# A $q$-ANALOG OF THE STIRLING-EULERIAN POLYNOMIALS 

YAO DONG, ZHICONG LIN, AND QIONGQIONG PAN

#### Abstract

In 1974, Carlitz and Scoville introduced the Stirling-Eulerian polynomial $A_{n}(x, y \mid \alpha, \beta)$ as the enumerator of permutations by descents, ascents, left-to-right maxima and right-to-left maxima. Recently, Ji considered a refinement of $A_{n}(x, y \mid \alpha, \beta)$, denoted $P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right)$, which is the enumerator of permutations by valleys, peaks, double ascents, double descents, left-to-right maxima and right-to-left maxima. Using Chen's context-free grammar calculus, Ji proved a formula for the generating function of $P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right)$, generalizing the work of Carlitz and Scoville. Ji's formula has many nice consequences, one of which is an intriguing $\gamma$-positivity expansion for $A_{n}(x, y \mid \alpha, \beta)$. In this paper, we prove a $q$-analog of Ji's formula by using Gessel's $q$-compositional formula and provide a combinatorial approach to her $\gamma$-positivity expansion of $A_{n}(x, y \mid \alpha, \beta)$.

## 1. Introduction

Using Chen's context-free grammar [5], Ji [10] recently proved a formula for the generating function of permutations by valleys, peaks, double ascents, double descents, left-to-right maxima and right-to-left maxima. The main objective of this paper is to prove a $q$-analog of Ji's formula by using Gessel's $q$-compositional formula [9]. We need some further notations and definitions before we can state our $q$-analog of Ji's formula.

Let $\mathfrak{S}_{n}$ be the set of permutations of $[n]:=\{1, \ldots, n\}$. An index $i \in[n-1]$ is a descent (resp., ascent) of $\sigma=\sigma_{1} \cdots \sigma_{n} \in \mathfrak{S}_{n}$ if $\sigma_{i}>\sigma_{i+1}$ (resp., $\sigma_{i}<\sigma_{i+1}$ ). The Eulerian polynomials $A_{n}(x)$ can be described as the enumerator of $\mathfrak{S}_{n}$ by descents or ascents, that is

$$
\begin{equation*}
A_{n}(x):=\sum_{\sigma \in \mathfrak{S}_{n}} x^{\operatorname{des}(\sigma)}=\sum_{\sigma \in \mathfrak{S}_{n}} x^{\operatorname{asc}(\sigma)}, \tag{1.1}
\end{equation*}
$$

where $\operatorname{des}(\sigma)$ (resp., $\operatorname{asc}(\sigma)$ ) denotes the number of descents (resp., ascents) of $\sigma$. There is a well-known formula (see [14, p. 13]) for the exponential generating function for $A_{n}(x)$ :

$$
\begin{equation*}
1+\sum_{n \geq 1} x A_{n}(x) \frac{t^{n}}{n!}=\frac{1-x}{1-x e^{(1-x) t}} . \tag{1.2}
\end{equation*}
$$

A permutation statistic whose generating function equals (1.1) is called Eulerian. Another classical Eulerian statistic (see [17, p. 23]) is the number of excedances "exc", where

$$
\operatorname{exc}(\sigma):=\#\left\{i \in[n-1]: \sigma_{i}>i\right\} .
$$

Another class of fundamental permutation statistics is the so-called Stirling statistics. A left-to-right maximum (resp., left-to-right minimum) of $\sigma \in \mathfrak{S}_{n}$ is an element $\sigma_{i}$ such that

[^0]$\sigma_{j}<\sigma_{i}$ (resp., $\sigma_{j}>\sigma_{i}$ ) for every $j<i$. Let $\operatorname{lma}(\sigma)$ and $\operatorname{lmi}(\sigma)$ denote the numbers of left-to-right maxima and left-to-right minima of $\sigma$, respectively. Similarly, we can define the right-to-left maximum (resp., right-to-left minimum) of $\sigma$ and denote rma $(\sigma)$ (resp., $\operatorname{rmi}(\sigma)$ ) the number of right-to-left maxima (resp., right-to-left minima) of $\sigma$. It is well known (see [17, p. 20]) that the unsigned Stirling numbers of the first kind count permutations by their number of left-to-right maxima, namely
$$
(x)_{n}:=x(x+1)(x+2) \cdots(x+n-1)=\sum_{\sigma \in \mathfrak{G}_{n}} x^{\operatorname{lma}(\sigma)}
$$

Therefore, each statistic whose distribution over $\mathfrak{S}_{n}$ gives $(x)_{n}$ is called Stirling. So "lmi", "rma" and "rmi" are all Stirling statistics by the symmetry of permutations and according to Foata's first fundamental transformation (see [17, Prop. 1.3.1]), the statistic "cyc" is also Stirling, where $\operatorname{cyc}(\sigma)$ denotes the number of cycles of $\sigma$.

Carlitz and Scoville [4] considered the following polynomials involving Stirling-Eulerian Statistics, which we refer to as the Stirling-Eulerian polynomials ${ }^{1}$ :

$$
\begin{aligned}
A_{n}(x, y \mid \alpha, \beta) & =\sum_{\sigma \in \mathfrak{S}_{n}} x^{\operatorname{asc}(\sigma)} y^{\operatorname{des}(\sigma)} \alpha^{\operatorname{lma}(\sigma)-1} \beta^{\operatorname{rma}(\sigma)-1} \\
& =\sum_{\sigma \in \mathfrak{S}_{n}} x^{\operatorname{des}(\sigma)} y^{\operatorname{asc}(\sigma)} \alpha^{\operatorname{lmi}(\sigma)-1} \beta^{\operatorname{rin}(\sigma)-1} .
\end{aligned}
$$

Here the second interpretation follows from the complement

$$
\sigma=\sigma_{1} \sigma_{2} \cdots \sigma_{n} \mapsto \sigma^{c}=\left(n+1-\sigma_{1}\right)\left(n+1-\sigma_{2}\right) \cdots\left(n+1-\sigma_{n}\right)
$$

of permutations. In [4, Theorem 9], they obtained the following generating function formula for $A_{n}(x, y \mid \alpha, \beta)$ :

$$
\begin{equation*}
\sum_{n \geq 0} A_{n+1}(x, y \mid \alpha, \beta) \frac{t^{n}}{n!}=(1+x F(x, y ; t))^{\alpha}(1+y F(x, y ; t))^{\beta} \tag{1.3}
\end{equation*}
$$

where

$$
\begin{equation*}
F(x, y ; t):=\frac{e^{x t}-e^{y t}}{x e^{y t}-y e^{x t}} \tag{1.4}
\end{equation*}
$$

Recently, Ji [10] refined the Carlitz-Scoville formula (1.3) by using the following refinements of descents and ascents.

