta \mathcal{W}^{-1} Y |n\rangle_A, \quad (\text{by Lemma 2.2}) \quad (4.19)$$

$$X \sigma^{1/2} = \sigma^{1/2} \mathcal{J} \Theta \mathcal{W}^{-1} Y, \quad (4.20)$$

which leads to Eq. (4.14). To prove the “if” part, it suffices to show that Eq. (4.14) leads to

$$\langle n|_A \otimes \langle \tilde{m}|_B X \otimes I_B |\psi\rangle_{AB} = \langle n|_A \otimes \langle \tilde{m}|_B I_A \otimes Y |\psi\rangle_{AB} \quad \forall n, m. \quad (4.21)$$

Consider the right-hand side first:

$$\begin{aligned} & \langle n|_A \otimes \langle \tilde{m}|_B I_A \otimes Y |\psi\rangle_{AB} \\ &= \langle n|_A \otimes \langle \tilde{m}|_B I_A \otimes \mathcal{W} \Theta \mathcal{J} \Delta_\sigma^{-1/2} X |\psi\rangle_{AB} \quad (\text{by Eqs. (4.14) and (4.15)}) \end{aligned} \quad (4.22)$$

$$= \langle n|_A \otimes \langle \tilde{m}|_B I_A \otimes \mathcal{W} \Theta \mathcal{J} \Delta_\sigma^{-1/2} X \sum_l \sqrt{p_l} |l\rangle_A \otimes |\tilde{l}\rangle_B \quad (\text{by Eq. (2.4)}) \quad (4.23)$$

$$= \sqrt{p_n} \langle \tilde{m}|_B \mathcal{W} \Theta \mathcal{J} \Delta_\sigma^{-1/2} X |\tilde{n}\rangle_B \quad (4.24)$$

$$= \sqrt{p_n} \langle n|_A \Delta_\sigma^{-1/2} X |m\rangle_A \quad (\text{by Lemma 2.2}) \quad (4.25)$$

$$= \sqrt{p_n} \langle n|_A \sigma^{-1/2} X \sigma^{1/2} |m\rangle_A \quad (\text{by Eq. (4.17)}) \quad (4.26)$$

$$= \sqrt{p_m} \langle n|_A X |m\rangle_A. \quad (\text{by Eq. (2.3)}) \quad (4.27)$$

By similar steps, the left-hand side of Eq. (4.21) is given by

$$\langle n|_A \otimes \langle \tilde{m}|_B X \otimes I_B |\psi\rangle_{AB} = \sqrt{p_m} \langle n|_A X |m\rangle_A, \quad (4.28)$$

which is equal to Eq. (4.27), and the desired equality given by Eq. (4.21) is proved. $\square$

Theorem 4.1. *The special reversal condition is satisfied if and only if the Kraus operators $\{f_j\}$ and $\{g_j\}$ defined in Def. 4.2 are related by*

$$\boxed{g_j = \mathcal{W} \mathcal{Q} f_j}, \quad (4.29)$$

where $\mathcal{Q}$ is the linear map defined by Eq. (4.15). If Eq. (4.29) holds for Kraus operators defined with respect to one overcomplete system $\{|j\rangle_E\}$ as per Def. 4.2, then it holds for Kraus operators in terms of any overcomplete system of $\mathcal{H}_E$.

Proof. To prove the “only if” part, rewrite Eq. (4.1) as

$$U \otimes I_B |\psi\rangle_{AB} \otimes |\chi\rangle_E = I_A \otimes V^\dagger |\psi\rangle_{AB} \otimes |\tilde{\chi}\rangle_E \quad (4.30)$$

and apply $\langle j|_E$ on both sides to obtain

$$f_j \otimes I_B |\psi\rangle_{AB} = I_A \otimes g_j |\psi\rangle_{AB}, \quad (\text{by Def. 4.2}) \quad (4.31)$$

which implies Eq. (4.29) by Lemma 4.1. To prove the “if” part, note that Eq. (4.29) also implies Eq. (4.31)

by Lemma 4.1. Then apply $\sum_j |j\rangle_E$ on both sides of Eq. (4.31) to obtain Eq. (4.30), which is equivalent to the special reversal condition.

