# EXTREMES OF GENERALIZED INVERSIONS AND DESCENTS ON PERMUTATION GROUPS 

PHILIP DÖRR

#### Abstract

The classical inversion statistic on symmetric groups is the sum of all indicators $1\{\pi(i)>\pi(j)\}$ for a random permutation $\pi=(\pi(1), \ldots, \pi(n))$ and the pairs $(i, j)$ with $1 \leq i<j \leq n$. The descent statistic counts all $i \in\{1, \ldots, n-1\}$ with $\pi(i)>\pi(i+1)$. The number of inversions can be generalized by restricting the indicators to pairs $(i, j)$ with $i<j$ and $|i-j| \leq d$ for some $d \in\{1, \ldots, n-1\}$. Likewise, the number of descents can be generalized by counting all $i \in\{1, \ldots, n-d\}$ with $\pi(i)>\pi(i+d)$. These generalized statistics can be further extended to the signed and even-signed permutation groups. The bandwidth index $d$ can be chosen in dependence of $n$, and the magnitude of $d$ is significant for asymptotic considerations. It is known that each of these statistics is asymptotically normal for suitable choices of $d$. In this paper we prove the bivariate asymptotic normality and determine the extreme value asymptotics of generalized inversions and descents.

## 1. Introduction

The numbers of inversions and descents are two important quantities of permutations. For a permutation $\pi:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$, an inversion is a pair $(i, j)$ with $i<j$, but $\pi(i)>\pi(j)$. A descent is an index $i$ with $\pi(i)>\pi(i+1)$, i.e., descents correspond to adjacent inversions. We now equip the symmetric group $S_{n}$ with the discrete uniform probability measure induced by the point masses $\mathbb{P}(\{\pi\})=1 / n!\forall \pi \in S_{n}$. In this context, we denote the random numbers of inversions and descents as $X_{\text {inv }}$ and $X_{\text {des }}$. These random variables can also be represented with help of i.i.d. standard uniform variables $Z_{1}, Z_{2}, \ldots, \sim U(0,1)$, namely,

$$
\begin{align*}
& X_{\mathrm{inv}}=\sum_{1 \leq i<j \leq n} 1\left\{Z_{i}>Z_{j}\right\},  \tag{1}\\
& X_{\mathrm{des}}=\sum_{i=1}^{n-1} 1\left\{Z_{i}>Z_{i+1}\right\} .
\end{align*}
$$

In (1), we have to sum the indicators $\mathbf{1}\left\{Z_{i}>Z_{j}\right\}$ over all pairs $(i, j)$ with $i<j$. A class of generalized inversion statistics can be constructed by restricting the sum

[^0]in (1) to pairs $(i, j)$ with $1 \leq j-i \leq d$, for some $d \in\{1, \ldots, n-1\}$. Writing $\mathfrak{N}_{n, d}:=\left\{(i, j) \in\{1, \ldots, n\}^{2} \mid 1<j-i \leq d\right\}$, we can state that
\[

$$
\begin{equation*}
X_{\mathrm{inv}}^{(d)}:=\sum_{(i, j) \in \mathfrak{N}_{n, d}} 1\left\{Z_{i}>Z_{j}\right\} \tag{2}
\end{equation*}
$$

\]

counts the so-called d-inversions. The term generalized inversions is an umbrella term for all $d$-inversions. By choosing $d=n-1$ or $d=1$, it is seen that this class includes common inversions and descents. Moreover, $d$-descents or generalized descents are given by

$$
\begin{equation*}
X_{\mathrm{des}}^{(d)}:=\sum_{i=1}^{n-d} 1\left\{Z_{i}>Z_{i+d}\right\} . \tag{3}
\end{equation*}
$$

Generalized inversions were first introduced by de Mari \& Shayman [5] to solve a problem in algebraic geometry. The first stochastic considerations for the random variables $X_{\text {inv }}^{(d)}$ are due to Bona [2] and Pike [10], who computed the mean and variance and proved a central limit theorem (CLT).

Symmetric groups belong to the class of finite irreducible Coxeter groups, which have been classified by [4]. The concept of inversions and descents can be transferred to these groups, see [1, Section 1.4]. Two other important subfamilies of the finite irreducible Coxeter groups are the signed permutation groups $B_{n}$ and the even-signed permutation groups $D_{n}$. The group $B_{n}$ consists of all maps $\pi$ : $\{1, \ldots, n\} \longrightarrow\{1, \ldots, n\} \cup$ $\{-1, \ldots,-n\}$ for which $|\pi|$ is a permutation. Such a map is called a signed permutation. The groups $D_{n}$ are the subgroups of $B_{n}$ containing all signed permutations with an even number of negative signs. The random number of inversions on these groups can be represented with help of i.i.d. variables $Z_{1}, \ldots, Z_{n} \sim U(-1,1)$ as follows:

$$
\begin{align*}
& X_{\mathrm{inv}}^{B}=\sum_{1 \leq i<j \leq n} 1\left\{Z_{i}>Z_{j}\right\}+\sum_{1 \leq i<j \leq n} 1\left\{-Z_{i}>Z_{j}\right\}+\sum_{i=1}^{n} 1\left\{Z_{i}<0\right\},  \tag{4a}\\
& X_{\mathrm{inv}}^{D}=\sum_{1 \leq i<j \leq n} 1\left\{Z_{i}>Z_{j}\right\}+\sum_{1 \leq i<j \leq n} 1\left\{-Z_{i}>Z_{j}\right\} . \tag{4b}
\end{align*}
$$

We refer to the three families $S_{n}, B_{n}$, and $D_{n}$ as the classical Weyl groups. Recently, Meier \& Stump [9] extended the concept of generalized inversions and descents to the groups $B_{n}$ and $D_{n}$, again proving a CLT.

The investigation of extreme value asymptotics for common inversions and descents was initiated in $[7,6]$, so we aim to extend this knowledge to generalized inversions. We aim to prove Gumbel attraction for both the stand-alone statistics $X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}$ and the joint statistic $\left(X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}\right)^{\top}$. Here, $d_{1}$ and $d_{2}$ can be either fixed or dependent on $n$. We will investigate the impact of the choice of $d$ for these results.

This paper is structured as follows. Section 2 gives basic properties on generalized inversions and descents, and introduces Hájek projections that are used as independent sum approximations. Section 3 deduces the bivariate CLT and the extreme value
theorems for generalized inversions and descents. Section 4 gives the proofs of two auxiliary lemmas determining the choices of $d$ for which the Hájek projection serves as a working approximation. We use typical Landau notation for positive sequences $a_{n}, b_{n}$ as follows:

- $a_{n}=O\left(b_{n}\right)$ means that $\limsup _{n \rightarrow \infty} a_{n} / b_{n}<\infty$.
- $a_{n}=o\left(b_{n}\right)$ means that $\lim _{n \rightarrow \infty} a_{n} / b_{n}=0$. This is also written as $a_{n} \ll b_{n}$ or $b_{n} \gg a_{n}$.
- $a_{n}=\Theta\left(b_{n}\right)$ means that $a_{n}$ and $b_{n}$ have the same order of magnitude, i.e., both $a_{n}=O\left(b_{n}\right)$ and $b_{n}=O\left(a_{n}\right)$ hold.
- $a_{n}=b_{n}+o_{\mathbb{P}}(1)$ means that $a_{n}, b_{n}$ are sequences of random variables with $a_{n}-b_{n} \xrightarrow{\mathbb{P}} 0$.

