# TAKENS' LAST PROBLEM AND STRONG PLURIPOTENCY 

SHIN KIRIKI, XIAOLONG LI, YUSHI NAKANO, TERUHIKO SOMA, AND EDSON VARGAS

#### Abstract

We consider the concept of strong pluripotency of dynamical systems for a hyperbolic invariant set, as introduced in KNS. To the best of our knowledge, for the whole hyperbolic invariant set, the existence of robust strongly pluripotent dynamical systems has not been proven in previous studies. In fact, there is an example of strongly pluripotent dynamical systems in [CV01], but its robustness has not been proven. On the other hand, robust strongly pluripotent dynamical systems for some proper subsets of hyperbolic sets had been found in KS17 KNS. In this paper, we provide a combinatorial way to recognize strongly pluripotent diffeomorphisms in a Newhouse domain and prove that they are $C^{r}$-robust, $2 \leq r<\infty$. More precisely, we prove that there is a 2-dimensional diffeomorphism with a wild Smale horseshoe which has a $C^{r}$ neighborhood $\mathcal{U}_{0}$ where all elements are strongly pluripotent for the whole Smale horseshoe. Moreover, it follows from the result that any property, such as having a non-trivial physical measure supported by the Smale horseshoe or having historic behavior, is $C^{r}$-persistent relative to a dense subset of $\mathcal{U}_{0}$.

## 1. Introduction

In this paper, we consider open subsets of the space Diff ${ }^{r}(M)$ of $C^{r}$ diffeomorphisms endowed with the $C^{r}$ topology, where $M$ is a compact Riemannian surface without boundary. For a large subset of $\operatorname{Diff}^{r}(M)$, those satisfying the Axiom A for example, the topological and statistical behavior of almost every (in the Lebesgue sense) forward orbits agree, that is, they are governed by well-understood measures supported on the topological attractors, see Sin72, Bow75, Rue76.

On the other hand, following Ruelle Rue01, among the possible statistical behaviors, there are points $x \in M$ or its forward orbits which have historic behavior, that is, points $x$ such that the sequence of empirical measures

$$
\begin{equation*}
\delta_{x, f}^{n}=\frac{1}{n} \sum_{i=0}^{n-1} \delta_{f^{i}(x)} \tag{1.1}
\end{equation*}
$$

where $\delta_{f^{i}(x)}$ is the Dirac measure at $f^{i}(x)$, does not converge in the weak* topology, when $n$ goes to infinity. The set of points with historic behavior of an Axiom A diffeomorphism has zero Lebesgue measure but, in some cases, it is a residual set. For example, it follows from Tak08 that this is the case of the well-known solenoid on the three-dimensional solid torus. Nevertheless, it is natural to ask the existence and abundance of diffeomorphisms whose set of initial points with historic behavior

[^0]has positive Lebesgue measure. Indeed, Takens' Last Problem Tak08 is whether there is a persistent class of dynamical systems such that the set of initial points with historic behavior has a positive Lebesgue measure. Here, we recall the concepts of persistence and robustness to avoid confusion. Let $\mathcal{C}$ be a non-empty subset of Diff ${ }^{r}(M)$, which is called a class. We say that a property $\mathscr{A}$ is $C^{r}$-persistent relative to $\mathcal{C}$ if every $f \in \mathcal{C}$ has the property $\mathscr{A}$. See PR83, Section 11] and Tak08, Section 3]. Such a property is called $C^{r}$-robust, particularly when $\mathcal{C}$ is an open set.

As an answer to Takens' Last Problem in dimension two, Kiriki and Soma [KS17] proved that the property of having a wandering domain with historic behavior is $C^{r}$ persistent relative to a dense subset of every Newhouse domain. This was extended in several directions LR17, Bar22, BB23. Here we go further and prove in Theorem A that there exist diffeomorphism $F_{0} \in \operatorname{Diff}^{r}(M)$ in a Newhouse domain and its $C^{r}$ neighborhood $\mathcal{U}_{0}$ all elements of which are strongly pluripotent for a Smale horseshoe. The concept of strong pluripotency, Definition 2.2, was borrowed from [KNS where it appeared for the first time. Roughly speaking, it implies that any orbit starting from Smale horseshoe for a diffeomorphism in $\mathcal{U}_{0}$, whose statistical behavior is arbitrarily prescribed in a combinatorial manner, can be realized by some nearby diffeomorphism and a set of points with positive Lebesgue measure.

As another result in Theorem B, we distinguish two dense classes with completely different statistical properties of $\mathcal{U}_{0}$. One is the class of diffeomorphisms which have a non-trivial physical measure supported on every orbit in a Smale horseshoe. The other is the class of diffeomorphisms $g$ which have a wandering domain $D$ such that, for every $x \in D$, the set of weak ${ }^{*}$ accumulation of the empirical measures $\delta_{x, g}^{n}$ contains at least two different measures supported on the Smale horseshoe.

## 2. BASIC CONCEPTS AND MAIN RESULTS

Throughout this paper, let $r$ be a fixed integer with $2 \leq r<\infty$ except the arguments on $C^{1+\alpha}$ topology in Section 2.4, $M$ a compact $C^{r}$ Riemannian surface without boundary and $\operatorname{Diff}^{r}(M)$ the set of all $C^{r}$ diffeomorphisms of $M$ endowed with the $C^{r}$ topology.
2.1. Wandering domain and pluripotency. Let us recall several topological concepts of dynamical systems. We say that $A \subset M$ is an attractor for $f \in$ Diff $^{r}(M)$, if $A$ is a compact $f$-invariant transitive set and its basin of attraction

$$
B_{f}(A)=\left\{x \in M: f^{n}(x) \rightarrow A \text { as } n \rightarrow+\infty\right\}
$$

contains a neighborhood of $A$. Moreover we say that $A$ is a weak attractor for $f$ if it satisfies the following conditions.

- $A$ is a non-wandering and dynamically connected invariant set (i.e. it is not the union of two non-trivial closed disjoint invariant sets),
- $B_{f}(A)$ contains an open set $C$ which has only finitely many connected components and such that the closure $c \ell(C)$ contains $A$.

Definition 2.1. A non-trivial wandering domain for $f \in \operatorname{Diff}^{r}(M)$ is a non-empty connected open set $D \subset M$ such that
(i) for any two integers $0 \leq i<j, f^{i}(D) \cap f^{j}(D)=\emptyset$,
(ii) $D$ is not contained in the basin of attraction of a weak attractor.

A wandering domain $D$ is called contracting if the diameter of $f^{n}(D)$ goes down to zero as $n$ goes to $+\infty$.

Note that the condition (ii) for non-triviality of the wandering domain in Definition 2.1 is stronger than the condition of dMvS93. In fact, for this stronger condition, a wandering domain of Denjoy's example on $S^{1}$ is no longer non-trivial since the basin of a weak attractor is the whole $S^{1}$. But the stronger condition is more effective than that of dMvS93 in eliminating several trivial examples of higher dimensions, e.g. Bowen eye or contracting saddle-node, see CV01.

Next, we recall the first Wasserstein metric $d_{W}$ for any Borel probability measures $\mu$ and $\nu$ on $M$ defined as

$$
d_{W}(\mu, \nu)=\sup _{\varphi \in \mathcal{L}}\left|\int_{M} \varphi d \mu-\int_{M} \varphi d \nu\right|,
$$

where $\mathcal{L}$ is the set of Lipschitz functions $\varphi: M \rightarrow[-1,1]$ with Lipschitz constants bounded by 1 . We now formulate the concepts of pluripotency and strong pluripotency which appeared for the first time in KNS.

Definition 2.2 (pluripotency). Let $\Lambda_{f}$ be a uniformly hyperbolic compact invariant set (for simplicity, hyperbolic set) for $f \in \operatorname{Diff}^{r}(M)$.