To prove the invariance of the condition to the assumed overcomplete system, let $\{f'_j\}$ and $\{g'_j\}$ be the Kraus operators defined with respect to another overcomplete system $\{|j'\rangle_E : j = 0, \dots, D'_E - 1\}$. The new system is related to the old system by

$$\langle j'|_E = \langle j'|_E \sum_k |k\rangle_E \langle k| = \sum_k c_{jk} \langle k|_E, \quad (4.32)$$

where $c_{jk} = \langle j'|_E |k\rangle$, and the Kraus operators are similarly related by

$$f'_j = \sum_k c_{jk} f_k, \quad g'_j = \sum_k c_{jk} g_k. \quad (4.33)$$

Now observe that the map $\mathcal{Q}$ defined by Eq. (4.15) is a linear map, since $\Delta_\sigma^{-1/2}$ is linear while Θ and $\mathcal{J}$ are antilinear. It follows that $\mathcal{W}\mathcal{Q}$ is also linear, and Eq. (4.29) implies

$$g'_j = \sum_k c_{jk} g_k = \sum_k c_{jk} \mathcal{W}\mathcal{Q}f_k = \mathcal{W}\mathcal{Q} \sum_k c_{jk} f_k = \mathcal{W}\mathcal{Q}f'_j, \quad (4.34)$$

which is Eq. (4.29) in terms of the new Kraus operators. $\square$

Eq. (4.29) in Theorem 4.1 is a necessary and sufficient condition for system B to be a special reverser—any special reverser must obey Eq. (4.29), and any system B that obeys it is a special reverser.

Notice that $\{\mathcal{Q}f_j\}$ are a set of Kraus operators for $\Theta\mathcal{F}^{\text{Petz}}\Theta$. It follows that $\{\mathcal{W}\mathcal{Q}f_j\}$ are a set of Kraus operators for $\mathcal{W}\Theta\mathcal{F}^{\text{Petz}}\Theta\mathcal{W}^{-1}$, the right-hand side of Eq. (2.35) in Theorem 2.1. Eq. (2.35) in Theorem 2.1 is an equality between two maps $\mathcal{G}$ and $\mathcal{W}\Theta\mathcal{F}^{\text{Petz}}\Theta\mathcal{W}^{-1}$, implying only that their Kraus operators $\{g_j\}$ and $\{\mathcal{W}\mathcal{Q}f_j\}$ are related by a partially isometric matrix [16]. Theorem 4.1, on the other hand, is a special case of Theorem 2.1, as Eq. (4.29) in Theorem 4.1 is an equality between individual Kraus operators.

An example to illustrate Theorem 4.1 is in order.

Example 4.1. Let a set of Kraus operators for the $\mathcal{F}$ map be

$$f_j \equiv \langle j|_E U |\chi\rangle_E = \chi_j u_j, \quad j = 0, \dots, d_E - 1, \quad (4.35)$$

$$\chi_j \equiv \langle j|\chi\rangle_E, \quad (4.36)$$

where each u_j is a unitary operator on $\mathcal{H}_A$ and $\{|j\rangle_E\}$ is an orthonormal basis of $\mathcal{H}_E$. $\mathcal{F}$ is then a random unitary channel given by

$$\mathcal{F}\rho_A = \sum_j |\chi_j|^2 u_j \rho_A u_j^\dagger. \quad (4.37)$$

For example, such a channel can result from

$$U = \exp[-i(H_A \otimes I_E + X_A \otimes X_E)t], \quad (4.38)$$

$$u_j = \exp[-i(H_A + \lambda_j X_A)t], \quad (4.39)$$

where $H_A, X_A \in \mathcal{O}(\mathcal{H}_A)$ and $X_E \in \mathcal{O}(\mathcal{H}_E)$ are self-adjoint operators, $t \in \mathbb{R}$, each $|j\rangle_E$ is an eigenvector of X_E , and $\lambda_j \in \mathbb{R}$ is the corresponding eigenvalue. Physically, H_A is the internal Hamiltonian of system A and $X_A \otimes X_E$ models the coupling between system A and the field.