## 2. BASIC DEFINITIONS

Definition 2.1. Let $S_{n}$ be a symmetric group and let $\pi \in S_{n}$. For $d \in\{1, \ldots, n-1\}$, $d$-inversions are all pairs $(i, j)$ in $\mathfrak{N}_{n, d}$ with $\pi(i)>\pi(j)$. In this sense, common descents equal 1-inversions, and common inversions equal ( $n-1$ )-inversions. Moreover, $d$-descents are all numbers $i \in\{1, \ldots, n-d\}$ with $\pi(i)>\pi(i+d)$. We write $X_{\text {inv }}^{(d)}$ for the random number of $d$-inversions and $X_{\text {des }}^{(d)}$ for the number of $d$-descents. Probabilistic representations are given in (2), (3). ${ }^{1}$

Remark 2.2. Obviously, every number $k \in\{1, \ldots, n\}$ can appear in at most $2 d$ $d$-inversions. This bound is redundant if $d>n / 2$. In fact, it is an important case distinction whether $d \leq n / 2$ or $d>n / 2$, e.g., when calculating the mean and variance of $X_{\text {inv }}^{(d)}$ and $X_{\text {des }}^{(d)}$. In the case of $d \leq n / 2$, we can split $\{1, \ldots, n\}$ into the regions

$$
K_{1}:=\{1, \ldots, d\}, \quad K_{2}:=\{d+1, \ldots, n-d\}, \quad K_{3}:=\{n-d+1, \ldots, n\} .
$$

For each $k \in K_{2}$, all larger indices $k+1, \ldots, k+d$ and all smaller indices $k-1, \ldots, k-d$ allow to form $d$-inversions. For any $k \notin K_{2}$, there are less than $d$ indices available in one direction. If $k \in K_{1}$, then $k-1$ smaller indices are available for $d$-inversions, which is less than $d$ numbers. If $k>n-d$ is large, then there are only $n-k<d$ larger indices available.

On the contrary, if $d>n / 2$, then $n-d<d$ and the above partition into three regions is now written as

$$
K_{1}:=\{1, \ldots, n-d\}, \quad K_{2}:=\{n-d+1, \ldots, d\}, \quad K_{3}:=\{d+1, \ldots, n\} .
$$

Now, if $k \in K_{2}$, then there are only $k-1$ smaller indices and $n-k$ larger indices available to form $d$-inversions.

[^1]The mean and variance of $X_{\mathrm{inv}}^{(d)}$ have been extensively computed by Pike [10]. It is easy to verify that the special cases $d=1$ and $d=n-1$ are consistent with [8, Corollaries 3.2 and 4.2]. The proof of [10, Theorem 1] is reviewed in [9, Theorem A.1], where the variance of $d$-descents is provided as well.

Theorem 2.3 (see [10], Theorem 1 and [9], Theorem A.1). For all $d=1, \ldots, n-1$, it holds that

$$
\mathbb{E}\left(X_{\mathrm{inv}}^{(d)}\right)=\frac{2 n d-d^{2}-d}{4}, \quad \mathbb{E}\left(X_{\mathrm{des}}^{(d)}\right)=\frac{n-d}{2}
$$

Moreover, if $d \leq n / 2$, then

$$
\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)=\frac{6 n d+4 d^{3}+3 d^{2}-d}{72}, \quad \operatorname{Var}\left(X_{\text {des }}^{(d)}\right)=\frac{n+d}{12}
$$

If $d>n / 2$, then

$$
\operatorname{Var}\left(X_{\mathrm{inv}}^{(d)}\right)=-\frac{1}{6} d^{3}+\left(\frac{1}{3} n-\frac{7}{24}\right) d^{2}-\left(\frac{1}{6} n^{2}-\frac{5}{12} n+\frac{1}{8}\right) d+\frac{1}{36} n^{3}-\frac{1}{12} n^{2}+\frac{1}{18} n
$$

and $\operatorname{Var}\left(X_{\text {des }}^{(d)}\right)=(n-d) / 4$.
Meier \& Stump [9] introduced an extension of generalized inversions and descents from symmetric groups to the other classical Weyl groups $B_{n}$ and $D_{n}$. This extension is based on the root poset of a classical Weyl group. We refer to [9, Section 2] for the details. On the symmetric group $S_{n}$, the ordered pairs of indices $(i, j)$ correspond to the positive roots $[i j]:=e_{i}-e_{j}$, where $e_{i}, e_{j}$ are unit vectors in $\mathbb{R}^{n}$, and the height of [ij] within the root poset is $\operatorname{ht}([i j])=j-i$.

On the signed permutation group $B_{n}$, we also have to consider the positive roots $[\widetilde{i j}]:=e_{i}+e_{j}$ and $[i]:=e_{i}$ for $1 \leq i<j \leq n$. The heights of these additional roots are $\operatorname{ht}([\widetilde{i j}])=i+j$ and $\operatorname{ht}([i])=i$. The root $[\widetilde{i j}]$ corresponds to the indicator $\mathbf{1}\{-\pi(i)>\pi(j)\}$ appearing in (4a), while $[i]$ corresponds to $\mathbf{1}\{\pi(i)<0\}$. See [9, Example 2.2] for an illustration of the root poset of $B_{n}$. On the even-signed permutation group $D_{n}$, the roots [ $\left.i\right]$ are disregarded, and $[\widetilde{i j}]$ has height $i+j-2$.
Definition 2.4. For any classical Weyl group, $d$-inversions are determined by roots of height at most $d$, and $d$-descents are determined by roots of height exactly $d$, see [9, Definition 2.4]. For symmetric groups, this coincides with Definition 2.7. In addition to $\mathfrak{N}_{n, d}$, we introduce

$$
\widetilde{\mathfrak{N}}_{n, d}:=\left\{(i, j) \in\{1, \ldots, n\}^{2} \mid i<j, j+i \leq d\right\} .
$$

Then, on the signed and even-signed permutation groups, $X_{\text {inv }}^{(d)}$ and $X_{\text {des }}^{(d)}$ can be expressed as follows:

$$
\begin{equation*}
X_{\mathrm{inv}}^{B,(d)}=\sum_{(i, j) \in \mathfrak{N}_{n, d}} 1\left\{Z_{i}>Z_{j}\right\}+\sum_{(i, j) \in \widetilde{\mathfrak{N}}_{n, d}} 1\left\{-Z_{i}>Z_{j}\right\}+\sum_{i=1}^{d} 1\left\{Z_{i}<0\right\} \tag{5a}
\end{equation*}
$$

$$
\begin{align*}
X_{\text {inv }}^{D,(d)} & =\sum_{(i, j) \in \mathfrak{N}_{n, d}} 1\left\{Z_{i}>Z_{j}\right\}+\sum_{(i, j) \in \tilde{\mathfrak{N}}_{n, d+2}} 1\left\{-Z_{i}>Z_{j}\right\}  \tag{5b}\\
X_{\text {des }}^{B,(d)} & =\sum_{i=1}^{n-d} 1\left\{Z_{i}>Z_{i+d}\right\}+\sum_{i=1}^{\lceil d / 2\rceil-1} 1\left\{-Z_{i}>Z_{d-i}\right\}+1\{\pi(i)>d\}  \tag{5c}\\
X_{\text {des }}^{D,(d)} & =\sum_{i=1}^{n-d} 1\left\{Z_{i}>Z_{i+d}\right\}+\sum_{i=1}^{\lceil d / 2\rceil} 1\left\{-Z_{i}>Z_{d+2-i}\right\} . \tag{5~d}
\end{align*}
$$