- $f$ is said to be pluripotent for $\Lambda_{f}$ if, for any $x \in \Lambda_{f}$, there exists $g \in$ Diff ${ }^{r}(M)$, arbitrarily $C^{r}$-close to $f$, which has a set of positive Lebesgue measure $D_{g}$ such that, for any $y \in D_{g}$,

$$
\lim _{n \rightarrow \infty} d_{W}\left(\delta_{y, g}^{n}, \delta_{x_{g}, g}^{n}\right)=0
$$

where $\delta_{y, g}^{n}$ and $\delta_{x_{g}, g}^{n}$ are empirical measures given as 1.1 and $x_{g} \in \Lambda_{g}$ is the continuation of $x \in \Lambda_{f}$.

- $f$ is said to be strongly pluripotent for $\Lambda_{f}$, if the above 2.1 is replaced by

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} \sup _{y \in D_{g}} \operatorname{dist}\left(g^{i}(y), g^{i}\left(x_{g}\right)\right)=0 \tag{2.2}
\end{equation*}
$$

Remark 2.3. We note something important about the above definition:
(1) In the results of this paper, the set corresponding to $D_{g}$ in Definition 2.2 is provided as a non-trivial wandering domain.
(2) It can be shown that (2.2) implies (2.1) while the converse is not true in general, see KNS.
(3) We can generalize Definition 2.2 to a subset of the hyperbolic invariant set rather than the entire hyperbolic invariant set. Compare Definition 2.2 with its generalized version in KNS.
2.2. Robust strongly pluripotency. The set of Axiom A diffeomorphisms without cycles is an open set. For such diffeomorphisms, the complement of their basins of attraction of their attractors has zero Lebesgue measure and the statistical behaviors of points in these basins are determined by SRB measures. Therefore, these diffeomorphisms are not pluripotent for any basic set. On the other hand, we prove the existence of an open set of strongly pluripotent diffeomorphisms $f$ for a wild Smale horseshoe: a uniformly hyperbolic invariant set $\Lambda$ such that the restriction $\left.f\right|_{\Lambda}$ is topologically conjugated to the shift map on the full two-sided two-shift space and besides which has a homoclinic tangency. Note that the property of having a homoclinic tangency is $C^{r}$-persistent relative to an open set, namely $C^{r}$ robust, in Diff ${ }^{r}(M)$. Such an open set is called a Newhouse domain. Newhouse
domains are shown to be non-empty by Newhouse for 2-dimensional $C^{2}$ diffeomorphisms New79, by Crovisier et al. for 2-dimensional $C^{1+\alpha}$ diffeomorphisms Cro (see Section 2.4 below), and by Bonatti-Díaz for three or higher dimensional $C^{r}$ diffeomorphisms BD96]. See [PT93, BDV05] for a comprehensive explanation.

The starting point for pluripotency is based on ideas used in CV01 to prove the existence of wandering domains with different ergodic properties. These ideas were also adopted in [KS17] to give an affirmative solution to Takens' Last Problem in two-dimensional diffeomorphisms. In KNS23, similar ideas were extended to three-dimensional diffeomorphisms with a wild blender-horseshoe and we studied statistical dynamics of the contracting wandering domain. In KNS, the pluripotency and strong pluripotency are formulated for the first time and these properties are shown to be $C^{2}$-robust for a diffeomorphism with a wild blender-horseshoe. Note, however, that the pluripotency studied in [KNS is limited to some proper subsets of blender-horseshoe. In other words, it remains unknown whether there exists an open set of strongly pluripotent diffeomorphisms for the whole part of a basic set such as a horseshoe even in two-dimension. To this problem, we give the next result for two-dimensional diffeomorphisms.
Theorem A. There is an $F_{0} \in \operatorname{Diff}^{r}(M)$ having a wild Smale horseshoe $\Lambda_{F_{0}}$ and a $C^{r}$ neighborhood $\mathcal{U}_{0}$ of $F_{0}$ such that every diffeomorphism $f \in \mathcal{U}_{0}$ is strongly pluripotent for the continuation $\Lambda_{f}$ of $\Lambda_{F_{0}}$.

The positive Lebesgue measure set in the proof of Theorem A corresponding to $D_{g}$ in Definition 2.2 is given as a non-trivial wandering domain for some $g$ arbitrarily $C^{r}$ close to $f$. See the subsequent sections for details. Note that, by the result in [KS17, we might obtain a similar conclusion in some open sets in $\mathcal{U}_{0}$ close to $F_{0}$, but there is no guarantee in such a way that the conclusion is correct in the whole $\mathcal{U}_{0}$.
2.3. Persistent properties in $\mathcal{U}_{0}$. Next, we state that any strongly pluripotent diffeomorphism in $\mathcal{U}_{0}$ can be approximated by two classes with completely different statistical properties defined as follows.

The first property is the existence of non-trivial physical measure $\mu$ satisfying the following conditions:

- for $g \in \mathcal{U}_{0}$, there exists $x \in M$ such that $\left(\delta_{x, g}^{n}\right)_{n \geq 0}$ converges to an invariant Borel measure $\mu$ whose support $\operatorname{supp}(\mu)$ is not an attractor,
- the basin $B_{g}(\mu)=\left\{x \in M: \delta_{x, g}^{n} \xrightarrow{\text { weak* }} \mu\right.$ as $\left.n \rightarrow \infty\right\}$ of $\mu$ has positive Lebesgue measure.
Moreover, we say that a non-trivial physical measure $\mu$ is Dirac if the support of $\mu$ is a periodic orbit of saddle type. We call a point $x$ Birkhoff regular for $g$ if $\left(\delta_{x, g}^{n}\right)_{n \geq 0}$ converges to an invariant Borel measure. For a Birkhoff regular point $q \in \Lambda_{F_{0}}$, we say that $g \in \mathcal{U}_{0}$ satisfies the property $\mathscr{D}_{q}$ if $g$ has a non-trivial physical measure whose support is the closure of the orbit of the continuation $q_{g}$ of $q$.

The second one is the existence of historic behavior which already appeared in the previous section:

- for $g \in \mathcal{U}_{0}$ there exists $x \in M$ such that the sequence $\left(\delta_{x, g}^{n}\right)_{n \geq 0}$ of empirical measures given as (1.1) does not converge.
We say that $g \in \mathcal{U}_{0}$ satisfies the property $\mathscr{H}$ if $g$ has a non-trivial wandering domain such that the $g$-forward orbit of each point in the domain has historic behavior.

Theorem B. Suppose that $\mathcal{U}_{0}$ is the $C^{r}$ neighborhood of $F_{0}$ in Theorem A. Then there exist a dense class $\mathcal{H}$ of $\mathcal{U}_{0}$ and, for any Birkhoff regular point $q \in \Lambda_{F_{0}}$, another dense class $\mathcal{D}_{q}$ of $\mathcal{U}_{0}$ satisfying the following conditions.
(1) $\mathscr{D}_{q}$ is $C^{r}$-persistent relative to $\mathcal{D}_{q}$.
(2) $\mathscr{H}$ is $C^{r}$-persistent relative to $\mathcal{H}$.

Remark 2.4. The result of Theorem B (2) is an affirmative answer to Takens' Last Problem which could not be obtained from that of KS17. Indeed, though the result of [KS17] provides a locally dense subset of an open set arbitrarily close to $F_{0}$, it does not guarantee that it is dense in a neighborhood of $F_{0}$
2.4. The $C^{1+\alpha}$ case. Theorems A and B would also hold for every real number $r=1+\alpha$ with $0<\alpha<1$. It is well-known that homoclinic tangencies for two-dimensional diffeomorphisms exist $C^{r}$-robustly if $r \geq 2$ (New79] but does not if $r=1$ [Mor11]. On the other hand, it was not publicly known whether 2-dimensional diffeomorphisms have $C^{r}$-robust homoclinic tangency when $1<r<2$. But two years later after Mor11, Crovisier and Gourmelon gave a positive answer to the problem and recently provided it in the lecture note [Cro, Remark 1]. The most important part of their proof is that it presents a new way to evaluate overlappings of stable and unstable laminations of a horseshoe of a $C^{1+\alpha}$ diffeomorphism in a way different from the conventional method for $r \geq 2$. One of the ingredients they provided in CrO is the existence of Lipschitz holonomy along the local unstable and stable laminations, see also [BCS22, Appendix A]. Using this, they also provided the following lemma, where the definition of thickness is rather technical and will be given in the next section.