Definition 1. For a permutation $\sigma \in \mathfrak{S}_{n}$ with some specified boundary condition (i.e., specified values of $\sigma_{0}$ and $\left.\sigma_{n+1}\right)$, the index $i \in[n]$ is

- a peak if $\sigma_{i-1}<\sigma_{i}>\sigma_{i+1}$;
- a valley if $\sigma_{i-1}>\sigma_{i}<\sigma_{i+1}$;
- a double ascent if $\sigma_{i-1}<\sigma_{i}<\sigma_{i+1}$;
- a double descent if $\sigma_{i-1}>\sigma_{i}>\sigma_{i+1}$.

[^1]Let $\mathrm{M}(\sigma), \mathrm{V}(\sigma)$, da $(\sigma)$ and $\operatorname{dd}(\sigma)$ (resp., $\widetilde{\mathrm{M}}(\sigma), \widetilde{\mathrm{V}}(\sigma)$, $\mathrm{da}(\sigma)$ and $\tilde{\mathrm{d} d}(\sigma)$ ) denote respectively the number of peaks, valleys, double ascents and double descents in $\sigma$ with boundary condition $\sigma_{0}=\sigma_{n+1}=0$ (resp., $\sigma_{0}=\sigma_{n+1}=+\infty$ ). Note that $\mathrm{M}(\sigma)=\mathrm{V}(\sigma)+1$ and

$$
\sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\mathrm{V}(\sigma)} u_{2}^{\mathrm{M}(\sigma)} u_{3}^{\mathrm{da}(\sigma)} u_{4}^{\mathrm{dd}(\sigma)}=\sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\widetilde{\mathrm{M}}(\sigma)} u_{2}^{\widetilde{\mathrm{V}}(\sigma)} u_{3}^{\tilde{\mathrm{dd}}(\sigma)} u_{4}^{\tilde{\mathrm{d}}(\sigma)}
$$

Ji [10] introduced a refinement of $A_{n}(x, y \mid \alpha, \beta)$ as

$$
P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right):=\sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\mathrm{V}(\sigma)} u_{2}^{\mathrm{M}(\sigma)-1} u_{3}^{\mathrm{da}(\sigma)} u_{4}^{\mathrm{dd}(\sigma)} \alpha^{\mathrm{lma}(\sigma)-1} \beta^{\mathrm{rma}(\sigma)-1}
$$

and proved the following generalization of (1.3) using Chen's context-free grammar.
Theorem 1.1 (Ji [10, Thm. 1.4]). We have

$$
\sum_{n \geq 0} P_{n+1}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right) \frac{t^{n}}{n!}=(1+y F(x, y ; t))^{\frac{\alpha+\beta}{2}}(1+x F(x, y ; t))^{\frac{\alpha+\beta}{2}} e^{\frac{1}{2}(\beta-\alpha)\left(u_{4}-u_{3}\right) t}
$$

where $x+y=u_{3}+u_{4}$ and $x y=u_{1} u_{2}$.
When $\alpha=\beta=1$, Theorem 1.1 reduces to another generating function formula of Carlitz and Scoville [4], which is equivalent to

$$
\begin{equation*}
\sum_{n \geq 1} \sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\mathrm{V}(\sigma)} u_{2}^{\mathrm{M}(\sigma)-1} u_{3}^{\mathrm{da}(\sigma)} u_{4}^{\mathrm{dd}(\sigma)} \frac{t^{n}}{n!}=F(x, y ; t) \tag{1.5}
\end{equation*}
$$

where $x+y=u_{3}+u_{4}$ and $x y=u_{1} u_{2}$. A grammatical proof of (1.5) was provided by Fu [7].
Let us enter the world of $q$-series. For an integer $n \geq 0$, let $[n]_{q}!:=\prod_{i=1}^{n}\left(1+q+\cdots+q^{i-1}\right)$ be the $q$-analog of $n!$. Introduce a classical $q$-analog of the exponential function by

$$
\exp _{q}(t):=\sum_{n \geq 0} \frac{t^{n}}{[n]_{q}!}
$$

Stanley (see [14, Sec. 6.4]) proved the following $q$-analog of (1.2)

$$
\begin{equation*}
1+\sum_{n \geq 1} \sum_{\sigma \in \mathfrak{S}_{n}} x^{\operatorname{des}(\sigma)+1} q^{\operatorname{inv}(\sigma)} \frac{t^{n}}{[n]_{q}!}=\frac{1-x}{1-x \exp _{q}(t(1-x))} \tag{1.6}
\end{equation*}
$$

where $\operatorname{inv}(\sigma):=\left|\left\{(i, j) \in[n]^{2}: i<j, \sigma_{i}>\sigma_{j}\right\}\right|$ is the number of inversions of $\sigma$. Pan and Zeng [13] proved (see also [6,19] for alternative proofs) the following $q$-analog of (1.5), which refines Stanley's formula (1.6).

Theorem 1.2 (Pan and Zeng). We have

$$
\sum_{n \geq 1} \sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\tilde{\mathrm{V}}(\sigma)} u_{2}^{\tilde{\mathrm{M}}(\sigma)} u_{3}^{\tilde{\operatorname{da}}(\sigma)} u_{4}^{\tilde{\operatorname{dd}}(\sigma)} q^{\operatorname{inv}(\sigma)} \frac{t^{n}}{[n]_{q}!}=F\left(x, y, u_{4}, q ; t\right),
$$

where

$$
\begin{equation*}
F(x, y, u, q ; t):=u_{1} \frac{\exp _{q}((x-u) t)-\exp _{q}((y-u) t)}{x \exp _{q}((y-u) t)-y \exp _{q}((x-u) t)} \tag{1.7}
\end{equation*}
$$

$x+y=u_{3}+u_{4}$ and $x y=u_{1} u_{2}$.

Inspired by these work mentioned above, it is natural to ask for a $q$-analog of Theorem 1.1. For this purpose, we introduce the $q$-analog of $P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right)$ by

$$
P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta ; q\right):=\sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\mathrm{V}(\sigma)} u_{2}^{\mathrm{M}(\sigma)-1} u_{3}^{\mathrm{da}(\sigma)} u_{4}^{\mathrm{dd}(\sigma)} \alpha^{\operatorname{lma}(\sigma)-1} \beta^{\mathrm{rma}(\sigma)-1} q^{\operatorname{inv}(\sigma)} .
$$

Our main result is the following $q$-analog of Theorem 1.1, which will be proved via Gessel's $q$-compositional formula [9].