Assume

$$\sigma = \frac{I_A}{d_A}, \quad (4.40)$$

which is a steady state of $\mathcal{F}$, and pick an orthonormal basis $\{|n\rangle_A\}$ that obeys

$$\theta |n\rangle_A = |n\rangle_A \quad (4.41)$$

to specify the conjugation θ . It follows that, in terms of the θ eigenbasis,

$$\mathcal{Q}f_j = \chi_j \Theta \mathcal{J} u_j = \chi_j \sum_{n,m} \langle m|_A u_j |n\rangle_A |n\rangle_A \langle m|. \quad (4.42)$$

Notice that $\Theta \mathcal{J}$ has performed the transpose on the matrix of u_j as per Prop. A.2. The special reversal condition given by Eq. (4.29) in Theorem 4.1 becomes

$$g_j \equiv \langle j|_E V^\dagger |\tilde{\chi}\rangle_E = \mathcal{W} \mathcal{Q}f_j = \chi_j \mathcal{W} \Theta \mathcal{J} u_j = \chi_j \sum_{n,m} \langle m|_A u_j |n\rangle_A |\tilde{n}\rangle_B \langle \tilde{m}|. \quad (4.43)$$

Assuming $|\tilde{\chi}\rangle_E = |\chi\rangle_E$, one way of implementing this set of Kraus operators is to make

$$V^\dagger = \sum_j v_j^\dagger \otimes |j\rangle_E \langle j|, \quad (4.44)$$

$$g_j = \chi_j v_j^\dagger, \quad (4.45)$$

$$v_j = \mathcal{W} \Theta u_j = \sum_{n,m} (\langle n|_A u_j |m\rangle_A)^* |\tilde{n}\rangle_B \langle \tilde{m}|. \quad (4.46)$$

For the U and u_j given by Eqs. (4.38) and (4.39), a v_j and a V that satisfy the condition are given by

$$v_j = \exp[-i(H_B + \lambda_j X_B)t], \quad (4.47)$$

$$H_B = -\mathcal{W} \Theta H_A, \quad X_B = -\mathcal{W} \Theta X_A, \quad (4.48)$$

$$V = \exp[-i(H_B \otimes I_E + X_B \otimes X_E)t]. \quad (4.49)$$

The negative signs in Eqs. (4.48) come from the fact that Θ in Eq. (4.46) is antiunitary and there is an i in the exponent of u_j in Eq. (4.39). The idea of using a negative-mass oscillator for backaction-noise cancellation [6–12] can then be seen as a special case when $\Theta H_A = H_A$ and H_B is the negative of H_A (ignoring the mathematical complication of applying the theory here to the infinite-dimensional systems considered in Refs. [6–12]).

I emphasize that any system B that implements the Kraus operators given by Eq. (4.29) is a special reverser, so there is considerable freedom in the system design; Eq. (4.49) is simply an obvious choice here.

Under the special reversal condition, the steady state of systems A and B becomes the maximally entangled state

$$|\psi\rangle_{AB} = \frac{1}{\sqrt{d_A}} \sum_n |n\rangle_A \otimes |\tilde{n}\rangle_B, \quad (4.50)$$

because the system- A steady state given by Eq. (4.40) is completely mixed. The bases $\{|n\rangle_A\}$ and $\{|\tilde{n}\rangle_B = W \theta |n\rangle_A = W |n\rangle_A\}$ are controlled by the chosen θ and W operators and the system- B dynamics based on them.

The SQDB- θ condition discussed in Sec. 3 can also simplify the special reversal condition. I need the

following lemma first.

Lemma 4.2. *If Eq. (3.4) is satisfied, there exists a partially isometric matrix $c \in \mathbb{C}^{D_E \times D_E}$ such that*

$$\mathcal{Q}f_j = \sum_k c_{jk} f_k. \quad (4.51)$$

Furthermore, if the set $\{f_j\}$ is linearly independent, then $\{\mathcal{Q}f_j\}$ is also linearly independent and c is unitary. Conversely, if $\{f_j\}$ satisfies Eq. (4.51) with a unitary c , then Eq. (3.4) holds.