Lemma 2.5 (Continuity of thickness Cro, §4 Proposition 2]). Let $\alpha$ be a real number with $0<\alpha<1$ and $f$ a $C^{1+\alpha}$ diffeomorphism having a horseshoe $\Lambda$ on $a$ closed surface $M$. The stable thickness $\tau^{\mathrm{s}}\left(\Lambda_{g}\right)$ of the continuation $\Lambda_{g}$ of $\Lambda$ depends continuously on $g$ in a $C^{1}$ neighborhood of $f$ on the space of $C^{1+\alpha}$ diffeomorphisms such that the $\alpha$-Hölder norm of $D g, D g^{-1}$ is bounded by $C>0$.

Note that, since the unstable thickness $\tau^{\mathrm{u}}\left(\Lambda_{g}\right)$ is equal to $\tau^{\mathrm{s}}\left(\Lambda_{g^{-1}}\right)$, the same result holds for the unstable thickness. In $C^{r}$ topology with $r \geq 2$, the continuity of thickness is shown in New79, PT93.
Remark 2.6 (Continuity of denseness). A slight modification of the definition of thickness yields the concept of denseness, see Definition 3.1. It is therefore easy to see from the proof of Cro, §4 Proposition 2] that the claim of Lemma 2.5 with thickness replaced by denseness is still true. The denseness will be used in Section 7.
2.5. Open problem and outline. For future developments, we compare KS17, Theorem A] with our Theorem A. The former theorem states that the set $\mathcal{H}$ is dense in any Newhouse open set in $\operatorname{Diff}^{r}(M)$ but it does not discuss the property of strong pluripotency. On the other hand, our Theorem A guarantees that a Newhouse open set in $\operatorname{Diff}^{r}(M)$ contains the open proper subset $\mathcal{U}_{0}$ of strongly pluripotent diffeomorphisms. In particular, it follows that $\mathcal{H}$ and $\mathcal{D}_{q}$ are both dense in $\mathcal{U}_{0}$. Thus, the following problem remains open.
Problem 2.7. Is any diffeomorphism belonging to every Newhouse domain strongly pluripotent?

This paper is organized as follows: in Section 3. we introduce several definitions including a model of a wild Smale horseshoe and its $C^{r}$ neighborhood. In Section 4 , we provide some necessary notions and properties about the structures of Cantor sets. Sections 5 to 8 are devoted to developing four lemmas which will be used in the proof of Theorem A. Finally, Theorem B is proved in Section 9 .

## 3. Robust wild horseshoes

3.1. The Colli-Vargas model $F$. To obtain $F_{0}$ in Theorem A, we consider the socalled Colli-Vargas model. Let $F$ be a $C^{r}$ diffeomorphism having a wild horseshoe on a closed surface $M$ and identical to the one given in CV01. More precisely, it is defined as follows. We may suppose that $M$ has a local chart defined on an open set which is identified with an open set containing $(-2,2)^{2}$ of $\mathbb{R}^{2}$. In this open set, we consider the rectangle $Q=[-1,1]^{2}$ and the disjoint vertical strips of $Q$ defined as

$$
S_{0}=\left[-\frac{1}{2}-\sigma^{-1},-\frac{1}{2}+\sigma^{-1}\right] \times[-1,1], \quad S_{1}=\left[\frac{1}{2}-\sigma^{-1}, \frac{1}{2}+\sigma^{-1}\right] \times[-1,1]
$$

for some constant $\sigma>2$. We assume that $\left.F\right|_{S_{0} \cup S_{1}}$ satisfies

$$
F(x, y)= \begin{cases}\left(\sigma\left(x+\frac{1}{2}\right),-\frac{1}{2}+\lambda y\right) & \text { if }(x, y) \in S_{0} \\ \left(-\sigma\left(x-\frac{1}{2}\right), \frac{1}{2}-\lambda y\right) & \text { if }(x, y) \in S_{1}\end{cases}
$$

for some $\lambda>0$ with

$$
\begin{equation*}
\lambda \sigma<1 \tag{3.1}
\end{equation*}
$$

It follows immediately from $\sigma>2$ that we actually have $\lambda<\sigma^{-1}<1 / 2$. Thus, there is an affine horseshoe for $F$ as

$$
\begin{equation*}
\Lambda=\Lambda_{F}=\bigcap_{n \in \mathbb{Z}} F^{n}\left(S_{0} \cup S_{1}\right) \tag{3.2}
\end{equation*}
$$

Then $\left.F\right|_{\Lambda}$ is topologically conjugate to the full two-sided shift on two symbols by the homeomorphism $h=h_{F}: \Lambda_{F} \rightarrow\{0,1\}^{\mathbb{Z}}$ given by

$$
(h(x))_{j}=w \quad \text { if } \quad F^{j}(x) \in S_{w}
$$

where $(h(x))_{j}$ is the $j$ th entry of $h(x)$. Let the fixed point $h_{F}^{-1}(\underline{0})$ of $F$ with $\underline{0}=(\ldots 000 \ldots)$ be denoted by $p=p_{F}$, and hence it satisfies $p=\left(-a_{\mathrm{u}},-a_{\mathrm{s}}\right)$, where $a_{\mathrm{u}}=\left(2\left(1-\sigma^{-1}\right)\right)^{-1}$ and $a_{\mathrm{s}}=(2(1-\lambda))^{-1}$.

Next we consider any $f$ which is $C^{r}$-close to $F$. The intersection $Q \cap f^{-1}(Q)$ consists of two disjoint components, denoted by $S_{0, f}$ and $S_{1, f}$, such that

$$
\lim _{f \rightarrow F} S_{i, f}=S_{i}
$$

for each $i \in\{0,1\}$. See Figure 3.1. Then we have the hyperbolic continuation $\Lambda_{f}=$ $\bigcap_{n \in \mathbb{Z}} f^{n}\left(S_{0, f} \cup S_{1, f}\right)$ of $\Lambda_{F}$. Let us denote by $W_{\text {loc }}^{\mathrm{u}}\left(\Lambda_{f}\right)$ the union of local unstable manifolds $W_{\text {loc }}^{\mathrm{u}}(x)$ in $Q$ with $x \in \Lambda_{f}$. We write $B_{0, f}=f\left(S_{0, f}\right), B_{1, f}=f\left(S_{1, f}\right)$ and denote by $G_{0, f}$ the component of $Q \backslash W_{\text {loc }}^{\mathrm{u}}\left(\Lambda_{f}\right)$ between $B_{0, f}$ and $B_{1, f}$. Then, for any component $G_{f}$ of $Q \backslash W_{\mathrm{loc}}^{\mathrm{u}}\left(\Lambda_{f}\right)$ contained in $B_{0, f} \cup B_{1, f}$, there exists an integer $n \geq 1$ such that $f^{-n}\left(G_{f}\right) \subset G_{0, f}$. For such a $G_{f}$ we have two rectangles $B_{f}^{+}$and
$B_{f}^{-}$which are the connected components of $f^{n}\left(B_{0, f}\right) \cap Q$ and $f^{n}\left(B_{1, f}\right) \cap Q$ adjacent to $G_{f}$.

Figure 3.1.

Definition 3.1. Let $x$ be a point of $\Lambda_{f}$ and $\ell$ a connected component of $W_{\text {loc }}^{\mathrm{s}}(x) \backslash \Lambda_{f}$ contained in $G_{f}$.