Theorem 1.3. Let $F(x, y, u, q ; t)$ be defined in (1.7). Then

$$
\begin{equation*}
\sum_{n \geq 0} P_{n+1}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta ; q\right) \frac{t^{n}}{[n]_{q}!}=\prod_{k=0}^{\infty} G_{k}\left(x, y, u_{1}, u_{2}, u_{3}, u_{4} ; t\right) \tag{1.8}
\end{equation*}
$$

where $x+y=u_{3}+u_{4}, x y=u_{1} u_{2}$ and

$$
\begin{aligned}
G_{k}\left(x, y, u_{1}, u_{2}, u_{3}, u_{4} ; t\right):= & {\left[1-t \alpha q^{k}(1-q)\left(u_{3}+u_{2} F\left(x, y, u_{4}, q ; t q^{k+1}\right)\right)\right]^{-1} } \\
& \times\left[1-\frac{t \beta}{q^{k}}(q-1)\left(u_{4}+u_{2} F\left(x, y, u_{3}, \frac{1}{q} ; \frac{t}{q^{k}}\right)\right)\right]^{-1}
\end{aligned}
$$

We will show that Theorem 1.3 reduces to Theorem 1.1 when $q \rightarrow 1$. As shown by Ji [10], Theorem 1.1 has many nice applications, one of which is the $\gamma$-positivity of the Stirling-Eulerian polynomials $A_{n}(x, y \mid \alpha, \beta)$ that we recall below.

If $h(x, y)$ is symmetry and homogeneous of degree $n$, then it can be expanded as

$$
h(x, y)=\sum_{k=0}^{\lfloor n / 2\rfloor} \gamma_{k}(x y)^{k}(x+y)^{n-2 k}
$$

Moreover, if $\gamma_{k} \geq 0$ for all $k$, then $h(x, y)$ is said to be $\gamma$-positive. One of the typical examples arising from permutation statistics due to Foata and Schüzenberger is the bivariate Eulerian polynomials $A_{n}(x, y):=\sum_{\sigma \in \mathfrak{S}_{n}} x^{\operatorname{asc}(\sigma)} y^{\operatorname{des}(\sigma)}$; see the survey of Athanasiadis [3] for more information.

Using Theorem 1.1, Ji proved the following refined $\gamma$-positivity expansion.
Theorem $1.4\left(\mathrm{Ji}\left[10\right.\right.$, Theorem 1.9]). Let $\mathcal{P}_{n, k}$ be the set of $\sigma \in \mathfrak{S}_{n}$ such that $\widetilde{\mathrm{M}}(\sigma)=k$. Then

$$
\begin{equation*}
A_{n}\left(x, y \left\lvert\, \frac{\alpha+\beta}{2}\right., \frac{\alpha+\beta}{2}\right)=\sum_{k=0}^{\lfloor(n-1) / 2\rfloor} \gamma_{n, k}(\alpha, \beta)(x y)^{k}(x+y)^{n-2 k-1}, \tag{1.9}
\end{equation*}
$$

where

$$
\gamma_{n, k}(\alpha, \beta)=2^{2 k+1-n} \sum_{\sigma \in \mathcal{P}_{n, k}} \alpha^{\operatorname{lmi}(\sigma)-1} \beta^{\operatorname{rmi}(\sigma)-1} .
$$

On the other hand, Ji and Lin [11] proved the $\alpha=\beta$ case combinatorially via introducing a group action on permutations, namely,

$$
\begin{equation*}
A_{n}(x, y \mid \alpha, \alpha)=\sum_{k=0}^{\lfloor(n-1) / 2\rfloor} \gamma_{n, k}(\alpha)(x y)^{k}(x+y)^{n-2 k-1} \tag{1.10}
\end{equation*}
$$

where

$$
\gamma_{n, k}(\alpha)=2^{2 k+1-n} \sum_{\sigma \in \mathcal{P}_{n, k}} \alpha^{\operatorname{lmi}(\sigma)+\operatorname{rmi}(\sigma)-2}
$$

Comparing (1.10) with (1.9) we get the following identity.
Theorem 1.5. For $n \geq 1$, we have

$$
\begin{equation*}
\sum_{\sigma \in \mathcal{P}_{n, k}}(2 \alpha)^{\operatorname{lmi}(\sigma)-1}(2 \beta)^{\mathrm{rmi}(\sigma)-1}=\sum_{\sigma \in \mathcal{P}_{n, k}}(\alpha+\beta)^{\operatorname{lmi}(\sigma)+\mathrm{rmi}(\sigma)-2} . \tag{1.11}
\end{equation*}
$$

We will introduce a group action on permutations to prove Theorem 1.5 combinatorially, which provides a combinatorial approach to (1.9) in view of the group action proof of (1.10) in [11].

The rest of this paper is organized as follows. In Section 2, we recall a $q$-analog of the exponential formula from [9] and use it to prove Theorem 1.3. In Section 3, we show that Theorem 1.3 can be described as an integral formula which reduces to Theorem 1.1 when $q \rightarrow 1$. The combinatorial proof of Theorem 1.5 is proved in Section 4 via introducing a new group action on permutations.

## 2. Gessel's $q$-compositional formula and proof of Theorem 1.3

2.1. Gessel's $q$-compositional formula. Throughout this paper, let $R$ be a ring of polynomials in some finite indeterminates with rational coefficients. The Eulerian differential operator $\delta_{t}($ see [2]) is defined by

$$
\delta_{t}(f(t))=\frac{f(q t)-f(t)}{(q-1) t}
$$

for any function $f(t) \in R[[t]]$ in the ring of formal power series in $t$ over $R$. Note that for $q=1, \delta_{t}$ reduces to the ordinary derivative. For example, we have

$$
\begin{equation*}
\delta_{t}\left(t^{n} /[n]_{q}!\right)=t^{n-1} /[n-1]_{q}!\quad \text { for } n \geq 1 \tag{2.1}
\end{equation*}
$$

For the sake of convenience, we shall often write $f^{\prime}$ for $\delta_{t}(f)$.
Following Gessel [9], we define the following $q$-analog of the map $f \mapsto f^{k} / k$ ! for exponential generating functions.
Definition 2. Suppose that $f(0)=0$. Define $f^{[k]}$ by $f^{[0]}=1$ and for $k \geq 1$,

$$
\begin{equation*}
\delta_{t}\left(f^{[k]}\right)=f^{\prime} \cdot f^{[k-1]} \text { with } f^{[k]}(0)=0 \tag{2.2}
\end{equation*}
$$

If we write $f^{[k]}(t)=\sum_{n \geq 0} f_{n}^{(k)} \frac{t^{n}}{[n] q!}$ for $k \geq 1$, then Eq. (2.2) is equivalent to the recursion

$$
f_{n+1}^{(k)}=\sum_{i=0}^{n}\left[\begin{array}{c}
n \\
i
\end{array}\right]_{q} f_{n-i+1}^{(1)} f_{i}^{(k-1)}
$$

where $\left[\begin{array}{c}n \\ i\end{array}\right]_{q}:=\frac{[n]_{q}!}{[i]_{q}![n-i]_{q}!}$ are the $q$-binomial coefficients.
Definition 3. Suppose that $f(0)=0$ and $g(t)=\sum_{n \geq 0} g_{n} \frac{t^{n}}{[n] q!}$. Define the $q$-composition $g[f]$ by

$$
g[f]:=\sum_{n \geq 0} g_{n} f^{[n]}
$$

Note that $t^{[k]}=t^{k} /[k]_{q}$ ! and so $g[t]=g(t)$. Gessel [9] proved the following $q$-compositional formula, which $\operatorname{express} \exp _{q}[f]$ as an infinite product.
Theorem 2.1 (Gessel [9]). Suppose that $f(0)=0$. Then

$$
\begin{equation*}
\exp _{q}[f]=\prod_{k=0}^{\infty}\left(1-t q^{k}(1-q) f^{\prime}\left(q^{k} t\right)\right)^{-1} \tag{2.3}
\end{equation*}
$$