Remark 2.5. The largest possible choice of $d$ equals the total height of the root poset, namely, $d_{\max }-1$, where $d_{\max }$ denotes the largest degree of the underlying classical Weyl group. In particular, $d_{\max }=n$ for $S_{n}, d_{\max }=2 n$ for $B_{n}$ and $d_{\max }=2 n-2$ for $D_{n}$. To precisely compute the variance of $X_{\text {inv }}^{(d)}$ and $X_{\text {des }}^{(d)}$ on the groups $B_{n}$ and $D_{n}$, one needs to distinguish eight cases, as seen in [9, Theorems A. 4 and A.13]. However, many of these cases give the same asymptotic quantification, which can be stated as follows:
Lemma 2.6 (cf. [9], Theorems A. 4 and A.13). For the generalized inversions and descents on both the groups $B_{n}$ and $D_{n}$, it holds that

$$
\begin{aligned}
& \operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)= \begin{cases}\frac{1}{36} d^{3}+\frac{1}{12} n d+O\left(d^{2}\right), & d \leq n / 2 \\
\frac{1}{36} d^{3}+O\left(d^{2}\right), & n / 2 \leq d<n, \\
-\frac{1}{12} d^{3}+\frac{1}{3} n d^{2}-\frac{1}{3} n^{2} d+\frac{1}{9} n^{3}+O\left(d^{2}\right), & d \geq n\end{cases} \\
& \operatorname{Var}\left(X_{\text {des }}^{(d)}\right)
\end{aligned}=\left\{\begin{array}{ll}
\frac{1}{24} d+\frac{1}{12} n+O(1), & d<n \\
-\frac{1}{8} d+\frac{1}{4} n+O(1), & d \geq n
\end{array} .\right.
$$

An evident issue seen in (2), (5a), and (5b) is the mutual dependence of the indicators $1\left\{Z_{i}>Z_{j}\right\}$ and $1\left\{-Z_{i}>Z_{j}\right\}$. Therefore, we aim to approximate $X_{\text {inv }}^{(d)}$ with a sum of independent variables. Hájek projections are a common tool for this.
Definition 2.7. Let $Z_{1}, \ldots, Z_{n}$ be independent random variables, and let $X$ be another random variable. Then, the Hájek projection of $X$ with respect to $Z_{1}, \ldots, Z_{n}$ is given by

$$
\hat{X}:=\sum_{k=1}^{n} \mathbb{E}\left(X \mid Z_{k}\right)-(n-1) \mathbb{E}(X)
$$

As every $\mathbb{E}\left(X \mid Z_{k}\right)$ is a measurable function only in $Z_{k}$, the Hájek projection is a sum of independent random variables. If $\left(X_{n}\right)_{n \in \mathbb{N}}$ is a sequence of random variables with each $X_{n}$ depending on $Z_{1}, \ldots, Z_{n}$, then the Hájek projections $\hat{X}_{n}$ should give a sufficiently accurate approximation to $X_{n}$. To ensure this, the following criterion is useful.

Theorem 2.8 (cf. [11], Theorem 11.2). Consider a sequence $\left(X_{n}\right)_{n>1}$ of random variables and their associated Hájek projections $\left(\hat{X}_{n}\right)_{n \geq 1}$. If $\operatorname{Var}\left(\hat{X}_{n}\right) \sim \operatorname{Var}\left(X_{n}\right)$ as
$n \rightarrow \infty$, then

$$
\frac{X_{n}-\mathbb{E}\left(X_{n}\right)}{\operatorname{Var}\left(X_{n}\right)^{1 / 2}}=\frac{\hat{X}_{n}-\mathbb{E}\left(\hat{X}_{n}\right)}{\operatorname{Var}\left(\hat{X}_{n}\right)^{1 / 2}}+o_{\mathbb{P}}(1)
$$

## 3. Asymptotic Results

Asymptotic normality. For the univariate statistics $X_{\text {inv }}^{(d)}$ and $X_{\text {des }}^{(d)}$, the asymptotic normality has been proven in [9]. For the joint statistic $\left(X_{\text {inv }}^{(d)}, X_{\text {des }}^{(d)}\right)^{\top}$, the simplest case is when $d$ remains fixed. Then, both $X_{\text {inv }}^{(d)}$ and $X_{\text {des }}^{(d)}$ are $m$-dependent $(m=d)$ and it is not necessary to apply the Hájek approximation. From the CLT for $m$-dependent random vectors, it follows that:

Theorem 3.1. For any two fixed numbers $d_{1}, d_{2}$, the joint distribution $\left(X_{\mathrm{inv}}^{\left(d_{1}\right)}, X_{\mathrm{des}}^{\left(d_{2}\right)}\right)^{\top}$ satisfies the CLT.

An even stronger statement than the CLT is the uniform Gaussian approximation over all hyperrectangles for $m$-dependent random vectors given in [3, Theorem 2 ]. It also applies for random vectors with a sparse dependency graph. Let $\left(X_{j}^{(n)}\right)_{j=1, \ldots, n}$ be a triangular array of (w.l.o.g., centered) p-dimensional random vectors and let

$$
X^{(n)}:=\sum_{t=1}^{n} X_{t}^{(n)}, \quad \quad \Sigma^{(n)}:=\operatorname{Var}\left(X^{(n)}\right), \quad \mathcal{N} \sim \mathrm{N}_{p}\left(0, \Sigma^{(n)}\right)
$$

Let $\mathcal{A}^{\text {re }}$ be the system of all $p$-dimensional hyperrectangles, including infinite bounds, i.e., $\mathcal{A}^{\text {re }}:=\left\{\left\{\mathbf{w} \in \mathbb{R}^{p}: \mathbf{a} \leq \mathbf{w} \leq \mathbf{b}\right\} \mid \mathbf{a}, \mathbf{b} \in[-\infty, \infty]^{p}\right\}$. Let

$$
r_{n}\left(\mathcal{A}^{\mathrm{re}}\right):=\sup _{A \in \mathcal{A}^{\mathrm{re}}}\left|\mathbb{P}\left(X^{(n)} \in A\right)-\mathbb{P}(\mathcal{N} \in A)\right|
$$

In particular, $r_{n}\left(\mathcal{A}^{\text {re }}\right)$ is an upper bound for

$$
r_{n}\left(\mathcal{A}^{\mathrm{CLT}}\right):=\sup _{u \in \mathbb{R}^{p}}\left|\mathbb{P}\left(X^{(n)} \leq u\right)-\mathbb{P}\left(\mathcal{N}_{n} \leq u\right)\right|
$$

which is relevant for the CLT, and for

$$
r_{n}\left(\mathcal{A}^{\mathrm{ext}}\right):=\sup _{u \in \mathbb{R}^{p}}\left|\mathbb{P}\left(X^{(n)}>u\right)-\mathbb{P}\left(\mathcal{N}_{n}>u\right)\right|
$$

which is relevant for the asymptotics of extreme values. Now, let $G_{n}$ be a dependency graph for $X_{1}^{(n)}, \ldots, X_{n}^{(n)}$, which consists of all edges $(i, j)$ for which $X_{i}^{(n)}$ and $X_{j}^{(n)}$ are dependent. Let $\Delta_{n}$ be the maximum degree of $G_{n}$ and let $\Delta_{n}^{*}$ be the maximum degree of the 2-reachability graph of $G_{n}$. If the graphs $G_{n}$ are not too dense as $n \rightarrow \infty$, then $r_{n}\left(\mathcal{A}^{\mathrm{re}}\right)$ can be bounded as follows:

Theorem 3.2 (cf. [3], Theorem 2). Let $\left(X_{j}^{(n)}\right)_{j=1, \ldots, n}, r_{n}\left(\mathcal{A}^{\mathrm{re}}\right), \Delta_{n}, \Delta_{n}^{*}$ be as above. Under some conditions which are satisfied by bounded variables, it holds that

$$
r_{n}\left(\mathcal{A}^{\mathrm{re}}\right)=O\left(\frac{\left(\Delta_{n} \Delta_{n}^{*}\right)^{1 / 3} \log (p)^{7 / 6}}{n^{1 / 6}}\right) .
$$

In particular, if $\left(X_{j}^{(n)}\right)_{j=1, \ldots, n}$ is $m$-dependent for some global constant $m \in \mathbb{N}$, then $r_{n}\left(\mathcal{A}^{\mathrm{re}}\right)=O\left(n^{-1 / 6} \log (p)^{7 / 6}\right)$.