- The stable thickness of $\Lambda_{f}$ at $\ell$ is

$$
\begin{equation*}
\tau\left(\Lambda_{f}, \ell\right)=\frac{\min \left\{\left|B_{f}^{-} \cap W_{\mathrm{loc}}^{\mathrm{s}}(x)\right|,\left|B_{f}^{+} \cap W_{\mathrm{loc}}^{\mathrm{s}}(x)\right|\right\}}{|\ell|} \tag{3.3}
\end{equation*}
$$

where $|\cdot|$ stands for the arc-length of the corresponding arc. Moreover the stable thickness of $\Lambda_{f}$ is defined by

$$
\tau^{\mathrm{s}}\left(\Lambda_{f}\right)=\inf _{\ell} \tau\left(\Lambda_{f}, \ell\right)
$$

where the infimum is taken over all connected components $\ell$ of $W_{\text {loc }}^{\mathrm{s}}(x) \backslash \Lambda_{f}$ contained in $B_{0, f} \cup G_{0, f} \cup B_{1, f}$.

- The unstable thickness $\tau^{\mathrm{u}}\left(\Lambda_{f}\right)$ of $\Lambda_{f}$ is defined as the stable thickness with respect to $f^{-1}$.
- The constant obtained by replacing 'min' with 'max' in (3.3) is called the stable denseness of $\Lambda_{f}$ at $\ell$ and denoted by $\theta\left(\Lambda_{f}, \ell\right)$. Moreover, the constant obtained by replacing 'inf' with 'sup' and ' $\tau$ ' with ' $\theta$ ' in (3.4) is called the stable denseness of $\Lambda_{f}$ and denoted by $\theta^{\mathrm{s}}\left(\Lambda_{f}\right)$.
- The unstable denseness $\theta^{\mathrm{u}}\left(\Lambda_{f}\right)$ of $\Lambda_{f}$ is defined as the stable denseness with respect to $f^{-1}$.
Since the horseshoe $\Lambda$ given in (3.2) is affine, we have

$$
\begin{equation*}
\tau^{\mathrm{s}}(\Lambda)=\theta^{\mathrm{s}}(\Lambda)=\frac{\lambda}{1-2 \lambda}=: \tau^{\mathrm{s}}, \quad \tau^{\mathrm{u}}(\Lambda)=\theta^{\mathrm{u}}(\Lambda)=\frac{\sigma^{-1}}{1-2 \sigma^{-1}}=: \tau^{\mathrm{u}} \tag{3.5}
\end{equation*}
$$

We consider the case that $\lambda$ and $\sigma$ satisfy the open condition

$$
\begin{equation*}
\tau^{\mathrm{s}} \tau^{\mathrm{u}}>1 \tag{3.6}
\end{equation*}
$$

which ensures that $C^{r}$-robust homoclinic tangencies occur by (3.9) below. Moreover, it follows from (3.1) that $\lambda<\sigma^{-1}$, thus we have

$$
\tau^{\mathrm{s}}=\frac{\lambda}{1-2 \lambda}<\frac{\sigma^{-1}}{1-2 \sigma^{-1}}=\tau^{\mathrm{u}}
$$

which implies, according to (3.6), that

$$
\begin{equation*}
\frac{\sigma^{-1}}{1-2 \sigma^{-1}}=\tau^{\mathrm{u}}>1 \tag{3.7}
\end{equation*}
$$

As a result, the constant $\sigma$ actually satisfies

$$
\begin{equation*}
2<\sigma<3 \tag{3.8}
\end{equation*}
$$

In such a situation, we assume that, for any $(x, y)$ in a small neighborhood $U$ of $\left(0,-a_{\mathrm{s}}\right)$ in $(-2,2)^{2}$,

$$
\begin{equation*}
F^{2}(x, y)=\left(-a_{\mathrm{u}}+\mu-\beta x^{2}+\gamma\left(y+a_{\mathrm{s}}\right),-\alpha x\right), \tag{3.9}
\end{equation*}
$$

where $\mu$ is positive and will be adjusted later as we need, and $\alpha, \beta, \gamma$ are positive constants. Then 3.9 preserves the orientation. This completes $F$ 's setup.
3.2. A small $C^{r}$ neighborhood $\mathcal{U}_{F}^{r}$ of $F$. Now, we are ready to consider a $C^{r}$ neighborhood of $F$ in $\operatorname{Diff}^{r}(M)$. For a small $\varepsilon_{0}>0$, we write

$$
\begin{equation*}
\underline{\lambda}=\lambda-\varepsilon_{0}, \bar{\lambda}=\lambda+\varepsilon_{0}, \underline{\sigma}=\sigma-\varepsilon_{0}, \bar{\sigma}=\sigma+\varepsilon_{0} . \tag{3.10}
\end{equation*}
$$

According to (3.1) and (3.8), we may suppose that

$$
\begin{equation*}
2<\bar{\sigma}<3 \quad \text { and } \quad \bar{\lambda} \bar{\sigma}<1 \tag{3.11}
\end{equation*}
$$

by shrinking $\varepsilon_{0}$ if necessary.
Let $\pi_{x}$ and $\pi_{y}$ be the orthogonal projection to the $x$ and $y$-axes, respectively. We now consider a $C^{r}$-neighborhood $\mathcal{U}_{F}^{r}$ of $F$ in $\operatorname{Diff}^{r}(M)$ depending on $\varepsilon_{0}$ and satisfying the following conditions:

$$
\begin{aligned}
& \sup \left\{\left\|D\left(\pi_{y} \circ f\right)(x)\right\|: f \in \mathcal{U}_{F}^{r}, x \in S_{0, f} \cup S_{1, f}\right\}<\bar{\lambda}-\frac{\varepsilon_{0}}{2} \\
& \inf \left\{m\left(D\left(\pi_{y} \circ f\right)(x)\right): f \in \mathcal{U}_{F}^{r}, x \in S_{0, f} \cup S_{1, f}\right\}>\underline{\lambda}+\frac{\varepsilon_{0}}{2} \\
& \sup \left\{\left\|D\left(\pi_{x} \circ f\right)(x)\right\|: f \in \mathcal{U}_{F}^{r}, x \in S_{0, f} \cup S_{1, f}\right\}<\bar{\sigma}-\frac{\varepsilon_{0}}{2} \\
& \inf \left\{m\left(D\left(\pi_{x} \circ f\right)(x)\right): f \in \mathcal{U}_{F}^{r}, x \in S_{0, f} \cup S_{1, f}\right\}>\underline{\sigma}+\frac{\varepsilon_{0}}{2},
\end{aligned}
$$

where $\|\cdot\|$ and $m(\cdot)$ stand for the operator and minimum norms, respectively, of a given linear map. Then we may suppose that each $f \in \mathcal{U}_{F}^{r}$ has the horseshoe $\Lambda_{f}$ which is the continuation of $\Lambda$. Since $(3.6)$ holds for $F$, by shrinking $\mathcal{U}_{F}^{r}$ if necessary, we can suppose that

$$
\begin{equation*}
\tau^{\mathrm{s}}\left(\Lambda_{f}\right) \tau^{\mathrm{u}}\left(\Lambda_{f}\right)>1 \tag{3.12}
\end{equation*}
$$

holds for every $f$ in $\mathcal{U}_{F}^{r}$. This is because the stable thickness $\tau^{\mathrm{s}}\left(\Lambda_{f}\right)$ and the unstable thickness $\tau^{\mathrm{u}}\left(\Lambda_{f}\right)$ vary continuously on $f$. Similarly, note that the stable and unstable denseness also vary continuously on $f$, see Remark 2.6. Combining this fact with (3.5), we know that the stable and unstable denseness of $\Lambda$ are positive. So there exists $\theta=\theta\left(\mathcal{U}_{F}^{r}\right)>0$ such that

$$
\begin{equation*}
\max \left\{\sup _{f \in \mathcal{U}_{F}^{r}} \theta^{\mathrm{s}}\left(\Lambda_{f}\right), \sup _{f \in \mathcal{U}_{F}^{r}} \theta^{\mathrm{u}}\left(\Lambda_{f}\right)\right\}<\theta \tag{3.13}
\end{equation*}
$$

Moreover, $\left.f^{2}\right|_{U}$ is given by an expression close to (3.9) as follows

$$
\begin{equation*}
f^{2}(x, y)=\left(-\bar{a}_{\mathrm{u}}+\bar{\mu}-\bar{\beta} x^{2}+\bar{\gamma}\left(y+\bar{a}_{\mathrm{s}}\right),-\bar{\alpha} x\right)+h(x, y) \tag{3.14}
\end{equation*}
$$

where each coefficient is close to that in 3.9 and $h(x, y)$ stands for the higher order terms containing $o\left(x^{2}\right)$ and $o(y)$.