A permutation is basic if it begins with its greatest element. Denote by $\mathfrak{B}_{n}$ the set of all basic permutations in $\mathfrak{S}_{n}$. For a permutation $\sigma$ with $\operatorname{lma}(\sigma)=k$, there exists a unique decomposition of $\sigma$ into basic components as

$$
\begin{equation*}
\sigma=\beta_{1} \beta_{2} \cdots \beta_{k} \tag{2.4}
\end{equation*}
$$

where

- each $\beta_{i}$ is basic;
- and the first letter of each $\beta_{i}$ is a left-to-right maximum of $\sigma$.

Such a decomposition of $\sigma$ is called the basic decomposition of $\sigma$ in [9]. For example, $\sigma=2164573$ has the basic decomposition $\beta_{1}=21, \beta_{2}=645$ and $\beta_{3}=73$.

Given any permutation $\sigma$ with $n$ distinct letters, let $\operatorname{red}(\sigma)$ be the permutation in $\mathfrak{S}_{n}$ obtained from $\sigma$ by replacing its $i$-th smallest element by $i$ for $1 \leq i \leq n$. For example, $\operatorname{red}(8425)=4213$. A function $\omega$ from the set of all permutations to a commutative algebra over the rationals is called multiplicative if for all permutations $\sigma$ :
(i) $\omega(\sigma)=\omega(\operatorname{red}(\sigma))$;
(ii) If $\beta_{1} \beta_{2} \cdots \beta_{k}$ is the basic decomposition of $\sigma$, then $\omega(\sigma)=\omega\left(\beta_{1}\right) \omega\left(\beta_{2}\right) \cdots \omega\left(\beta_{k}\right)$. For instance, the function $\omega(\sigma)=x^{\operatorname{lma}(\sigma)}$ is multiplicative.
Theorem 2.2 (Gessel [9]). Let $\omega$ be a multiplicative function. Suppose $g_{n}=\sum_{\sigma \in \mathfrak{S}_{n}} \omega(\sigma) q^{\operatorname{inv}(\sigma)}$ and $f_{n}=\sum_{\beta \in \mathfrak{B}_{n}} \omega(\beta) q^{\operatorname{inv}(\beta)}$. Then

$$
\begin{equation*}
\sum_{n \geq 0} g_{n} \frac{t^{n}}{[n]_{q}!}=\exp _{q}\left[\sum_{n \geq 1} f_{n} \frac{t^{n}}{[n]_{q}!}\right] \tag{2.5}
\end{equation*}
$$

### 2.2. Proof of Theorem 1.3.

Definition 4. For $\sigma \in \mathfrak{S}_{n}$, let $\mathrm{M}_{0}(\sigma)$, $\mathrm{V}_{0}(\sigma)$, da $\mathrm{da}_{0}(\sigma)$ and $\operatorname{dd}_{0}(\sigma)$ (resp., $\mathrm{M}_{\infty}(\sigma)$, $\mathrm{V}_{\infty}(\sigma)$, $\mathrm{da}_{\infty}(\sigma)$ and $\left.\mathrm{dd}_{\infty}(\sigma)\right)$ denote respectively the numbers of peaks, valleys, double ascents and double descents in $\sigma$ with boundary conditions $\sigma_{0}=0$ and $\sigma_{n+1}=+\infty$ (resp., $\sigma_{0}=+\infty$ and $\sigma_{n+1}=0$ ). Introduce two weighted functions by

$$
\omega_{0}(\sigma)=u_{1}^{\mathrm{V}_{0}(\sigma)} u_{2}^{\mathrm{M}_{0}(\sigma)} u_{3}^{\mathrm{da}_{0}(\sigma)} u_{4}^{\mathrm{dd}_{0}(\sigma)} \alpha^{\operatorname{lma}(\sigma)}
$$

and

$$
\omega_{\infty}(\sigma)=u_{1}^{\mathrm{V}_{\infty}(\sigma)} u_{2}^{\mathrm{M} \infty(\sigma)} u_{3}^{\mathrm{da}_{\infty}(\sigma)} u_{4}^{\mathrm{dd}_{\infty}(\sigma)} \beta^{\mathrm{rma}(\sigma)} .
$$

The following observation can be checked routinely.
Lemma 2.3. The function $\omega_{0}$ is multiplicative.
We are now in position to prove Theorem 1.3.

Proof of Theorem 1.3. Throughout the proof, we assume that $x+y=u_{3}+u_{4}$ and $x y=u_{1} u_{2}$. Let

$$
L_{n}\left(u_{3}, u_{4}, \alpha, q\right):=\sum_{\sigma \in \mathfrak{S}_{n}} \omega_{0}(\sigma) q^{\operatorname{inv}(\sigma)} \quad \text { and } \quad B_{n}(\alpha, q):=\sum_{\sigma \in \mathfrak{B}_{n}} \omega_{0}(\sigma) q^{\operatorname{inv}(\sigma)}
$$

It follows from Lemma 2.3 and Theorem 2.2 that

$$
\begin{equation*}
\sum_{n \geq 0} L_{n}\left(u_{3}, u_{4}, \alpha, q\right) \frac{t^{n}}{[n]_{q}!}=\exp _{q}\left[\sum_{n \geq 1} B_{n}(\alpha, q) \frac{t^{n}}{[n]_{q}!}\right] \tag{2.6}
\end{equation*}
$$