This theorem was stated by Chang et al. for high dimensions, but it also works with fixed $p$ by artificially repeating the components of a random vector in fixed dimension.

From now, we consider the univariate statistics $X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}$ and the joint statistic $\left(X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}\right)^{\top}$ for two sequences $d_{1}=d_{1}(n), d_{2}=d_{2}(n)$ with $d_{1}(n), d_{2}(n) \leq d_{\max }-1$ $\forall n \in \mathbb{N}$. Both $X_{\text {inv }}^{\left(d_{1}\right)}$ and $X_{\text {des }}^{\left(d_{2}\right)}$ are based on a sequence of classical Weyl groups $\left(W_{n}\right)_{n \in \mathbb{N}}$, where each $W_{n}$ is one of $S_{n}, B_{n}$, or $D_{n}$.

If $d_{2}=d_{2}(n)$ grows as $n \rightarrow \infty$, then there exists no constant $m \in \mathbb{N}$ for which all $X_{\text {des }}^{\left(d_{2}\right)}$ are $m$-dependent. However, the dependency structure of $X_{\text {des }}^{\left(d_{2}\right)}$ is still sparse. Recall that $X_{\text {inv }}^{\left(d_{1}\right)}$ and $X_{\text {des }}^{\left(d_{2}\right)}$ are constructed from i.i.d. random variables $Z_{1}, \ldots, Z_{n}$. According to (3), (5c), (5d), we can represent $X_{\text {des }}^{\left(d_{2}\right)}$ as a sum of indicator variables, each of which depends on at most three others. Therefore, the first-order and second-order maximum degrees $\Delta_{n}, \Delta_{n}^{*}$ are bounded in the way of $\Delta_{n} \leq 3$ and $\Delta_{n}^{*} \leq 9$. In conclusion, there are no issues with applying Theorem 3.2 if $d_{2}$ grows.

If $d_{1}=d_{1}(n)$ grows as well, then the maximum degrees $\Delta_{n}, \Delta_{n}^{*}$ of $\left(X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}\right)^{\top}$ are bounded in the way of $\Delta_{n} \leq 4 d_{1}$ and $\Delta_{n}^{*} \leq 8 d_{1}$. Moreover, we have to take into account that by (2), (5a), (5b), $X_{\text {inv }}^{\left(d_{1}\right)}$ is based on $\Theta\left(n d_{1}\right)$ summands, so we have to replace $n$ with $n d$ in Theorem 3.2. Therefore, Theorem 3.2 gives an $o(1)$ bound of $r_{n}\left(\mathcal{A}^{\text {re }}\right)$ if and only if $\left(d_{1}\right)^{2 / 3}=o\left(\left(n d_{1}\right)^{1 / 6}\right) \Longleftrightarrow d_{1}=o\left(n^{1 / 3}\right)$. For any faster growth rate of $d_{1}$, the dependency structure of $\left(X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}\right)^{\top}$ is too complex to apply Theorem 3.2. In that case, we have to replace $X_{\text {inv }}^{\left(d_{1}\right)}$ with the Hájek projection $\hat{X}_{\text {inv }}^{\left(d_{1}\right)}$. The growth rate of $d_{1}$ determines whether the condition in Theorem 2.8 is fulfilled or not. To classify the validity of this condition, we distinguish the short case $d \leq d_{\max } / 2$ and the long case $d>d_{\max } / 2$.

Lemma 3.3. Given the short case, we have for symmetric groups that

$$
\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)=\frac{1}{72}\left(4 d^{3}+6 d^{2}+2 d\right)
$$

and we have $\operatorname{Var}\left(\hat{X}_{\mathrm{inv}}^{(d)}\right)=d^{3} / 36+O\left(d^{2}\right)$ for the groups $B_{n}$ and $D_{n}$. So, if $d_{\max } / 2>$ $d \gg \sqrt{n}$, then $\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right) \sim \operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)$.

Lemma 3.4. Given the long case, $\operatorname{Var}\left(\hat{X}_{\mathrm{inv}}^{(d)}\right) \sim \operatorname{Var}\left(X_{\mathrm{inv}}^{(d)}\right)$ holds on symmetric groups if and only if $d \sim d_{\max }$. On the other classical Weyl groups, $\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right) \sim \operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)$ holds if and only if $d \sim d_{\max }$ or $d \sim d_{\max } / 2$.

From Theorem 3.2 and Slutsky's lemma, we can conclude:
Corollary 3.5. $\left(X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}\right)^{\top}$ satisfies the CLT if $d_{1}=o\left(n^{1 / 3}\right)$ or if $d_{1}$ satisfies the conditions of either Lemma 3.3 or Lemma 3.4.

Extreme values of the univariate statistics $X_{\text {inv }}^{(d)}$ and $X_{\text {des }}^{(d)}$. We now postulate the univariate and bivariate extreme value limit theorems (EVLTs) for $X_{\text {inv }}^{(d)}$ and $X_{\text {des }}^{(d)}$ with the help of the methods used in [6]. The proof of [6, Theorem 4.1] consists of two parts. The first part is to show the Gumbel attraction of the statistic that replaces $X_{\text {inv }}^{(d)}$ with $\hat{X}_{\text {inv }}^{(d)}$. This is done by an application of [3, Theorem 2], providing Gaussian approximation for $m$-dependent random vectors. The second part is to show that the error resulting from this replacement vanishes in probability. Recall that by use of

$$
\alpha_{n}=\frac{1}{\sqrt{2 \log n}}, \quad \beta_{n}=\frac{1}{\alpha_{n}}-\frac{1}{2} \alpha_{n}(\log \log n+\log (4 \pi))
$$

the maximum of $n$ i.i.d. variables $N_{1}, \ldots, N_{n} \sim \mathrm{~N}(0,1)$ is attracted to the Gumbel distribution, that is, $\forall x \in \mathbb{R}$ :

$$
\mathbb{P}\left(\max _{i=1, \ldots, n} N_{i} \leq \alpha_{n} x+\beta_{n}\right) \longrightarrow \exp (-\exp (-x))=: \Lambda(x) .
$$

Likewise, the two-dimensional standard normal distribution is attracted to the twodimensional Gumbel distribution with independent marginals. Taking $\boldsymbol{\alpha}_{n}:=\left(\alpha_{n}, \alpha_{n}\right)$, $\boldsymbol{\beta}_{n}:=\left(\beta_{n}, \beta_{n}\right) \in \mathbb{R}^{2}$ and writing "*" for component-wise multiplication, we get that for i.i.d. bivariate standard normal $\mathbf{N}_{1}, \ldots, \mathbf{N}_{n}$ and $\mathbf{x}=\left(x_{1}, x_{2}\right) \in \mathbb{R}^{2}$ :

$$
\mathbb{P}\left(\max _{i=1, \ldots, n} \mathbf{N}_{i} \leq \boldsymbol{\alpha}_{n} * \mathbf{x}+\boldsymbol{\beta}_{n}\right) \longrightarrow \exp \left(-\exp \left(-x_{1}\right)-\exp \left(-x_{2}\right)\right)=: \Lambda_{2}(x)
$$