Let $\mathcal{F}^{\mathrm{s}}$ and $\mathcal{F}^{\mathrm{u}}$ be local stable and unstable foliations for $\Lambda_{f}$ defined on $S_{0, f} \cup S_{1, f}$ and $f\left(S_{0, f} \cup S_{1, f}\right)$, respectively. These foliations certainly depend on $f$. Hence we also write $\mathcal{F}_{f}^{\mathrm{s}}$ and $\mathcal{F}_{f}^{\mathrm{u}}$ if the dependence need to be emphasized. Then, shrinking $\mathcal{U}_{F}^{r}$ agian if necessary, by (3.6) and (3.14) we may assume that the intersection between leaves of $\mathcal{F}^{\mathrm{s}}$ and those of $f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)$ contains the $C^{1}$ arc of homoclinic quadratic tangencies of $\Lambda_{f}$, denoted by $L$. See PT93. We call it a tangency curve for simplicity. On the other hand, the $f^{-2}$-image of $L$ is denoted by $\widetilde{L}$, see Figure 3.2 . We point out that both $L$ and $\widetilde{L}$ depend on $f$ as well.

Figure 3.2.

When the parameter $\bar{\mu}>0$ is fixed first and next it is slid by $\delta$ from $\bar{\mu}$, that is, we define the $\delta$-slid perturbation $f_{\delta}$ of $f$ on $f(U)$ by letting

$$
\begin{aligned}
f_{\delta}^{2}(x, y): & =f^{2}(x, y)+(\delta, 0) \\
& =\left(-\bar{a}_{\mathrm{u}}+\bar{\mu}+\delta-\bar{\beta} x^{2}+\bar{\gamma}\left(y+\bar{a}_{\mathrm{s}}\right),-\bar{\alpha} x\right)+h(x, y)
\end{aligned}
$$

Since $f_{\delta}^{2}\left(\mathcal{F}^{\mathrm{u}}\right)$ is slid by $\delta$ along the horizontal direction, we have the new $C^{1}$ arc of homoclinic tangencies between $f_{\delta}^{2}\left(\mathcal{F}^{\mathrm{u}}\right)$ and $\mathcal{F}^{\mathrm{s}}$, which is denoted by $L(\delta)$. Moreover, we denote $f_{\delta}^{-2}(L(\delta))$ by $\widetilde{L}(\delta)$. It follows immediately that

$$
\lim _{\delta \rightarrow 0} L(\delta)=L \quad \text { and } \quad \lim _{\delta \rightarrow 0} \widetilde{L}(\delta)=\widetilde{L}
$$

## 4. BRIDGES, GAPS AND BOUNDED DISTORTION

4.1. Bridges and gaps. Let $f$ be any diffeomorphism in $\mathcal{U}_{F}^{r}$ with the wild Smale horseshoe $\Lambda_{f}$. The continuation of the saddle fixed point $p_{F}$ is denoted by $p_{f}$ and the connected components $W^{\mathrm{s}}\left(p_{f}\right) \cap Q$ and $W^{\mathrm{u}}\left(p_{f}\right) \cap Q$ containing $p_{f}$ is denoted by $I^{\mathrm{s}}$ and $I^{\mathrm{u}}$, respectively. See Figure 3.2 . Sometimes we also write $I_{f}^{\mathrm{s}}$ and $I_{f}^{\mathrm{u}}$ if their dependence on $f$ needs to be emphasized. Then we have two Cantor sets

$$
\begin{equation*}
\Lambda_{f}^{\mathrm{s}}=\Lambda_{f} \cap I^{\mathrm{s}} \quad \text { and } \quad \Lambda_{f}^{\mathrm{u}}=\Lambda_{f} \cap I^{\mathrm{u}} \tag{4.1}
\end{equation*}
$$

For these two Cantor sets, in a similar way as that in Definition 3.1, one can also define their thicknesses $\tau\left(\Lambda_{f}^{\mathrm{s}}\right)$ and $\tau\left(\Lambda_{f}^{\mathrm{u}}\right)$. One can deduce that

$$
\tau\left(\Lambda_{f}^{\mathrm{s}}\right)=\tau^{\mathrm{s}}\left(\Lambda_{f}\right) \quad \text { and } \quad \tau\left(\Lambda_{f}^{\mathrm{u}}\right)=\tau^{\mathrm{u}}\left(\Lambda_{f}\right)
$$

The notion of thickness plays an important role when we are aiming to find the intersection of two given Cantor sets. Precisely, the following so-called Gap Lemma is quite helpful.

Lemma 4.1 (Gap Lemma New79, PT93). Let $K_{1}, K_{2}$ be Cantor sets with thicknesses $\tau_{1}$ and $\tau_{2}$. If $\tau_{1} \tau_{2}>1$, then one of the following three alternatives occurs: $K_{1}$ is contained in a gap of $K_{2} ; K_{2}$ is contained in a gap of $K_{1} ; K_{1} \cap K_{2} \neq \emptyset$.

We now introduce bridges and gaps related to $\Lambda_{f}^{\mathrm{s}}$ and $\Lambda_{f}^{\mathrm{u}}$. For each $i \in\{-1,0,1\}$, let $I_{i}^{\mathrm{s}}$ and $I_{i}^{\mathrm{u}}$ be the component of $I^{\mathrm{s}} \backslash \Lambda_{f}^{\mathrm{s}}$ and $I^{\mathrm{u}} \backslash \Lambda_{f}^{\mathrm{u}}$ such that $I_{i}^{\mathrm{s}} \cap\{y=i\} \neq \emptyset$ and $I_{i}^{\mathrm{u}} \cap\{x=i\} \neq \emptyset$. Let $\left(B r^{\mathrm{s}}(0), B r^{\mathrm{s}}(1)\right)$ be the pair of components of $I^{\mathrm{s}} \backslash\left(I_{-1}^{\mathrm{s}} \cup I_{0}^{\mathrm{s}} \cup I_{1}^{\mathrm{s}}\right)$ and $\left(B r^{\mathrm{u}}(0), B r^{\mathrm{u}}(1)\right)$ the pair of components of $I^{\mathrm{u}} \backslash\left(I_{-1}^{\mathrm{u}} \cup I_{0}^{\mathrm{u}} \cup I_{1}^{\mathrm{u}}\right)$ such that

$$
\pi_{y}\left(B r^{\mathrm{s}}(0)\right)<0<\pi_{y}\left(B r^{\mathrm{s}}(1)\right), \quad \pi_{x}\left(B r^{\mathrm{u}}(0)\right)<0<\pi_{x}\left(B r^{\mathrm{u}}(1)\right)
$$