Proof. Eq. (3.4) implies the existence of a partially isometric c that satisfies Eq. (4.51) by Ref. [16, Exercise 6.15]. Now assume that $\{f_j\}$ is linearly independent. The linear independence of $\{\mathcal{Q}f_j\}$ can be proved by contradiction: suppose that $\{\mathcal{Q}f_j\}$ is linearly dependent. Then there exists a nonzero $a \in \mathbb{C}^{D_E}$ such that $\sum_j a_j \mathcal{Q}f_j = 0$. As the $\mathcal{Q}$ defined by Eq. (4.15) is invertible, one can apply $\mathcal{Q}^{-1}$ on both sides and obtain $\sum_j a_j f_j = 0$, which contradicts the linear independence of $\{f_j\}$. By Ref. [16, Exercises 6.14 and 6.15], c is unitary if $\{f_j\}$ and $\{\mathcal{Q}f_j\}$ are both linearly independent.

The converse part is proved as follows:

$$\mathcal{F}\rho_A = \sum_j f_j \rho_A f_j^\dagger \quad (\text{by Eq. (4.11)}) \quad (4.52)$$

$$= \sum_{j,k,l} c_{jk} c_{jl}^* (\mathcal{Q}f_k) \rho_A (\mathcal{Q}f_l)^\dagger \quad (\text{by Eq. (4.51)}) \quad (4.53)$$

$$= \sum_k (\mathcal{Q}f_k) \rho_A (\mathcal{Q}f_k)^\dagger \quad (\text{isometry of } c) \quad (4.54)$$

$$= \Theta \mathcal{F}^{\text{Petz}} \Theta \rho_A. \quad (4.55)$$

□

The matrix c in Lemma 4.2 needs to be solved on a case-by-case basis using more details about system A, but once it has been found, it can be used to simplify Theorem 4.1.

Corollary 4.1. *Suppose that the Kraus operators of the system-A channel obey Eq. (4.51) for a certain matrix c . Then the special reversal condition is satisfied if and only if*

$$g_j = \sum_k c_{jk} \mathcal{W}f_k. \quad (4.56)$$

Proof. Plug Eq. (4.51) into Eq. (4.29). □

5. CONCLUSION

This work establishes a rigorous theory of quantum reversal by generalizing the absorber concept and boiling the reversal conditions down to concise formulas. For future work, it will be important to work out more examples, explore applications, and study the effect of decoherence. Of particular interest is the application of the formalism here to the design of time-reversal-based measurements for quantum metrology, a problem that has attracted widespread attention [4–12, 22–31].

Appendix A: Antiunitary operators and maps

For clarity, the appendices use the proper notation of an inner product $\langle \phi, \psi \rangle$ between two elements ϕ and ψ in a Hilbert space $\mathcal{H}$. The inner product is assumed to be antilinear with respect to the first argument and linear with respect to the second argument.

An operator $X : \mathcal{H} \rightarrow \mathcal{H}$ is said to be antilinear if

$$X(\alpha\psi + \beta\phi) = \alpha^* X\psi + \beta^* X\phi \quad \forall \psi, \phi \in \mathcal{H}, \forall \alpha, \beta \in \mathbb{C}. \quad (\text{A1})$$

Denote the set of antilinear operators on $\mathcal{H}$ as $\tilde{\mathcal{O}}(\mathcal{H})$. The adjoint $X^\dagger$ of an antilinear operator $X \in \tilde{\mathcal{O}}(\mathcal{H})$ is defined by

$$\langle \phi, X\psi \rangle = \langle \psi, X^\dagger \phi \rangle \quad \forall \phi, \psi \in \mathcal{H}. \quad (\text{A2})$$

$X^\dagger$ is also antilinear and $X^{\dagger\dagger} = X$. The inverse X^{-1} of an antilinear operator X is defined by

$$X^{-1}X = XX^{-1} = I, \quad (\text{A3})$$

where I is the identity operator on $\mathcal{H}$. X^{-1} , if it exists, is antilinear.