As $B_{1}(\alpha, q)=u_{3} \alpha$ and for $n \geq 2$,

$$
B_{n}(\alpha, q)=u_{2} \alpha q^{n-1} \sum_{\sigma \in \mathfrak{S}_{n-1}} u_{1}^{\tilde{\mathrm{V}}(\sigma)} u_{2}^{\tilde{\mathrm{M}}(\sigma)} u_{3}^{\tilde{\mathrm{da}}(\sigma)} u_{4}^{\tilde{\operatorname{dd}}(\sigma)} q^{\operatorname{inv}(\sigma)}
$$

by (2.1) we have

$$
\begin{aligned}
\delta_{t}\left(\sum_{n \geq 1} B_{n}(\alpha, q) \frac{t^{n}}{[n]_{q}!}\right) & =\sum_{n \geq 1} B_{n}(\alpha, q) \frac{t^{n-1}}{[n-1]_{q}!} \\
& =u_{3} \alpha+u_{2} \alpha \sum_{n \geq 1} \sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\widetilde{\mathrm{V}}(\sigma)} u_{2}^{\tilde{\mathrm{M}}(\sigma)} u_{3}^{\tilde{\mathrm{d}}(\sigma)} u_{4}^{\tilde{\operatorname{dd}}(\sigma)} q^{\operatorname{inv}(\sigma)} \frac{(t q)^{n}}{[n]_{q}!} \\
& =u_{3} \alpha+u_{2} \alpha F\left(x, y, u_{4}, q ; t q\right)
\end{aligned}
$$

in view of Theorem 1.2. It then follows from Theorem 2.1 and Eq. (2.6) that

$$
\begin{equation*}
\sum_{n \geq 0} L_{n}\left(u_{3}, u_{4}, \alpha, q\right) \frac{t^{n}}{[n]_{q}!}=\prod_{k \geq 0}\left[1-t \alpha q^{k}(1-q)\left(u_{3}+u_{2} F\left(x, y, u_{4}, q ; t q^{k+1}\right)\right)\right]^{-1} \tag{2.7}
\end{equation*}
$$

On the other hand, we need to compute the exponential generating function for

$$
R_{n}\left(u_{3}, u_{4}, \beta, q\right):=\sum_{\sigma \in \mathfrak{G}_{n}} \omega_{\infty}(\sigma) q^{\operatorname{inv}(\sigma)}
$$

For $\sigma \in \mathfrak{S}_{n}$, let $\sigma^{r}:=\sigma_{n} \sigma_{n-1} \cdots \sigma_{1}$ be the reversal of $\sigma$. As

$$
\mathrm{V}_{\infty}\left(\sigma^{r}\right)=\mathrm{V}_{0}(\sigma), \mathrm{M}_{\infty}\left(\sigma^{r}\right)=\mathrm{M}(\sigma), \mathrm{da}_{\infty}\left(\sigma^{r}\right)=\operatorname{dd}_{0}(\sigma), \operatorname{dd}_{\infty}\left(\sigma^{r}\right)=\mathrm{da}_{0}(\sigma)
$$

and

$$
\operatorname{rma}\left(\sigma^{r}\right)=\operatorname{lma}(\sigma), \quad \operatorname{inv}\left(\sigma^{r}\right)=\binom{n}{2}-\operatorname{inv}(\sigma)
$$

we have

$$
\begin{aligned}
\sum_{n \geq 0} R_{n}\left(u_{3}, u_{4}, \beta, q\right) \frac{t^{n}}{[n]_{q}!} & =\sum_{n \geq 0} q^{\binom{n}{2}} L_{n}\left(u_{4}, u_{3}, \beta, q^{-1}\right) \frac{t^{n}}{[n]_{q}!} \\
& =\sum_{n \geq 0} L_{n}\left(u_{4}, u_{3}, \beta, q^{-1}\right) \frac{t^{n}}{[n]_{q^{-1}}!}
\end{aligned}
$$

It then follows from (2.7) that

$$
\begin{equation*}
\sum_{n \geq 0} R_{n}\left(u_{3}, u_{4}, \beta, q\right) \frac{t^{n}}{[n]_{q}!}=\prod_{k \geq 0}\left[1-\frac{t \beta}{q^{k}}\left(1-\frac{1}{q}\right)\left(u_{4}+u_{2} F\left(x, y, u_{3}, \frac{1}{q} ; \frac{t}{q^{k+1}}\right)\right)\right]^{-1} \tag{2.8}
\end{equation*}
$$

It is known [17, Prop 1.3.17] that $\left[\begin{array}{l}n \\ k\end{array}\right]_{q}$ has the following interpretation

$$
\left[\begin{array}{l}
n \\
k
\end{array}\right]_{q}=\sum_{(\mathcal{A}, \mathcal{B})} q^{\operatorname{inv}(\mathcal{A}, \mathcal{B})}
$$

summed over all ordered partitions $(\mathcal{A}, \mathcal{B})$ of $[n]$ such that $|\mathcal{A}|=k$. Let

$$
\mathfrak{S}_{n+1, k+1}:=\left\{\sigma \in \mathfrak{S}_{n+1}: \sigma_{k+1}=n+1\right\}
$$

As any permutation $\sigma \in \mathfrak{S}_{n+1, k+1}$ can be written as $\sigma=\sigma_{L}(n+1) \sigma_{R}$ with $\sigma_{L}=\sigma_{1} \cdots \sigma_{k}$ and $\sigma_{R}=\sigma_{k+2} \cdots \sigma_{n+1}$, we have

$$
\begin{aligned}
& \sum_{\sigma \in \mathfrak{G}_{n+1, k+1}} u_{1}^{\mathrm{V}(\sigma)} u_{2}^{\mathrm{M}(\sigma)-1} u_{3}^{\mathrm{da}(\sigma)} u_{4}^{\mathrm{dd}(\sigma)} \alpha^{\operatorname{lma}(\sigma)-1} \beta^{\mathrm{rma}(\sigma)-1} q^{\operatorname{inv}(\sigma)} \\
= & {\left[\begin{array}{l}
n \\
k
\end{array}\right]_{q} q^{n-k} L_{k}\left(u_{3}, u_{4}, \alpha, q\right) R_{n-k}\left(u_{3}, u_{4}, \beta, q\right) }
\end{aligned}
$$

in view of the above interpretation of $\left[\begin{array}{l}n \\ k\end{array}\right]_{q}$. Thus,

$$
P_{n+1}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta ; q\right)=\sum_{k=0}^{n}\left[\begin{array}{l}
n \\
k
\end{array}\right]_{q} q^{n-k} L_{k}\left(u_{3}, u_{4}, \alpha, q\right) R_{n-k}\left(u_{3}, u_{4}, \beta, q\right)
$$

which in terms of exponential generating function gives
$\sum_{n \geq 0} P_{n+1}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta ; q\right) \frac{t^{n}}{[n]_{q}!}=\left(\sum_{n \geq 0} L_{n}\left(u_{3}, u_{4}, \alpha, q\right) \frac{t^{n}}{[n]_{q}!}\right)\left(\sum_{n \geq 0} R_{n}\left(u_{3}, u_{4}, \beta, q\right) \frac{(t q)^{n}}{[n]_{q}!}\right)$.
Substituting (2.7) and (2.8) into the above identity proves Theorem 1.3.