Next, we consider other projections

$$
\begin{equation*}
\pi_{\mathcal{F}^{\mathrm{s}}}: S_{0, f} \cup S_{1, f} \rightarrow I^{\mathrm{u}}, \quad \pi_{\mathcal{F}^{\mathrm{u}}}: f\left(S_{0, f} \cup S_{1, f}\right) \rightarrow I^{\mathrm{s}}, \tag{4.2}
\end{equation*}
$$

where the former is along the leaves of $\mathcal{F}^{\mathrm{s}}$ and the latter is along the leaves of $\mathcal{F}^{\mathrm{u}}$. Since both $\mathcal{F}^{\mathrm{s}}$ and $\mathcal{F}^{\mathrm{u}}$ are $C^{1}$-foliations and every leaf of them transversely meets $I^{\mathrm{u}}$ and $I^{\mathrm{s}}$, respectively, $\pi_{\mathcal{F}^{\mathrm{s}}}$ and $\pi_{\mathcal{F}^{\mathrm{u}}}$ are $C^{1}$-submersions. Then we have two pairs of horizontal strips and vertical strips in $Q$ defined as

$$
\begin{aligned}
& \mathbb{B} r^{\mathrm{s}}(0)=\left(\pi_{\mathcal{F}^{\mathrm{u}}}\right)^{-1}\left(B r^{\mathrm{s}}(0)\right), \quad \mathbb{B} r^{\mathrm{s}}(1)=\left(\pi_{\mathcal{F}^{\mathrm{u}}}\right)^{-1}\left(B r^{\mathrm{s}}(1)\right) \\
& \mathbb{B} r^{\mathrm{u}}(0)=\left(\pi_{\mathcal{F}^{\mathrm{s}}}\right)^{-1}\left(B r^{\mathrm{u}}(0)\right), \quad \mathbb{B} r^{\mathrm{u}}(1)=\left(\pi_{\mathcal{F}^{\mathrm{s}}}\right)^{-1}\left(B r^{\mathrm{u}}(1)\right)
\end{aligned}
$$

Note that $\mathbb{B} r^{s}(w) \subset f\left(S_{w, f}\right)$ and $\mathbb{B} r^{u}(w) \subset S_{w, f}$ for each $w \in\{0,1\}$. See Figure 3.2 .

For every integer $n \geq 1$, let $\underline{w}$ be a binary code of $n$ entries, that is, $\underline{w}=$ $\left(w_{1} \ldots w_{n}\right) \in\{0,1\}^{n}$. For such $n$ and $w_{n}$, we define

$$
\begin{aligned}
& \mathbb{B} r^{\mathrm{s}}(n ; \underline{w})=\left\{x \in Q: f^{-i+1}(x) \in \mathbb{B} r^{\mathrm{s}}\left(w_{i}\right), i=1, \ldots, n\right\}, \\
& \mathbb{B} r^{\mathrm{u}}(n ; \underline{w})=\left\{x \in Q: f^{i-1}(x) \in \mathbb{B} r^{\mathrm{u}}\left(w_{i}\right), i=1, \ldots, n\right\}
\end{aligned}
$$

and hence $\mathbb{B} r^{\mathrm{s}}(1 ; w)=\mathbb{B} r^{\mathrm{s}}(w)$ and $\mathbb{B} r^{\mathrm{u}}(1 ; w)=\mathbb{B} r^{\mathrm{u}}(w)$ for each $w \in\{0,1\}$. Given $n \in \mathbb{N}$ and $\underline{w} \in\{0,1\}^{n}$, we call $\mathbb{B} r^{\mathrm{s}}(n ; \underline{w})$ the s-bridge strip and $\mathbb{B} r^{\mathrm{u}}(n ; \underline{w})$ the $u$ bridge strip. See Figure 4.1 . Observe that, for each integer $n \geq 1,\left(\mathbb{B} r^{s}(n ; \underline{w})\right)_{\underline{w} \in\{0,1\}^{n}}$ and $\left(\mathbb{B} r^{u}(n ; \underline{w})\right)_{\underline{w} \in\{0,1\}^{n}}$ consist of $2^{n}$ mutually disjoint horizontal and vertical strips, respectively. It is easy to verify that

$$
f^{n}\left(\mathbb{B} r^{\mathrm{u}}\left(n ; w_{1} \ldots w_{n}\right)\right)=\mathbb{B} r^{\mathrm{s}}\left(n ; w_{n} \ldots w_{1}\right)=\mathbb{B} r^{\mathrm{s}}\left(n ;\left[w_{1} \ldots w_{n}\right]^{-1}\right)
$$

Moreover, we set

$$
\begin{align*}
& B r^{\mathrm{s}}(n ; \underline{w})=\mathbb{B} r^{\mathrm{s}}(n ; \underline{w}) \cap I^{\mathrm{s}}=\pi_{\mathcal{F}^{\mathrm{u}}}\left(\mathbb{B} r^{\mathrm{s}}(n ; \underline{w})\right) \\
& B r^{\mathrm{u}}(n ; \underline{w})=\mathbb{B}^{\mathrm{u}}(n ; \underline{w}) \cap I^{\mathrm{u}}=\pi_{\mathcal{F}^{\mathrm{s}}}\left(\mathbb{B} r^{\mathrm{u}}(n ; \underline{w})\right) \tag{4.3}
\end{align*}
$$

which are called s-bridge of $\Lambda_{f}^{\mathrm{s}}$ and u-bridge of $\Lambda_{f}^{\mathrm{u}}$, respectively. In these notations, $n$ is called the generation and $\underline{w}$ the itinerary for the corresponding bridges and bridge strips. The length of $\underline{w}$, denoted by $|\underline{w}|$, is defined as the cardinality of binary codes that comprise $\underline{w}$, that is, $|\underline{w}|=\left|\left(w_{1} \ldots w_{n}\right)\right|=n$.

Figure 4.1. The notation $(n ; \underline{w})$ of each bridge and strip is omitted.

Next, the maximum subinterval of $B r^{\mathrm{s}}(n ; \underline{w})$ between $B r^{\mathrm{s}}(n+1 ; \underline{w} 0)$ and $B r^{\mathrm{s}}(n+$ $1 ; \underline{w} 1)$ is denoted by $G a^{\mathrm{s}}(n ; \underline{w})$, while the maximum subinterval of $B r^{\mathrm{u}}(n ; \underline{w})$ between $B r^{\mathrm{u}}(n+1 ; \underline{w} 0)$ and $B r^{\mathrm{u}}(n+1 ; \underline{w} 1)$ is denoted by $G a^{\mathrm{u}}(n ; \underline{w})$, which are respectively called the s-gap and u-gap of generation $n$ and itinerary $\underline{w}$. The two bridges $B r^{\mathrm{s}(\mathrm{u})}(n+1 ; \underline{w} 0)$ and $B r^{\mathrm{s}(\mathrm{u})}(n+1 ; \underline{w} 1)$ are called adjacent $\mathrm{s}(\mathrm{u})$-bridges of $G a^{\mathrm{s}(\mathrm{u})}(n ; \underline{w})$. If it is necessary to specify the diffeomorphism $f$ concerning the $\mathrm{s}(\mathrm{u})$-bridge and gap, we may write $B r_{f}^{\mathrm{s}(\mathrm{u})}(n ; \underline{w})$ and $G a_{f}^{\mathrm{s}(\mathrm{u})}(n ; \underline{w})$.

To introduce the $\mathrm{s}(\mathrm{u})$-bridges and $\mathrm{s}(\mathrm{u})$-gaps on the tangency curves $L$ and $\widetilde{L}$, we consider extended projections

$$
\pi_{f^{-2}\left(\mathcal{F}^{\mathrm{s}}\right)}: f^{-2}\left(S_{0, f} \cup S_{1, f}\right) \rightarrow I^{\mathrm{u}}, \quad \pi_{f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)}: f^{2}\left(f\left(S_{0, f} \cup S_{1, f}\right)\right) \rightarrow I^{\mathrm{s}}
$$

where the former is the projection along the leaves of $f^{-2}\left(\mathcal{F}^{\mathrm{s}}\right)$ and the latter is that along the leaves of $f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)$. Let $B^{\mathrm{s}}(n ; \underline{w})$ and $B^{\mathrm{u}}(n ; \underline{w})$ be the sub-arcs of $L$ with the following conditions:

$$
\begin{equation*}
B r^{\mathrm{s}}(n ; \underline{w})=\pi_{f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)}\left(B^{\mathrm{s}}(n ; \underline{w})\right), \quad B r^{\mathrm{u}}(n ; \underline{w})=\pi_{\mathcal{F}^{\mathrm{s}}}\left(B^{\mathrm{u}}(n ; \underline{w})\right), \tag{4.4}
\end{equation*}
$$

which are called s and u-bridges on $L$, respectively. Moreover, in the same manner, the two Cantor sets $\Lambda_{f}^{\mathrm{s}}$ and $\Lambda_{f}^{\mathrm{u}}$ defined in 4.1) also have their projections $\Lambda_{L}^{\mathrm{s}}$ and $\Lambda_{L}^{\mathrm{u}}$ on $L$ defined by

$$
\begin{equation*}
\Lambda_{f}^{\mathrm{s}}=\pi_{f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)}\left(\Lambda_{L}^{\mathrm{s}}\right) \quad \text { and } \quad \Lambda_{f}^{\mathrm{u}}=\pi_{\mathcal{F}^{\mathrm{s}}}\left(\Lambda_{L}^{\mathrm{u}}\right) \tag{4.5}
\end{equation*}
$$