Since the random numbers of generalized inversions and descents are discrete distributions, we are interested in the extremes of a triangular array $\left(X_{n 1}, \ldots, X_{n k_{n}}\right)$, where for each $n \in \mathbb{N}$, the block $X_{n 1}, \ldots, X_{n k_{n}}$ consists of i.i.d. samples taken from the $n$-th symmetric group $S_{n}$. Each of the following EVLTs imposes an upper bound on the number of samples $k_{n}$.
For a univariate triangular array consisting of generalized descents, it is not necessary to use the Hájek projection. It has already been argued in [6, Remark 4.2] that a subexponential bound of $k_{n}$ can be obtained if the Hájek projection is not needed. So, in the univariate EVLT for generalized descents, we can use the bound of $k_{n}=\exp \left(o\left(n^{1 / 7}\right)\right)$ stated in [6, Remark 4.2]:

Theorem 3.6. Let $\left(X_{n j}\right)_{j=1, \ldots, k_{n}}$ be a row-wise i.i.d. triangular array with $X_{n 1} \stackrel{\mathcal{D}}{=} X_{\text {des }}^{(d)}$ for any sequence $d=d(n)$ with $1 \leq d \leq d_{\max }-1$, and let $M_{n}:=\max \left\{X_{n 1}, \ldots, X_{n k_{n}}\right\}$. Let $a_{n}:=\sigma\left(X_{\text {des }}^{(d)}\right) \alpha_{k_{n}}$ and let $b_{n}:=\sigma\left(X_{\text {des }}^{(d)}\right) \beta_{k_{n}}+\mu\left(X_{\text {inv }}^{(d)}\right)$. If $k_{n}=\exp \left(o\left(n^{1 / 7}\right)\right)$, then

$$
\forall x \in \mathbb{R}: \quad \mathbb{P}\left(M_{n} \leq a_{n} x+b_{n}\right) \longrightarrow \Lambda(x)
$$

A similar statement applies to $X_{\text {inv }}^{(d)}$ if $d$ grows slow enough to permit the application of Theorem 3.2.

Theorem 3.7. Let $\left(X_{n 1}, \ldots, X_{n k_{n}}\right)$ be a row-wise i.i.d. triangular array with $X_{n 1} \stackrel{\mathcal{D}}{=}$ $X_{\mathrm{inv}}^{(d)}$, where $d=d(n)=o\left(n^{1 / 3}\right)$. Let $M_{n}, a_{n}, b_{n}$ be given in analogy to Theorem 3.6. If $k_{n}=\exp \left(o\left(n^{1 / 7} / d^{3 / 7}\right)\right)$, then

$$
\forall x \in \mathbb{R}: \quad \mathbb{P}\left(M_{n} \leq a_{n} x+b_{n}\right) \longrightarrow \Lambda(x)
$$

Proof. According to the above considerations, the maximum degrees $\Delta_{n}, \Delta_{n}^{*}$ in the dependency graph of the representations (2), (5a), and (5b) are bounded in the way of $\Delta_{n} \leq 4 d$ and $\Delta_{n}^{*} \leq 8 d$. Since these representations are based on $\Theta(n d)$ summands, we need to replace $n$ with $n d$ when applying Theorem 3.2. An application of Theorem 3.2 with $\max \left\{n, k_{n}\right\}$ i.i.d. iterations of $X_{\text {inv }}^{(d)}$ yields

$$
\left|\mathbb{P}\left(M_{n} \leq a_{n} x+b_{n}\right)-\mathbb{P}\left(\mathcal{M}_{n} \leq \alpha_{n} x+\beta_{n}\right)\right|=O\left(n^{-1 / 6} d^{1 / 2}\right) \log \left(k_{n}\right)^{7 / 6}=o(1)
$$

where $\mathcal{M}_{n}$ is the maximum of $n$ i.i.d. copies of the standard normal distribution. The claim follows.

For any other growth rate of $d$, we can state an EVLT only for the cases covered by Lemmas 3.3 and 3.4, and due to the use of Hájek's projection, we can only impose a strongly reduced asymptotic bound for $k_{n}$.

Theorem 3.8. Let $\left(X_{n 1}, \ldots, X_{n k_{n}}\right)$ be a row-wise i.i.d. triangular array with $X_{n 1} \stackrel{\mathcal{D}}{=}$ $X_{\mathrm{inv}}^{(d)}$, where $d=d(n)$ satisfies the conditions in either Lemma 3.3 or 3.4. Assume $k_{n} \log \left(k_{n}\right)=o\left(n^{-1} d^{2}\right)$ in the short case and $k_{n} \log \left(k_{n}\right)=o\left(\min \left\{n, \frac{n}{n-d}\right\}\right)$ in the long case. Let $M_{n}:=\max \left\{X_{n 1}, \ldots, X_{n k_{n}}\right\}$ be the row-wise maximum. Then,

$$
\forall x \in \mathbb{R}: \quad \mathbb{P}\left(M_{n} \leq a_{n} x+b_{n}\right) \longrightarrow \Lambda(x),
$$

with $a_{n}, b_{n}$ given in analogy to Theorem 3.6.
Proof. The conditions on $d$ ensure that $1-\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right) / \operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)=o(1)$, but the rate of convergence determines the bound for $k_{n}$ by means of [ 6 , Eq. (9), (10)]. We compute this rate for symmetric groups, since the same conclusions can be obtained on the other classical Weyl groups. In the short case, we have

$$
1-\frac{\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)}{\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)}=1-\frac{4 d^{3}+6 n d+3 d^{2}-d}{4 d^{3}+6 d^{2}+2 d}=\frac{4 d^{2}+6 n+3 d-1}{4 d^{2}+6 d+2}
$$

$$
\begin{aligned}
& =1-\frac{4 d^{2}}{4 d^{2}+6 d+2}-\frac{3 d+1}{4 d^{2}+6 d+2}-\frac{6 n}{4 d^{2}+6 d+2} \\
& =\Theta\left(\frac{1}{d}\right)-\frac{6 n}{4 d^{2}+6 d+2}
\end{aligned}
$$

Apparently, $6 n /\left(4 d^{2}+6 d+2\right)$ always dominates $1 / d$. In conclusion,

$$
1-\frac{\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)}{\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)}=\Theta\left(\frac{n}{d^{2}}\right)
$$

giving the condition of $k_{n} \log \left(k_{n}\right)=o\left(d^{2} / n\right)$ according to the arguments in the proof of [6, Theorem 4.1]. The remaining steps of the proof are the same.

In the long case, we write $\delta:=n-d$ and note that

$$
\begin{aligned}
& \operatorname{Var}\left(\hat{X}_{\text {inv }}\right)=-\frac{1}{6}(n-\delta)^{3}+\frac{1}{3}(n-\delta)^{2} n-\frac{5}{36} n^{3}+\frac{16}{36} n^{2} \delta+O\left(n^{2}\right), \\
& \operatorname{Var}\left(X_{\text {inv }}\right)=-\frac{1}{6}(n-\delta)^{3}+\frac{1}{3}(n-\delta)^{2} n-\frac{5}{36} n^{3}+\frac{6}{36} n^{2} \delta+O\left(n^{2}\right) .
\end{aligned}
$$

Therefore,

$$
1-\frac{\operatorname{Var}\left(X_{\text {inv }}\right)}{\operatorname{Var}\left(\hat{X}_{\text {inv }}\right)}=\frac{10 n^{2} \delta+O\left(n^{2}\right)}{\Theta\left(n^{3}\right)}=\Theta\left(\max \left\{\frac{\delta}{n}, \frac{1}{n}\right\}\right),
$$

giving the requirement of

$$
k_{n} \log \left(k_{n}\right) \Theta\left(\max \left\{\frac{\delta}{n}, \frac{1}{n}\right\}\right)=o(1) \Longleftrightarrow k_{n} \log \left(k_{n}\right)=o\left(\min \left\{n, \frac{n}{\delta}\right\}\right) .
$$

Again, the proof now follows the same steps as in [6, Theorem 4.1].
Remark 3.9. This result is only useful if $d \gg n^{3 / 4}$. Otherwise, we can obtain the EVLT with a bound of $k_{n}=o\left(n^{1 / 2}\right)$ from the universal EVLT [7, Theorem 5.1].