## 3. A new proof of Theorem 1.1

For any $f(t) \in R[[t]]$, define the $q$-integral (see [8, Section 1.11]) of $f$ by

$$
\begin{equation*}
\int_{0}^{t} f(x) d_{q} x:=t(1-q) \sum_{n \geq 0} f\left(q^{n} t\right) q^{n} \tag{3.1}
\end{equation*}
$$

As $\lim _{q \rightarrow 1} \int_{0}^{t} x^{k} d_{q} x=t^{k+1} /(k+1)$ for $k \geq 0$, we have

$$
\begin{equation*}
\lim _{q \rightarrow 1} \int_{0}^{t} f(x) d_{q} x=\int_{0}^{t} f(x) d x \tag{3.2}
\end{equation*}
$$

Our main result Theorem 1.3 can also be described as an integral formula.
Theorem 3.1. We have

$$
\begin{aligned}
& \sum_{n \geq 0} P_{n+1}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta ; q\right) \frac{t^{n}}{[n]_{q}!} \\
= & \exp \left(\int_{0}^{t} \frac{\ln \left[1-(1-q) z \alpha\left(u_{3}+u_{2} F(z q)\right)\right]^{-1}}{(1-q) z} d_{q} z+\int_{0}^{t} \frac{\ln \left[1-(q-1) z \beta\left(u_{4}+u_{2} \tilde{F}(z)\right)\right]^{-1}}{\left(1-\frac{1}{q}\right) z} d_{\frac{1}{q}} z\right),
\end{aligned}
$$

with $x+y=u_{3}+u_{4}, x y=u_{1} u_{2}$,

$$
\begin{equation*}
F(t):=F\left(x, y, u_{4}, q ; t\right) \quad \text { and } \quad \tilde{F}(t):=F\left(x, y, u_{3}, \frac{1}{q} ; t\right) \tag{3.3}
\end{equation*}
$$

Proof. As $\ln (1-t)^{-1}=\sum_{n \geq 1} \frac{t^{n}}{n}$, we have

$$
\begin{align*}
& \prod_{k \geq 0}\left[1-t \alpha q^{k}(1-q)\left(u_{3}+u_{2} F\left(t q^{k+1}\right)\right)\right]^{-1} \\
= & \exp \left(\ln \left(\prod_{k \geq 0}\left[1-t \alpha q^{k}(1-q)\left(u_{3}+u_{2} F\left(t q^{k+1}\right)\right)\right]^{-1}\right)\right) \\
= & \exp \left(\sum_{k \geq 0} \ln \left[1-t \alpha q^{k}(1-q)\left(u_{3}+u_{2} F\left(t q^{k+1}\right)\right)\right]^{-1}\right) \\
= & \exp \left(\sum_{k \geq 0} \sum_{n \geq 1} \frac{\left[t \alpha q^{k}(1-q)\left(u_{3}+u_{2} F\left(t q^{k+1}\right)\right)\right]^{n}}{n}\right) \\
= & \exp \left(\sum_{n \geq 1} \frac{(1-q)^{n-1}}{n}(1-q) t \sum_{k \geq 0} q^{k}\left(t q^{k}\right)^{n-1}\left(u_{3} \alpha+u_{2} \alpha F\left(t q^{k+1}\right)\right)^{n}\right) \\
= & \exp \left(\sum_{n \geq 1} \frac{(1-q)^{n-1}}{n} \int_{0}^{t} z^{n-1}\left(u_{3} \alpha+u_{2} \alpha F(z q)\right)^{n} d_{q} z\right) \quad \text { By Def. }  \tag{3.1}\\
= & \exp \left(\int_{0}^{t} \sum_{n \geq 1}^{\left[(1-q) z\left(u_{3} \alpha+u_{2} \alpha F(z q)\right)\right]^{n}} d_{q} z\right) \\
= & \exp \left(\int_{0}^{t} \frac{\ln [1-(1-q) z}{} \frac{\left[1-q\left(u_{3}+u_{2} F(z q)\right)\right]^{-1}}{(1-q) z} d_{q} z\right) .
\end{align*}
$$

Similarly, we have
$\prod_{k \geq 0}\left[1-\frac{t \beta}{q^{k}}(q-1)\left(u_{4}+u_{2} \tilde{F}\left(t q^{-k}\right)\right)\right]^{-1}=\exp \left(\int_{0}^{t} \frac{\ln \left[1-(q-1) z \beta\left(u_{4}+u_{2} \tilde{F}(z)\right)\right]^{-1}}{\left(1-\frac{1}{q}\right) z} d_{\frac{1}{q}} z\right)$.
The desired integral formula then follows from Theorem 1.3.
Next, we show that our integral formula in Theorem 3.1 reduces to Theorem 1.1 when $q \rightarrow 1$. We need the following simple lemma.

Lemma 3.2. Let $F(x, y ; t)$ be defined in (1.4). Then,

$$
\begin{equation*}
\int_{0}^{t} x y F(x, y ; z) d z=\ln \left(\frac{x-y}{x e^{y t}-y e^{x t}}\right) . \tag{3.4}
\end{equation*}
$$

Proof. We have

$$
\frac{d\left(-\ln \left[x e^{y t}-y e^{x t}\right]\right)}{d t}=\frac{x y\left(e^{x t}-e^{y t}\right)}{x e^{y t}-y e^{x t}}=x y F(x, y ; t),
$$

from which the result then follows.

We are now ready for a new proof of Theorem 1.1.
A new proof of Theorem 1.1. When $q \rightarrow 1$, the two infinitesimal quantities

$$
\ln \left[1-(1-q) t \alpha\left(u_{3}+u_{2} F(t q)\right)\right] \quad \text { and } \quad(1-q) t \alpha\left(u_{3}+u_{2} F(t q)\right)
$$

are equivalent, and so are

$$
\ln \left[1-(q-1) t \beta\left(u_{4}+u_{2} \tilde{F}(t)\right)\right] \quad \text { and } \quad(q-1) t \beta\left(u_{4}+u_{2} \tilde{F}(t)\right)
$$

where $F(t)$ and $\tilde{F}(t)$ are defined in (3.3). Thus, if we let $q \rightarrow 1$ in Theorem 3.1, then by (3.2) we have

$$
\begin{aligned}
& \sum_{n \geq 0} P_{n+1}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right) \frac{t^{n}}{n!} \\
= & \exp \left(\int_{0}^{t} \alpha\left(u_{3}+u_{2} F\left(x, y, u_{4}, 1 ; z\right)\right) d z+\int_{0}^{t} \beta\left(u_{4}+u_{2} F\left(x, y, u_{3}, 1 ; z\right)\right) d z\right) \\
= & \exp \left(\int_{0}^{t} \alpha\left(u_{3}+x y F(x, y ; z)\right) d z+\int_{0}^{t} \beta\left(u_{4}+x y F(x, y ; z)\right) d z\right)
\end{aligned}
$$

with $x y=u_{1} u_{2}$ and $x+y=u_{3}+u_{4}$. Using (3.4) we get

$$
\sum_{n \geq 0} P_{n+1}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right) \frac{t^{n}}{n!}=e^{\left(u_{3} \alpha+u_{4} \beta\right) t}\left(\frac{x-y}{x e^{y t}-y e^{x t}}\right)^{\alpha+\beta}
$$

completing the proof.