On the other hand, the s and u-bridges $A^{\mathrm{s}}(n ; \underline{w})$ and $A^{\mathrm{u}}(n ; \underline{w})$ on $\widetilde{L}$ are defined by

$$
\begin{equation*}
B r^{\mathrm{s}}(n ; \underline{w})=\pi_{\mathcal{F}^{\mathrm{u}}}\left(A^{\mathrm{s}}(n ; \underline{w})\right), \quad B r^{\mathrm{u}}(n ; \underline{w})=\pi_{f^{-2}\left(\mathcal{F}^{\mathrm{s}}\right)}\left(A^{\mathrm{u}}(n ; \underline{w})\right), \tag{4.6}
\end{equation*}
$$

respectively. Similarly, we can also define s(u)-gaps on $L$ and $\widetilde{L}$ respectively. For instance, the maximum subinterval of $B^{\mathrm{s}}(n ; \underline{w})$ between $B^{\mathrm{s}}(n+1 ; \underline{w} 0)$ and $B^{\mathrm{s}}(n+$ $1 ; \underline{w} 1)$ is denoted by $G^{\mathrm{s}}(n ; \underline{w})$, while the maximum subinterval of $B^{\mathrm{u}}(n ; \underline{w})$ between $B^{\mathrm{u}}(n+1 ; \underline{w} 0)$ and $B^{\mathrm{u}}(n+1 ; \underline{w} 1)$ is denoted by $G^{\mathrm{u}}(n ; \underline{w})$, which are respectively called the s-gap and u-gap of generation $n$ and itinerary $\underline{w}$ on $L$.
4.2. Bounded distortion of bridges. The following lemma and its remark are useful when we estimate the ratios of the lengths of bridges with different generations. Recall that $\mathcal{U}_{F}^{r}$ is the small neighborhood of $F$ given in Section 3.2. For any $f \in \mathcal{U}_{F}^{r}$, the length of an $\operatorname{arc} J$ in $I_{f}^{\mathrm{s}}, I_{f}^{\mathrm{u}}, L_{f}$ or $\widetilde{L}_{f}$ means its arc-length, which is denoted by $|J|$.
Lemma 4.2. For any $f \in \mathcal{U}_{F}^{r}, n \in \mathbb{N}$ and $\underline{w} \in\{0,1\}^{n}$, let $B r^{\mathrm{s}}(n ; \underline{w})$ be the s-bridge of $\Lambda_{f}^{\mathrm{s}}$ and $B r^{\mathrm{u}}(n ; \underline{w})$ the u-bridge of $\Lambda_{f}^{\mathrm{u}}$, respectively. Then, for $i=0,1$, we have

$$
\begin{gather*}
\underline{\lambda} \leq \frac{\left|B r^{\mathrm{s}}(n+1 ; \underline{w} i)\right|}{\left|B r^{\mathrm{s}}(n ; \underline{w})\right|} \leq \bar{\lambda} ;  \tag{4.7}\\
\bar{\sigma}^{-1} \leq \frac{\left|B r^{\mathrm{u}}(n+1 ; \underline{w} i)\right|}{\left|B r^{\mathrm{u}}(n ; \underline{w})\right|} \leq \underline{\sigma}^{-1} . \tag{4.8}
\end{gather*}
$$

Proof. See [KS17, Lemma 4.1] for the proof.
Remark 4.3. When the generation $n$ is sufficiently large, since $\pi_{f^{-2}\left(\mathcal{F}^{\mathrm{s}}\right)}$ and $\pi_{f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)}$ are almost affine, the same conclusion also holds for s-bridges and u-bridges on $L$. Precisely, for $i=0,1$, we have that

$$
\begin{gather*}
\underline{\lambda} \leq \frac{\left|B^{\mathrm{s}}(n+1 ; \underline{w} i)\right|}{\left|B^{\mathrm{s}}(n ; \underline{w})\right|} \leq \bar{\lambda} ;  \tag{4.9}\\
\bar{\sigma}^{-1} \leq \frac{\left|B^{\mathrm{u}}(n+1 ; \underline{w} i)\right|}{\left|B^{\mathrm{u}}(n ; \underline{w})\right|} \leq \underline{\sigma}^{-1} . \tag{4.10}
\end{gather*}
$$

Let $B^{\mathrm{s}}$ be an s-bridge on $L$. For a given $\delta$ with $|\delta|$ sufficiently small, the bridge in the slid tangency curve $L(\delta)$ with the same itinerary as that of $B^{\mathrm{s}}$ is denoted by $B^{\mathrm{s}}(\delta)$ and called the $\delta$-slid s-bridge of $B^{\mathrm{s}}$. The $\delta$-slid u -bridge is defined in a similar way. Sometimes we also call them $\delta$-slid bridges for simplicity. Obviously, $\delta$-slid bridges are bridges associated to $f_{\delta}$. It follows immediately from the definition that

$$
\begin{equation*}
\lim _{\delta \rightarrow 0} B^{\mathrm{s}}(\delta)=B^{\mathrm{s}} \quad \text { and } \quad \lim _{\delta \rightarrow 0} B^{\mathrm{u}}(\delta)=B^{\mathrm{u}} \tag{4.11}
\end{equation*}
$$

The next lemma indicates that $\left|B^{\mathrm{s}}\right|$ and $\left|B^{\mathrm{s}}(\delta)\right|$ (also $\left|B^{\mathrm{u}}\right|$ and $\left|B^{\mathrm{u}}(\delta)\right|$ ) do not differ a lot when $|\delta|$ is small.
Lemma 4.4. For any $f \in \mathcal{U}_{F}^{r}$ and $\delta$ close to 0 , there is a constant $c>0$ such that, for any s-bridge $B^{\mathrm{s}}$ and u-bridge $B^{\mathrm{u}}$ on $L$ and their $\delta$-slid bridges $B^{\mathrm{s}}(\delta)$ and $B^{\mathrm{u}}(\delta)$ on $L(\delta)$, their lengths satisfy the following length estimations.
(1) $(1-c|\delta|)\left|B^{\mathrm{s}}\right| \leq\left|B^{\mathrm{s}}(\delta)\right| \leq(1+c|\delta|)\left|B^{\mathrm{s}}\right|$,
(2) $(1-c|\delta|)\left|B^{\mathrm{u}}\right| \leq\left|B^{\mathrm{u}}(\delta)\right| \leq(1+c|\delta|)\left|B^{\mathrm{u}}\right|$ and
(3) $(1-c|\delta|)\left|B^{\mathrm{s}} \cap B^{\mathrm{u}}\right|-\kappa|\delta|+O\left(\delta^{2}\right) \leq\left|B^{\mathrm{s}}(\delta) \cap B^{\mathrm{u}}(\delta)\right|$

$$
\leq(1+c|\delta|)\left|B^{\mathrm{s}} \cap B^{\mathrm{u}}\right|+\kappa|\delta|+O\left(\delta^{2}\right)
$$

where $\kappa>2$ is some constant independent of $f$ and $\delta$.
Proof. Let $\boldsymbol{a}, \boldsymbol{b} \in L$ be the endpoints of $B^{\mathrm{u}}$ and $\boldsymbol{a}_{\delta}, \boldsymbol{b}_{\delta} \in L(\delta)$ the endpoints of $B^{\mathrm{u}}(\delta)$. Obviously, by 4.11), we have

$$
\lim _{\delta \rightarrow 0} \boldsymbol{a}_{\delta}=\boldsymbol{a} \quad \text { and } \quad \lim _{\delta \rightarrow 0} \boldsymbol{b}_{\delta}=\boldsymbol{b}
$$

because the leaves of $\mathcal{F}_{f}^{\mathrm{s}}$ and $\mathcal{F}_{f}^{\mathrm{u}}$ depend continuously on $f$. See Figure 4.2. Moreover, since $L(\delta) C^{1}$ converges to $L$ as $\delta \rightarrow 0$, there exists a constant $c>0$ independent of $\delta$ such that

$$
(1-c|\delta|)|\boldsymbol{a} \boldsymbol{b}|_{L} \leq\left|\boldsymbol{a}_{\delta} \boldsymbol{b}_{\delta}\right|_{L(\delta)} \leq(1+c|\delta|)|\boldsymbol{a} \boldsymbol{b}|_{L}
$$