Extreme values of the joint distribution of $X_{\mathrm{inv}}^{(d)}$ and $X_{\text {des }}^{(d)}$. The bivariate EVLT for $\left(X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}\right)^{\top}$ follows the same way, since the descent component does not interfere with any of the previously used arguments.
Theorem 3.10. Let $\left(X_{n 1}, \ldots, X_{n k_{n}}\right)$ be a row-wise i.i.d. triangular array with $X_{n 1} \stackrel{\mathcal{D}}{\underline{1}}$ $\left(X_{\text {inv }}^{\left(d_{1}\right)}, X_{\text {des }}^{\left(d_{2}\right)}\right)^{\top}$ on $S_{n}$.
(a) If $d_{1}=o\left(n^{1 / 3}\right)$, then assume $k_{n}=\exp \left(o\left(n^{1 / 7} / d^{3 / 7}\right)\right)$.
(b) If $d_{1}$ satisfies the conditions in either Lemma 3.3 or 3.4 , then assume $k_{n} \log \left(k_{n}\right)=$ $o\left(n^{-1} d_{1}^{2}\right)$ in the short case and $k_{n} \log \left(k_{n}\right)=o\left(\min \left\{n, \frac{n}{n-d_{1}}\right\}\right)$ in the long case.

Let $M_{n}:=\max \left\{X_{n 1}, \ldots, X_{n k_{n}}\right\}$ be the row-wise maximum. Let $\mu_{n}:=\mathbb{E}\left(X_{n 1}\right)$ and let $s_{n}:=\left(\sigma\left(X_{\text {inv }}^{(d)}\right), \sigma\left(X_{\text {des }}\right)\right)$. Let $a_{n}:=s_{n} * \boldsymbol{\alpha}_{k_{n}}$ and let $b_{n}:=s_{n} * \boldsymbol{\beta}_{k_{n}}+\mu_{n}$. Then,

$$
\forall \mathbf{x} \in \mathbb{R}^{2}: \quad \mathbb{P}\left(M_{n} \leq a_{n} * \mathbf{x}+b_{n}\right) \longrightarrow \Lambda_{2}(\mathbf{x})
$$

## 4. Proofs of Lemmas 3.3 and 3.4

We first consider $\hat{X}_{\text {inv }}^{(d)}$ on symmetric groups and then provide the analogous observations on the other classical Weyl groups.

Proof of Lemma 3.3 for symmetric groups. By (2), we have

$$
\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)=\sum_{(i, j) \in \mathfrak{N}_{n, d}} \mathbb{P}\left(Z_{i}>Z_{j} \mid Z_{k}\right)=\sum_{(i, j) \in \mathfrak{N}_{n, d}} \begin{cases}1 / 2, & k \notin\{i, j\} \\ Z_{k}, & k=i \\ 1-Z_{k}, & k=j\end{cases}
$$

Only the pairs $(i, j)$ with $k \in\{i, j\}$ contribute to $\operatorname{Var}\left(\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)\right)$. These contributions are called the non-trivial parts for simplicity. The number of these pairs depends on whether $k$ belongs to $K_{1}, K_{2}$, or $K_{3}$, as already seen in Remark 2.2. Figure 1 visualizes this case distinction for the exemplary choice of $n=15$ and $d=4$.
If $k \in K_{2}$, then the non-trivial parts are

$$
\underbrace{Z_{k}+Z_{k}+\ldots+Z_{k}}_{d \text { times }}+\underbrace{\left(1-Z_{k}\right)+\left(1-Z_{k}\right)+\ldots+\left(1-Z_{k}\right)}_{d \text { times }}=d .
$$

This means $\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)$ is constant due to cancellation, and vanishes when computing the variance. So, in the short case, $\operatorname{Var}\left(\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)\right)$ originates only from $K_{1}$ and $K_{3}$. If $k \in K_{1}$, then $\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)=(k-1)\left(1-Z_{k}\right)+d Z_{k}+$ const $=(d+1-k) Z_{k}+$ const. If $k \in K_{3}$, then $\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)=(n-k) Z_{k}+d\left(1-Z_{k}\right)+$ const $=(n-d-k) Z_{k}+$ const. So, the overall representation of $\hat{X}_{\text {inv }}^{(d)}$ in the short case is

$$
\hat{X}_{\mathrm{inv}}^{(d)}=\sum_{k=1}^{n} \omega_{d}(k) Z_{k}+\mathrm{const}, \quad \text { with } \quad \omega_{d}(k):= \begin{cases}d-k+1, & k \in K_{1} \\ 0, & k \in K_{2} \\ n-d-k, & k \in K_{3}\end{cases}
$$

Therefore,

$$
\begin{aligned}
\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right) & =\operatorname{Var}\left(\sum_{k=n-d+1}^{n}(n-k-d) Z_{k}+\sum_{k=1}^{d}(d+1-k) Z_{k}\right) \\
& =\sum_{k=n-d+1}^{n} \frac{1}{12}(n-k-d)^{2}+\sum_{k=1}^{d} \frac{1}{12}(d+1-k)^{2}
\end{aligned}
$$

Figure 1. Overview of relevant pairs $(i, j)$ for computing the variance of $\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)$, where $n=15$ and $d=4$. For each of the regions $K_{1}, K_{2}, K_{3}$, an exemplary index $k$ is chosen, and the pairs that give a non-trivial contribution are highlighted in red for $k \in K_{1}$, in blue for $k \in K_{2}$, and in green for $k \in K_{3}$.

$$
\begin{aligned}
& =\frac{1}{12} \sum_{k=1}^{d} k^{2}+\frac{1}{12} \sum_{k=1}^{d}(-k)^{2}=\frac{1}{6} \frac{d(d+1)(2 d+1)}{6} \\
& =\frac{1}{72}\left(4 d^{3}+6 d^{2}+2 d\right)
\end{aligned}
$$

So, the leading term is always $4 d^{3} / 72$. In light of Theorem 2.3 , according to which $\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)$ contains the monomials $6 n d / 72$ and $4 d^{3} / 72$, it must be ensured that $d^{3}$ is dominant over $n d$. This means $d \gg \sqrt{n}$.