An operator $T \in \tilde{\mathcal{O}}(\mathcal{H})$ is said to be antiunitary if it obeys

$$\langle T\phi, T\psi \rangle = \langle \psi, \phi \rangle \quad \forall \phi, \psi. \quad (\text{A4})$$

If $T^2 = I$ in addition, then T is called a conjugation. I collect some basic facts about antiunitary operators in the following proposition; see, for example, Ref. [14].

Proposition A.1. *An antiunitary operator T has the following properties.*

1. $T^\dagger = T^{-1}$, which is antiunitary.
2. Given an orthonormal set $\{e_j\}$ in $\mathcal{H}$, $\{Te_j\}$ is another orthonormal set.
3. T can always be decomposed as

$$T = u\theta, \quad (\text{A5})$$

where u is unitary and θ is a conjugation. For a conjugation, there exists a unique orthonormal basis $\{e_j\}$ of $\mathcal{H}$ such that

$$\theta e_j = e_j. \quad (\text{A6})$$

It follows that

$$\theta^\dagger = \theta^{-1} = \theta, \quad T^\dagger = T^{-1} = \theta u^\dagger. \quad (\text{A7})$$

The inverse $\mathcal{A}^{-1}$ and the Hilbert-Schmidt adjoint $\mathcal{A}^{\text{HS}}$ of an antilinear map $\mathcal{A}$ are defined in the same manner as those of an antilinear operator. I collect some basic facts about unitary and antiunitary maps in the following proposition.

Proposition A.2. *Define the $\mathcal{J}$, Θ , and $\mathcal{U}$ maps on $\mathcal{O}(\mathcal{H})$ as*

$$\mathcal{J}X \equiv X^\dagger, \quad \Theta X \equiv \theta X \theta, \quad \mathcal{U}X \equiv UXU^\dagger, \quad (\text{A8})$$

where U is an arbitrary unitary operator on $\mathcal{H}$ and θ is an arbitrary conjugation on $\mathcal{H}$.

1. *Commutation with $\mathcal{J}$:*

$$\mathcal{J}\Theta = \Theta\mathcal{J}, \quad \mathcal{J}\mathcal{U} = \mathcal{U}\mathcal{J}. \quad (\text{A9})$$

2. *Chain rules: for any $X, Y \in \mathcal{O}(\mathcal{H})$,*

$$\mathcal{J}(XY) = (\mathcal{J}Y)(\mathcal{J}X), \quad \Theta(XY) = (\Theta X)(\Theta Y), \quad \mathcal{U}(XY) = (\mathcal{U}X)(\mathcal{U}Y). \quad (\text{A10})$$

3. *In terms of the Hilbert-Schmidt inner product, $\mathcal{U}$ is unitary, while $\mathcal{J}$ and Θ are antiunitary, viz., for any $X, Y \in \mathcal{O}(\mathcal{H})$,*

$$\langle \mathcal{J}X, \mathcal{J}Y \rangle = \langle Y, X \rangle, \quad \langle \Theta X, \Theta Y \rangle = \langle Y, X \rangle, \quad \langle \mathcal{U}X, \mathcal{U}Y \rangle = \langle X, Y \rangle. \quad (\text{A11})$$

It follows that

$$\mathcal{J}^{\text{HS}} = \mathcal{J}^{-1} = \mathcal{J}, \quad \Theta^{\text{HS}} = \Theta^{-1} = \Theta, \quad \mathcal{U}^{\text{HS}} = \mathcal{U}^{-1}. \quad (\text{A12})$$

4. *A map in product form*

$$\mathcal{M}_{A,B}X \equiv AXB \quad (\text{A13})$$

obeys

$$\mathcal{M}_{A,B}^{\text{HS}} = \mathcal{M}_{\mathcal{J}A, \mathcal{J}B}, \quad \Theta \mathcal{M}_{A,B} \Theta^{-1} = \mathcal{M}_{\Theta A, \Theta B}, \quad \mathcal{U} \mathcal{M}_{A,B} \mathcal{U}^{-1} = \mathcal{M}_{\mathcal{U}A, \mathcal{U}B}. \quad (\text{A14})$$