## 4. Combinatorics of the $\gamma$-Positivity of Stirling-Eulerian polynomials

This section aims to prove Theorem 1.5 combinatorially by introducing a new group action on permutations.

For $\sigma \in \mathfrak{S}_{n}$ with $\operatorname{lmi}(\sigma)-1=k$ and $\operatorname{rmi}(\sigma)-1=l$, there exists a unique decomposition of $\sigma$ as

$$
\sigma=\alpha_{1} \alpha_{2} \cdots \alpha_{k} 1 \beta_{1} \beta_{2} \cdots \beta_{l}
$$

where

- the first letter of each $\alpha_{i}(1 \leq i \leq k)$, which is smallest inside $\alpha_{i}$, is a left-to-right minimum of $\sigma$;
- and the last letter of each $\beta_{i}(1 \leq i \leq l)$, which is smallest inside $\beta_{i}$, is a right-to-left minimum of $\sigma$.
We call this decomposition the bi-basic decomposition of $\sigma$ and each $\alpha_{i}$ or $\beta_{i}$ a block of $\sigma$. An example of the bi-basic decomposition is

$$
\begin{equation*}
\sigma=510|2124136| \mathbf{1}|11 \mathbf{3}| 9815 \mathbf{7} \mid \mathbf{1 4} \tag{4.1}
\end{equation*}
$$

where blocks are separated by bars. For each word $w=w_{1} w_{2} \cdots w_{d}$, let $w^{r}:=w_{d} w_{d-1} \cdots w_{1}$ be the reversal of $w$. For each $x \in[n]$, we define $\psi_{x}(\sigma)$ according to the following cases
(1) if $x$ is the first letter of $\alpha_{i}$ for some $i$, then $\psi_{x}(\sigma)$ is obtained from $\sigma$ by deleting the block $\alpha_{i}$ and then inserting $\alpha_{i}^{r}$ in some proper gap between blocks so that $x$ becomes an additional right-to-left minimum;
(2) if $x$ is the first letter of $\beta_{i}$ for some $i$, then $\psi_{x}(\sigma)$ is obtained from $\sigma$ by deleting the block $\beta_{i}$ and then inserting $\beta_{i}^{r}$ in some proper gap between blocks so that $x$ becomes an additional left-to-right minimum;
(3) otherwise, set $\psi_{x}(\sigma)=\sigma$.

Taking $\sigma$ as in (4.1), then

$$
\psi_{2}(\sigma)=510|\mathbf{1}| 613412 \mathbf{2}|11 \mathbf{3}| 9815 \mathbf{7} \mid \mathbf{1 4}
$$

and

$$
\psi_{3}(\sigma)=510|\mathbf{3} 11| 2124136|\mathbf{1}| 9815 \mathbf{7} \mid \mathbf{1 4}
$$

It is clear that the map $\psi_{x}$ is an involution acting on $\mathfrak{S}_{n}$, and for all $x, y \in[n], \psi_{x}$ and $\psi_{y}$ commute. The following lemma is evident from the construction of $\psi_{x}$.

Lemma 4.1. If $x$ is a left-to-right (resp., right-to-left) minimum of $\sigma$, then $x$ becomes a right-to-left (resp., left-to-right) minimum of $\psi_{x}(\sigma)$. Moreover, $\psi_{x}$ preserves the peak statistic " ${ }^{-1}$ ".

We are now ready for the combinatorial proof of Theorem 1.5.
Proof of Theorem 1.5. Denote by $\operatorname{LMI}(\sigma)$ and $\operatorname{RMI}(\sigma)$ the set of left-to-right minima and the set of right-to-left minima of $\sigma$ other than 1 , respectively. In order to interpret the left-hand side of (1.11), we introduce the set

$$
\widetilde{\mathcal{P}}_{n, k}=\left\{(\sigma, S): \sigma \in \mathcal{P}_{n, k}, S \subseteq \operatorname{LMI}(\sigma) \cup \operatorname{RMI}(\sigma)\right\}
$$

of marked permutations, where $\mathcal{P}_{n, k}:=\left\{\sigma \in \mathfrak{S}_{n} \mid \widetilde{\mathrm{M}}(\sigma)=k\right\}$. Thus,

$$
\begin{equation*}
\sum_{\sigma \in \mathcal{P}_{n, k}}(2 \alpha)^{\operatorname{lmi}(\sigma)-1}(2 \beta)^{\mathrm{rmi}(\sigma)-1}=\sum_{(\sigma, S) \in \widetilde{\mathcal{P}}_{n, k}} \alpha^{\operatorname{lmi}(\sigma)-1} \beta^{\mathrm{rmi}(\sigma)-1} \tag{4.2}
\end{equation*}
$$

For $x \in[n]$ and $(\sigma, S) \in \widetilde{\mathcal{P}}_{n, k}$, we define the action $\Psi_{x}$ on $\widetilde{\mathcal{P}}_{n, k}$ as

$$
\Psi_{x}(\sigma, S)= \begin{cases}\left(\psi_{x}(\sigma), S \triangle\{x\}\right), & \text { if } x \in \operatorname{LMI}(\sigma) \cup \operatorname{RMI}(\sigma) \\ (\sigma, S), & \text { otherwise }\end{cases}
$$

It is routine to check that all $\Psi_{x}$ 's are involutions and commute. Therefore, for any $X \subseteq[n]$ we can define the function $\Psi_{X}: \widetilde{\mathcal{P}}_{n, k} \rightarrow \widetilde{\mathcal{P}}_{n, k}$ by $\Psi_{X}=\prod_{x \in X} \Psi_{x}$, where multiplication is the composition of functions. Hence the group $\mathbb{Z}_{2}^{n}$ acts on $\widetilde{\mathcal{P}}_{n, k}$ via the function $\Psi_{X}$. Let $\operatorname{Orb}(\sigma, S)$ be the orbit of $(\sigma, S)$ under this action. Inside each orbit $\operatorname{Orb}(\sigma, S)$ there exists a unique element $(\bar{\sigma}, \emptyset)$, where $\bar{\sigma}=\Psi_{S}(\sigma)$. It then follows from Lemma 4.1 that

$$
\sum_{(\pi, T) \in \operatorname{Orb}(\sigma, S)} \alpha^{\operatorname{lmi}(\pi)-1} \beta^{\operatorname{rmi}(\pi)-1}=(\alpha+\beta)^{\operatorname{lmi}(\bar{\sigma})+\operatorname{rmi}(\bar{\sigma})-2}
$$

Summing over all orbits of $\widetilde{\mathcal{P}}_{n, k}$ then results in

$$
\sum_{(\sigma, S) \in \widetilde{\mathcal{P}}_{n, k}} \alpha^{\operatorname{lmi}(\sigma)-1} \beta^{\mathrm{rmi}(\sigma)-1}=\sum_{\sigma \in \mathcal{P}_{n, k}}(\alpha+\beta)^{\operatorname{lmi}(\sigma)+\mathrm{rmi}(\sigma)-2},
$$

which proves (1.11) in view of (4.2).