Now, we consider the long case. Due to $d>n / 2$, we now have $n-d<d$, and the regions $K_{1}, K_{2}, K_{3}$ are redefined according to Remark 2.2. For the non-trivial parts, we note that:

- If $k \in K_{1}$ or $k \in K_{3}$, then the non-trivial parts are the same as in the short case.
- If $k \in K_{2}$, then the non-trivial parts yield $\mathbb{E}\left(X_{\text {inv }}^{(d)} \mid Z_{k}\right)=(n-2 k+1) Z_{k}+$ const. So, we again obtain a representation in the way of

$$
\hat{X}_{\text {inv }}^{(d)}=\sum_{k=1}^{n} \omega_{d}(k) Z_{k}+\text { const }, \quad \text { with } \quad \omega_{d}(k):= \begin{cases}d-k+1, & k \in K_{1}  \tag{6}\\ n-2 k+1, & k \in K_{2} \\ n-d-k, & k \in K_{3}\end{cases}
$$

The proof of the following lemma shows that if $d \nsim n$, then the leading terms of $\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)$ and $\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)$ do not match perfectly.
Proof of Lemma 3.4 for symmetric groups. From (6), we state that

$$
\begin{align*}
\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right) & =\frac{1}{12} \sum_{k=1}^{n-d}(d+1-k)^{2}  \tag{6a}\\
& +\frac{1}{12} \sum_{k=n-d+1}^{d}(n-2 k+1)^{2}  \tag{6b}\\
& +\frac{1}{12} \sum_{k=d+1}^{n}(n-k-d)^{2} \tag{6c}
\end{align*}
$$

By appropriate index shifting, we calculate

$$
\begin{aligned}
(6 \mathrm{a}),(6 \mathrm{c}) & =\frac{1}{12}\left(\sum_{k=1}^{d} k^{2}-\sum_{k=1}^{2 d-n} k^{2}\right) \\
\Longrightarrow(6 \mathrm{a})+(6 \mathrm{c}) & =\frac{1}{6}\left(\sum_{k=1}^{d} k^{2}-\sum_{k=1}^{2 d-n} k^{2}\right) \\
& =\frac{1}{36}(n-d)\left(14 d^{2}+d(9-10 n)+12 n^{2}-3 n+1\right), \\
(6 \mathrm{~b}) & =\frac{1}{36}(2 d-n)\left(4 d^{2}-4 d n+n^{2}-1\right) .
\end{aligned}
$$

This gives the total result

$$
\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)=\frac{1}{36}\left(-6 d^{3}+12 d^{2} n-9 d^{2}-16 d n^{2}+12 d n-3 d+11 n^{3}-3 n^{2}+2 n\right) .
$$

In contrast, by Theorem 2.3,

$$
\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)=\frac{1}{36}\left(-6 d^{3}+\left(12 n-\frac{21}{2}\right) d^{2}-\left(6 n^{2}-15 n+\frac{9}{2}\right) d+n^{3}-3 n^{2}+2 n\right) .
$$

Since the long case implies $n / 2<d<n$, all monomials of order 3 are leading terms. The monomials $-16 d n^{2}+11 n^{3}$ appearing in $\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)$ and $-6 n^{2} d+n^{3}$ appearing in
$\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)$ do not match in general. Using $\delta:=n-d$, we can write

$$
\begin{aligned}
\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right) & =-\frac{1}{6}(n-\delta)^{3}+\frac{1}{3}(n-\delta)^{2} n-\frac{5}{36} n^{3}+\frac{16}{36} n^{2} \delta+O\left(n^{2}\right), \\
\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right) & =-\frac{1}{6}(n-\delta)^{3}+\frac{1}{3}(n-\delta)^{2} n-\frac{5}{36} n^{3}+\frac{6}{36} n^{2} \delta+O\left(n^{2}\right)
\end{aligned}
$$

This shows that we need $\delta=o(n)$, since otherwise, there are two different leading coefficients of $n^{3}$.

We now derive the analogous statements for the other classical Weyl groups $B_{n}$ and $D_{n}$. It is sufficient to prove the lemmas 3.3 and 3.4 for the groups $B_{n}$, since the difference between $X_{\text {inv }}^{B,(d)}$ and $X_{\text {inv }}^{D,(d)}$ is asymptotically negligible (cf. (5a) and (5b)). Recall the asymptotic quantification of $\operatorname{Var}\left(X_{\text {inv }}^{(d)}\right)$ given in Lemma 2.6.

To compute $\operatorname{Var}\left(\hat{X}_{\text {inv }}^{(d)}\right)$, we ignore all constant parts appearing in $\hat{X}_{\text {inv }}^{(d)}$. By (5a), we can split $\mathbb{E}\left(X_{\text {inv }}^{B,(d)} \mid Z_{k}\right)=\mathbb{E}\left(X_{\text {inv }}^{B,(d)} \mid Z_{k}\right)^{+}+\mathbb{E}\left(X_{\text {inv }}^{B,(d)} \mid Z_{k}\right)^{-}+\mathbb{E}\left(X_{\text {inv }}^{B,(d)} \mid Z_{k}\right)^{\circ}$, where

$$
\begin{aligned}
& \mathbb{E}\left(X_{\mathrm{inv}}^{B,(d)} \mid Z_{k}\right)^{+}:=\sum_{(i, j) \in \mathfrak{N}_{n, d}} \mathbb{P}\left(Z_{i}>Z_{j} \mid Z_{k}\right), \\
& \mathbb{E}\left(X_{\mathrm{inv}}^{B,(d)} \mid Z_{k}\right)^{-}:=\sum_{(i, j) \in \widetilde{\mathscr{N}}_{n, d}} \mathbb{P}\left(-Z_{i}>Z_{j} \mid Z_{k}\right), \\
& \mathbb{E}\left(X_{\mathrm{inv}}^{B,(d)} \mid Z_{k}\right)^{\circ}:=\sum_{i=1}^{n} \mathbb{P}\left(Z_{i}<0 \mid Z_{k}\right) .
\end{aligned}
$$

The third sum $\mathbb{E}\left(X_{\text {inv }}^{B,(d)} \mid Z_{k}\right)^{\circ}$ is asymptotically negligible. So, to obtain a representation $\hat{X}_{\text {inv }}^{B,(d)}=\sum_{i=1}^{n} \omega_{d}(k) Z_{k}+$ const, we write $\omega_{d}(k)=\omega_{d}(k)^{+}+\omega_{d}(k)^{-}$, with $\omega_{d}(k)^{+}$ stemming from $\mathbb{E}\left(X_{\text {inv }}^{B,(d)} \mid Z_{k}\right)^{+}$and $\omega_{d}(k)^{-}$stemming from $\mathbb{E}\left(X_{\text {inv }}^{B,(d)} \mid Z_{k}\right)^{-}$, respectively.

For $\omega_{d}(k)^{+}$, we can use the previous counting method. However, we have to take into account that on $B_{n}$,

$$
\begin{array}{rlrl}
\mathbb{P}\left(Z_{k}>Z_{j} \mid Z_{k}\right) & =\frac{Z_{k}+1}{2}, & \mathbb{P}\left(Z_{i}>Z_{k} \mid Z_{k}\right)=\frac{1-Z_{k}}{2} \\
\mathbb{P}\left(-Z_{k}>Z_{j} \mid Z_{k}\right)=\frac{1-Z_{k}}{2}, & \mathbb{P}\left(Z_{i}>Z_{k} \mid Z_{k}\right)=\frac{1-Z_{k}}{2}
\end{array}
$$

In conclusion, the coefficients $\omega_{d}(k)^{+}$on $B_{n}$ are half of the coefficients $\omega_{d}(k)$ on $S_{n}$. Note that $\omega_{d}(k)^{+}=(n-2 k+1) / 2$ for all $d \geq n$. Moreover, $\omega_{d}(k)^{-}=-\widetilde{N}_{n, d}^{(k)} / 2$, where

$$
\widetilde{N}_{n, d}^{(k)}:=\mid\left\{(i, j) \in \widetilde{\mathfrak{N}}_{n, d} \mid \text { either } i=k \text { or } j=k\right\} \mid .
$$

Recall that by Remark 2.5, the short case is now $d<n$ and the long case is $d \geq n$. By counting the number of such $(k, j)$ and $(i, k)$, we can determine the asymptotic quantification of $\operatorname{Var}\left(\hat{X}_{\text {inv }}^{B,(d)}\right)$.