5. *Let $\{e_j\}$ be the eigenbasis of θ satisfying Eq. (A6) and let the matrix representation of $X \in \mathcal{O}(\mathcal{H})$ in this basis be*

$$X_{jk} \equiv \langle e_j, X e_k \rangle. \quad (\text{A15})$$

Then

$$\langle e_j, \mathcal{J}X e_k \rangle = X_{kj}^*, \quad \langle e_j, \Theta X e_k \rangle = X_{jk}^*, \quad \langle e_j, \Theta \mathcal{J}X e_k \rangle = X_{kj}, \quad (\text{A16})$$

where $$ denotes the entry-wise complex conjugate.*

6. *Let X be a normal operator and $s \in \mathbb{C}$. Then*

$$\mathcal{J}(X^s) = (\mathcal{J}X)^{s^*}, \quad \Theta(X^s) = (\Theta X)^{s^*}, \quad \mathcal{U}(X^s) = (\mathcal{U}X)^s. \quad (\text{A17})$$

Appendix B: Partial ket and bra operators

Consider two Hilbert spaces $\mathcal{H}_x$ and $\mathcal{H}_y$ and their tensor product $\mathcal{H}_x \otimes \mathcal{H}_y$. I continue to use the proper notation for the inner product and use the bra and ket notations only to denote the operators defined in the following. A partial ket operator $|\xi\rangle_y : \mathcal{H}_x \rightarrow \mathcal{H}_x \otimes \mathcal{H}_y$, where $\xi \in \mathcal{H}_y$, is defined by

$$|\xi\rangle_y \psi \equiv \psi \otimes \xi \quad \forall \psi \in \mathcal{H}_x. \quad (\text{B1})$$

Its adjoint, denoted as $\langle \xi |_y : \mathcal{H}_x \otimes \mathcal{H}_y \rightarrow \mathcal{H}_x$, is defined by

$$\langle \phi, |\xi\rangle_y \psi \rangle = \langle \langle \xi |_y \phi, \psi \rangle \rangle \quad \forall \psi \in \mathcal{H}_x, \phi \in \mathcal{H}_x \otimes \mathcal{H}_y. \quad (\text{B2})$$

I collect some basic facts about the partial ket and bra operators in the following proposition.

Proposition B.1. *Let ξ and η be arbitrary elements of $\mathcal{H}_y$.*

1. $\langle \eta |_y |\xi\rangle_y = \langle \eta, \xi \rangle I_x$.
2. Suppose that $\langle \xi, \xi \rangle = 1$. The operator $|\xi\rangle_y \langle \xi |_y : \mathcal{H}_x \otimes \mathcal{H}_y \rightarrow \mathcal{H}_x \otimes \mathcal{H}_y$ is a projection of $\mathcal{H}_x \otimes \mathcal{H}_y$ onto the subspace

$$|\xi\rangle_y \mathcal{H}_x \equiv \{ \psi \otimes \xi : \psi \in \mathcal{H}_x \}. \quad (\text{B3})$$

3. If $\{\xi_j\}$ is an overcomplete system of $\mathcal{H}_y$ such that $\sum_j |\xi_j\rangle \langle \xi_j| = I_y$, viz.,

$$\psi = \sum_j \xi_j \langle \xi_j, \psi \rangle \quad \forall \psi \in \mathcal{H}_y, \quad (\text{B4})$$

then

$$\sum_j |\xi_j\rangle_y \langle \xi_j |_y = I_x \otimes I_y. \quad (\text{B5})$$

4. For any $X \in \mathcal{O}(\mathcal{H}_x)$,

$$|\xi\rangle_y X = (X \otimes I_y) |\xi\rangle_y, \quad X \langle \xi |_y = \langle \xi |_y (X \otimes I_y). \quad (\text{B6})$$

5. For any $X \in \mathcal{O}(\mathcal{H}_x \otimes \mathcal{H}_y)$ and any overcomplete system $\{\xi_j\}$ of $\mathcal{H}_y$,

$$\text{tr}_y X = \sum_j \langle \xi_j |_y X |\xi_j\rangle_y. \quad (\text{B7})$$

Proof. Let ψ, ϕ be arbitrary elements of $\mathcal{H}_x$ and let $\{a_j\}$, $\{b_k\}$, and $\{a_j \otimes b_k\}$ be orthonormal bases of $\mathcal{H}_x$, $\mathcal{H}_y$, and $\mathcal{H}_x \otimes \mathcal{H}_y$, respectively.