As a byproduct of the action $\psi_{x}$, we can also prove the following neat expression for $\gamma_{n, k}(\alpha, \beta)$.
Theorem 4.2. For $n \geq 1$, we have

$$
\begin{equation*}
\sum_{\sigma \in \mathcal{P}_{n, k}} \alpha^{\operatorname{lmi}(\sigma)-1} \beta^{\mathrm{rmi}(\sigma)-1}=\sum_{\sigma \in \mathcal{\mathcal { L } _ { n - 1 , k }}}(\alpha+\beta)^{\mathrm{rmi}(\sigma)} \tag{4.3}
\end{equation*}
$$

where $\mathcal{L}_{n-1, k}=\left\{\sigma \in \mathfrak{S}_{n-1}: \mathrm{M}_{0}(\sigma)=k\right\}$. Consequently,

$$
\gamma_{n, k}(\alpha, \beta)=2^{2 k+1-n} \sum_{\sigma \in \mathcal{\mathcal { L } _ { n - 1 , k }}}(\alpha+\beta)^{\mathrm{rmi}(\sigma)}
$$

Proof. We consider the function $\psi_{X}: \mathcal{P}_{n, k} \rightarrow \mathcal{P}_{n, k}$ defined by $\psi_{X}=\prod_{x \in X} \psi_{x}$. Then, the group $\mathbb{Z}_{2}^{n}$ acts on $\mathcal{P}_{n, k}$ via the function $\psi_{X}$. Let $\operatorname{Orb}(\sigma)$ be the orbit of $\sigma$ under this action. Inside each orbit $\operatorname{Orb}(\sigma)$ there exists a unique element $\bar{\sigma}$ whose first letter is 1 . It then follows from Lemma 4.1 that

$$
\sum_{\pi \in \operatorname{Orb}(\sigma)} \alpha^{\operatorname{lmi}(\pi)-1} \beta^{\mathrm{rmi}(\pi)-1}=(\alpha+\beta)^{\mathrm{rmi}(\bar{\sigma})-1}
$$

Summing over all orbits of $\mathcal{P}_{n, k}$ then results in

$$
\begin{aligned}
\sum_{\sigma \in \mathcal{P}_{n, k}} \alpha^{\operatorname{lmi}(\sigma)-1} \beta^{\mathrm{rmi}(\sigma)-1} & =\sum_{\substack{\sigma \in \mathcal{P}_{n, k} \\
\sigma_{1}=1}}(\alpha+\beta)^{\mathrm{rmi}(\bar{\sigma})-1} \\
& =\sum_{\sigma \in \mathcal{L}_{n-1, k}}(\alpha+\beta)^{\mathrm{rmi}(\sigma)}
\end{aligned}
$$

where the last equality follows from the simple one-to-one correspondence

$$
\sigma \mapsto\left(\sigma_{2}-1\right)\left(\sigma_{3}-1\right) \cdots\left(\sigma_{n}-1\right)
$$

between $\left\{\sigma \in \mathcal{P}_{n, k}: \sigma_{1}=1\right\}$ and $\mathcal{L}_{n-1, k}$.
The Euler numbers $\left\{E_{n}\right\}_{n \geq 0}$ can be defined by the Taylor expansion

$$
\sec (t)+\tan (t)=\sum_{n \geq 0} E_{n} \frac{t^{n}}{n!}
$$

The numbers $E_{n}$ with even indices and odd indices are known as secant numbers and tangent numbers, respectively. A permutation $\sigma \in \mathfrak{S}_{n}$ is alternating if

$$
\sigma_{1}>\sigma_{2}<\sigma_{3}>\sigma_{4}<\sigma_{5}>\cdots
$$

André [1] proved that $\left|\mathcal{A}_{n}\right|=E_{n}$, where $\mathcal{A}_{n}$ denotes the set of all alternating permutations of length $n$. An immediate consequence of Theorem 4.2 is the following interesting interpretation of the $\alpha$-extension of secant numbers

$$
A_{2 n+1}(-1,1 \mid \alpha / 2, \alpha / 2)=(-1)^{n} \sum_{\sigma \in \mathcal{A}_{2 n}} \alpha^{\mathrm{rmi}(\sigma)}
$$

which was proved by Ji [10] via different approach.

## 5. Concluding remarks

The main achievement of this paper is the computation of the generating function for a $q$ analog of $P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right)$ by using Gessel's $q$-compositional formula. In particular, Ji's formula for $P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right)$ in Theorem 1.1 can be proved directly from Carlitz and Scoville's formula (1.3) by using the classical compositional formula (see [18, Thm. 5.1.4]). However, it should be noted that this approach via the compositional formula does not work for the variation of $P_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right)$ :

$$
\tilde{P}_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right):=\sum_{\sigma \in \mathfrak{S}_{n}} u_{1}^{\tilde{\mathrm{V}}(\sigma)-1} u_{2}^{\tilde{\mathrm{M}}(\sigma)} u_{3}^{\tilde{\mathrm{da}}(\sigma)} u_{4}^{\tilde{\mathrm{dd}}(\sigma)} \alpha^{\operatorname{lma}(\sigma)-1} \beta^{\operatorname{rma}(\sigma)-1}
$$

It remains open to compute the generating function for $\tilde{P}_{n}\left(u_{1}, u_{2}, u_{3}, u_{4} \mid \alpha, \beta\right)$.
A statistic whose distribution over $\mathfrak{S}_{n}$ gives $[n]_{q}$ ! is called a Mahonian statistic. It is well known that 'inv' is a Mahonian statistic on permutations. Another classical Mahonian statistic is the major index (see [17, Sec. 1.3])

$$
\operatorname{maj}(\sigma)=\sum_{\sigma_{i}>\sigma_{i+1}} i
$$

A third Mahonian statistic arising from poset topology was introduced by Shareshian and Wachs [15] as 'ai + des', where ai $(\sigma)$ is the number of admissible inversions of $\sigma$ (see also [12]). The generating functions for the four pairs of Euler-Mahonian statistics in $\{$ exc, des $\} \times\{$ inv, maj $\}$ have already been calculated in the literature; see [15]. In view of Theorem 1.3, it would be interesting to investigate systematically the generating functions for the Stirling-Euler-Mahonian statistics on permutations in

$$
\{\operatorname{lmi}, \text { rmi, lma, rma }, \text { cyc }\} \times\{\text { des }, \text { exc }, \mathrm{M}\} \times\{\text { inv, maj, ai }\}
$$

and their possible refinements. Some related results in this direction have been obtained by Sokal and Zeng [16].

## Statements and Declarations

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.