Proof of Lemma 3.3 for the groups $B_{n}$ and $D_{n}$. If $d \leq n / 2$, then all pairs in $\tilde{\mathfrak{N}}_{n, d}$ are located within $K_{1}$, yielding

$$
\begin{aligned}
\omega_{d}(k) & = \begin{cases}(d-k+1) / 2-(d-k-1) / 2, & k \leq d / 2 \\
(d-k+1) / 2-(d-k) / 2, & d / 2<k \leq d \\
0, & d<k \leq n-d \\
(n-d-k) / 2, & n-d<k \leq n\end{cases} \\
& = \begin{cases}(n-d-k) / 2, & n-d<k \leq n \\
O(1), & \text { otherwise } .\end{cases}
\end{aligned}
$$

In conclusion, if $d \leq n / 2$, then

$$
\begin{aligned}
\operatorname{Var}\left(\hat{X}_{\text {inv }}^{B,(d)}\right) & =\frac{1}{3} \sum_{k=1}^{n} \omega_{d}(k)^{2}+O\left(d^{2}\right)=\frac{1}{12} \sum_{k=n-d+1}^{n}(n-d-k)^{2}+O\left(d^{2}\right) \\
& =\frac{1}{12} \frac{d(d+1)(2 d+1)}{6}+O\left(d^{2}\right)=\frac{1}{36} d^{3}+O\left(d^{2}\right)
\end{aligned}
$$

Due to $\operatorname{Var}\left(X_{\text {inv }}^{B,(d)}\right)=d^{3} / 36+n d / 12+O\left(d^{2}\right)$ according to Lemma 2.6, we obtain the same condition as in Lemma 3.3, namely, $d \gg \sqrt{n}$.

If $n / 2<d<n$, then the pairs in $\widetilde{\mathfrak{N}}_{n, d}$ also cover $K_{2}$. For $k \in K_{2}$, there cannot be any pairs $(k, j)$ if $n / 2<d \leq 2 n / 3$, while this is possible if $d>2 n / 3$. However, the difference between these two subcases is only marginal. If $n / 2<d \leq 2 n / 3$, we obtain

$$
\omega_{d}(k)= \begin{cases}O(1), & k \in K_{1} \\ (n-2 k+1-(d-k)) / 2, & k \in K_{2} \\ (n-d-k) / 2, & k \in K_{3}\end{cases}
$$

If $d>2 n / 3$, then

$$
\omega_{d}(k)=\left\{\begin{array}{ll}
O(1), & k \in K_{1} \\
(n-2 k+1-(d-k-1)) / 2, & k \in K_{2}, k \leq d / 2 \\
(n-2 k+1-(d-k)) / 2, & k \in K_{2}, k>d / 2 \\
(n-d-k) / 2, & k \in K_{3}
\end{array} .\right.
$$

In conclusion, if $n / 2<d<n$, then

$$
\begin{aligned}
\operatorname{Var}\left(\hat{X}_{\mathrm{inv}}^{B,(d)}\right) & =\frac{1}{3} \sum_{k=1}^{n} \omega_{d}(k)^{2}+O\left(d^{2}\right) \\
& =\frac{1}{12} \sum_{k=n-d+1}^{d}(n-d-k+1)^{2}+\frac{1}{12} \sum_{k=d+1}^{n}(n-d-k)^{2}+O\left(d^{2}\right)
\end{aligned}
$$

$$
\begin{aligned}
& =\frac{1}{12} \sum_{k=n-d+1}^{d}(n-d-k+1)^{2}+\frac{1}{12} \sum_{k=1}^{2 d-n} k^{2}+O\left(d^{2}\right) \\
& =\frac{1}{12} \sum_{k=1}^{2 d-n-1} k^{2}+\frac{1}{12}\left(\sum_{k=1}^{d} k^{2}-\sum_{k=1}^{2 d-n} k^{2}\right)+O\left(d^{2}\right) \\
& =\frac{1}{36} d^{3}+O\left(d^{2}\right)
\end{aligned}
$$

Proof of Lemma 3.4 for the groups $B_{n}$ and $D_{n}$. In the long case, the main focus is on counting $\widetilde{N}_{n, d}^{(k)}$. Figure 2 illustrates the positions of pairs $(i, j) \in \widetilde{\mathfrak{N}}_{n, d}$ in the long case for the exemplary choice of $n=12, d=16$.

Figure 2. Visualization of pairs $(i, j)$ in $\widetilde{\mathfrak{N}}_{n, d}$ in the long case for $n=12$ and $d=16$. The numbers $d-n$ and $d / 2$ are important case distinction thresholds for counting the pairs $(k, j)$ and $(i, k)$, respectively.

With help of Figure 2, it is straightforward to count

$$
\widetilde{N}_{n, d}^{(k)}=\left\{\begin{array}{ll}
n-1, & 1 \leq k \leq d-n \\
d-k-1, & d-n<k \leq d / 2 \\
d-k, & d / 2<k \leq n
\end{array} .\right.
$$

This result is also illustrated in Figure 3, which displays the number of pairs $(i, k)$ and the number of pairs $(k, j)$.

Figure 3. Plots of the numbers of pairs $(i, k)$ (red) and $(k, j)$ (blue) in $\widetilde{\mathfrak{N}}_{n, d}$. The sum of these two numbers is $\widetilde{N}_{n, d}^{(k)}$, which is displayed by the black crossed points.

Therefore, in the long case, we have

$$
\omega_{d}(k)= \begin{cases}1-k, & 1 \leq k \leq d-n \\ (n+2-d-k) / 2, & d-n<k \leq d / 2 \\ (n+1-d-k) / 2, & d / 2<k \leq n\end{cases}
$$

We compute

$$
\begin{aligned}
\sum_{k=1}^{n} \omega_{d}(k)^{2} & =\sum_{k=1}^{d-n}(k-1)^{2}+\frac{1}{4} \sum_{k=d-n+1}^{n}(n-d+1-k)^{2}+O\left(n^{2}\right) \\
& =\sum_{k=1}^{d-n-1} k^{2}+\frac{1}{4} \sum_{k=d-n+1}^{n}(k-(d-n-1))^{2}+O\left(n^{2}\right)
\end{aligned}
$$

$$
\begin{aligned}
& =\frac{1}{3}(d-n-1)^{3}+\frac{1}{12}(2 n-d-1)^{3}+O\left(n^{2}\right) \\
& =\frac{d^{3}}{4}-\frac{d^{2} n}{2}-\frac{3 d^{2}}{4}+d n+\frac{3 d}{4}+\frac{n^{3}}{3}-\frac{n}{2}+\frac{1}{4}+O\left(n^{2}\right) .
\end{aligned}
$$

Due to $\operatorname{Var}\left(Z_{k}\right)=1 / 3$, we obtain

$$
\operatorname{Var}\left(\hat{X}_{\mathrm{inv}}^{B,(d)}\right)=\frac{d^{3}}{12}-\frac{d^{2} n}{6}+\frac{n^{3}}{9}+O\left(d^{2}\right) .
$$

On the other hand, by Lemma 2.6,

$$
\operatorname{Var}\left(X_{\mathrm{inv}}^{B,(d)}\right)=-\frac{1}{12} d^{3}+\frac{1}{3} n d^{2}-\frac{1}{3} n^{2} d+\frac{1}{9} n^{3}+O\left(d^{2}\right),
$$

i.e., the leading terms $d^{3} / 12-d^{2} n / 6$ and $-d^{3} / 12+n d^{2} / 3-n^{2} d / 3$ need to match. Writing $d=c n(1+o(1))$ for $1 \leq c \leq 2$, this gives the condition

$$
\frac{(c n)^{3}}{12}-\frac{c^{2} n^{3}}{6}=-\frac{(c n)^{3}}{12}+\frac{c^{2} n^{3}}{3}-\frac{c n^{3}}{3} \Longleftrightarrow \frac{c^{3}}{6}-\frac{c^{2}}{2}+\frac{c}{3}=0,
$$

which holds precisely for $c=1$ and $c=2$.