- 1.

$$\langle \phi, \langle \eta |_y |\xi\rangle_y \psi \rangle = \langle \phi \otimes \eta, \psi \otimes \xi \rangle = \langle \phi, \psi \rangle \langle \eta, \xi \rangle. \quad (\text{B8})$$

2. $|\xi\rangle_y \langle \xi |_y$ is obviously self-adjoint. It is also idempotent because $|\xi\rangle_y \langle \xi |_y |\xi\rangle_y \langle \xi |_y = |\xi\rangle_y \langle \xi |_y$. It follows that $|\xi\rangle_y \langle \xi |_y$ is a projection operator. Now let $\mathcal{H}_\xi \subseteq \mathcal{H}_x \otimes \mathcal{H}_y$ be the range of $|\xi\rangle_y \langle \xi |_y$.

Let Ψ be an arbitrary element of $\mathcal{H}_x \otimes \mathcal{H}_y$ and observe that $|\xi\rangle_y \langle \xi|_y \Psi \in |\xi\rangle_y \mathcal{H}_x$, which implies $\mathcal{H}_\xi \subseteq |\xi\rangle_y \mathcal{H}_x$. Conversely, write an arbitrary element of $|\xi\rangle_y \mathcal{H}_x$ as $|\xi\rangle_y \psi$. Then

$$|\xi\rangle_y \langle \xi|_y |\xi\rangle_y \psi = |\xi\rangle_y \langle \xi, \xi \rangle \psi = |\xi\rangle_y \psi, \quad (\text{B9})$$

implying that $|\xi\rangle_y \mathcal{H}_x \subseteq \mathcal{H}_\xi$. Hence $\mathcal{H}_\xi = |\xi\rangle_y \mathcal{H}_x$.

3. Write $\psi = \sum_{k,l} \psi_{kl}(a_k \otimes b_l)$ and $\phi = \sum_{m,n} \phi_{mn}(a_m \otimes b_n)$. Then

$$\sum_j \langle \phi, |\xi_j\rangle_y \langle \xi_j|_y \psi \rangle = \sum_{j,m,n,k,l} \phi_{mn}^* \psi_{kl} \langle a_m \otimes b_n, |\xi_j\rangle_y \langle \xi_j|_y a_k \otimes b_l \rangle \quad (\text{B10})$$

$$= \sum_{j,m,n,k,l} \phi_{mn}^* \psi_{kl} \langle b_n, \xi_j \rangle \langle \xi_j, b_l \rangle \langle a_m, a_k \rangle \quad (\text{B11})$$

$$= \sum_{m,n,k,l} \phi_{mn}^* \psi_{kl} \langle b_n, b_l \rangle \langle a_m, a_k \rangle \quad (\text{B12})$$

$$= \sum_{m,n} \phi_{mn}^* \psi_{mn} = \langle \phi, \psi \rangle. \quad (\text{B13})$$

4.

$$(X \otimes I_y) |\xi\rangle_y \psi = (X \otimes I_y)(\psi \otimes \xi) = (X\psi \otimes \xi) = |\xi\rangle_y X\psi. \quad (\text{B14})$$

5. Let Y be an arbitrary element of $\mathcal{O}(\mathcal{H}_x)$.

$$\sum_j \text{tr} \langle \xi_j|_y X |\xi_j\rangle_y Y = \sum_{j,k} \langle a_k, \langle \xi_j|_y X |\xi_j\rangle_y Y a_k \rangle \quad (\text{B15})$$

$$= \sum_{j,k} \langle a_k \otimes \xi_j, X(Y a_k \otimes \xi_j) \rangle \quad (\text{B16})$$

$$= \sum_{j,k} \langle a_k \otimes \xi_j, X(Y \otimes I_y)(a_k \otimes \xi_j) \rangle \quad (\text{B17})$$

$$= \text{tr} X(Y \otimes I_y) = \text{tr}(\text{tr}_y X)Y. \quad (\text{B18})$$