Figure 4.2.
where we denote the arc-lengths of the bridge $B^{\mathrm{u}} \subset L$ and $B^{\mathrm{u}}(\delta) \subset L(\delta)$ by $|\boldsymbol{a b}|_{L}$ and $\left|\boldsymbol{a}_{\delta} \boldsymbol{b}_{\delta}\right|_{L(\delta)}$ respectively. This proves (2), while (1) can be shown similarly.

Now, let us prove (3). Under the same notations as above, let $\boldsymbol{c}, \boldsymbol{d} \in L$ be the endpoints of $B^{\mathrm{s}}$ and $\boldsymbol{c}_{\delta}, \boldsymbol{d}_{\delta} \in L(\delta)$ the endpoints of $B^{\mathrm{s}}(\delta)$. Thus, we have

$$
\left|B^{\mathrm{s}} \cap B^{\mathrm{u}}\right|=|\boldsymbol{a d}|_{L} \quad \text { and } \quad\left|B^{\mathrm{s}}(\delta) \cap B^{\mathrm{u}}(\delta)\right|=\left|\boldsymbol{a}_{\delta} \boldsymbol{d}_{\delta}\right|_{L(\delta)}
$$

Let $\boldsymbol{a}^{\prime} \in L(\delta)$ be the intersection of $\mathcal{F}_{f_{\delta}}^{\mathrm{s}}\left(\boldsymbol{a}_{\delta}\right)$ and $L$, where $\mathcal{F}_{f_{\delta}}^{\mathrm{s}}\left(\boldsymbol{a}_{\delta}\right)$ is the leaf of $\mathcal{F}_{f_{\delta}}^{\mathrm{s}}$ passing through $\boldsymbol{a}_{\delta}$. Since $\boldsymbol{a}_{\delta} \boldsymbol{d}_{\delta} \subset L(\delta)$ is the $\delta$-slid segment of $\boldsymbol{a}^{\prime} \boldsymbol{d} \subset L$, by applying the same argument as that in the proof of (1) to $\boldsymbol{a}_{\delta} \boldsymbol{d}_{\delta}$ and $\boldsymbol{a}^{\prime} \boldsymbol{d}$, we get

$$
\begin{equation*}
\left|\boldsymbol{a}_{\delta} \boldsymbol{d}_{\delta}\right|_{L(\delta)} \geq(1-c|\delta|)\left|\boldsymbol{a}^{\prime} \boldsymbol{d}\right|_{L}=(1-c|\delta|)\left(|\boldsymbol{a d}|_{L}-\left|\boldsymbol{a} \boldsymbol{a}^{\prime}\right|_{L}\right) \tag{4.12}
\end{equation*}
$$

On the other hand, again by the $C^{1}$ dependence of $\boldsymbol{a}_{\delta}$ on $\delta$, we have

$$
\begin{equation*}
\left|\boldsymbol{a} \boldsymbol{a}^{\prime}\right|_{L} \leq \kappa|\delta| \tag{4.13}
\end{equation*}
$$

for some constant $\kappa>2$ which does not depend on $f$ and $\delta$. Now, (4.12) and (4.13) together imply the first inequality of (3). The other inequality of (3) can be proven similarly. This completes the proof of Lemma 4.4

## 5. Linking Lemma

Fix two bridges $B_{1}$ and $B_{2}$ on $L$, we say that they are linked or $\left(B_{1}, B_{2}\right)$ is a linked pair if $B_{1} \cap B_{2} \neq \emptyset$ and neither $B_{1}$ is contained in the interior of any gap of $B_{2}$ nor $B_{2}$ is contained in the interior of any gap of $B_{1}$. Suppose $\left(B_{1}, B_{2}\right)$ is a linked pair.

- For a given $\xi>0$, we say that $B_{1}$ and $B_{2}$ are $\xi$-linked if

$$
\left|B_{1} \cap B_{2}\right| \geq \xi \min \left\{\left|B_{1}\right|,\left|B_{2}\right|\right\}
$$

- We say that $\left(B_{1}, B_{2}\right)$ is proportional if there exists a constant $K \in(0,1)$ independent of $B_{1}$ and $B_{2}$ such that either

$$
K\left|B_{1}\right| \leq\left|B_{2}\right| \leq\left|B_{1}\right| \quad \text { or } \quad K\left|B_{2}\right| \leq\left|B_{1}\right| \leq\left|B_{2}\right|
$$

holds.

Two s-bridges $B_{1}^{\mathrm{s}}$ and $B_{2}^{\mathrm{s}}$ are called related if they are the two maximal proper subbridges of another s-bridge $B^{\mathrm{s}}$. In this case, the gap of $B^{\mathrm{s}}$ which lies between $B_{1}^{\mathrm{s}}$ and $B_{2}^{\mathrm{s}}$ is called the center gap of $B^{\mathrm{s}}$. Similar definitions can be given for u-bridges and u-gaps.

Let

$$
\xi_{0}:=\frac{(\bar{\sigma}+2)(3-\bar{\sigma})}{3(\bar{\sigma}+3)} \in(0,1)
$$

be a constant, which only depends on the neighborhood $\mathcal{U}_{F}^{r}$ above. The following lemma plays an important role in the next section. It tells us that, if we have a linked pair of bridges, then by the $\delta$-slid perturbation with $\delta$ arbitrarily small, we can obtain two new linked pairs that correspond to the sub-bridges of the original ones. The proof is based on similar versions in [CV01 and [KS17].

Lemma 5.1 (Linking Lemma). For every $f \in \mathcal{U}_{F}^{r}$, suppose ( $B^{\mathrm{s}}, B^{\mathrm{u}}$ ) is a linked pair. For every $\varepsilon>0$, there exist $\delta$ with $|\delta|<\varepsilon$, related sub-bridges $B_{1}^{\mathrm{s}}, B_{2}^{\mathrm{s}}$ of $B^{\mathrm{s}}$ and $B_{1}^{\mathrm{u}}, B_{2}^{\mathrm{u}}$ of $B^{\mathrm{u}}$ such that the pair of $\delta$-slid bridges $\left(B_{i}^{\mathrm{s}}(\delta), B_{i}^{\mathrm{u}}(\delta)\right)$ are $\xi_{0}$-linked for $i=1,2$.
Proof. Recall that $B^{\mathrm{s}(\mathrm{u})}(\delta)$ is the $\delta$-slid bridge of $B^{\mathrm{s}(\mathrm{u})}$. Thus, $B^{\mathrm{s}(\mathrm{u})}(0)$ is exactly $B^{\mathrm{s}(\mathrm{u})}$. In the following proof, we write $B^{\mathrm{s}(\mathrm{u})}(0)$ instead of $B^{\mathrm{s}(\mathrm{u})}$ for notation consistence. Let $c$ be the constant in Lemma 4.4. Fix an arbitrarily small $\varepsilon>0$. In particular, we can assume that

$$
\begin{equation*}
\frac{1-c \varepsilon}{(1+c \varepsilon)^{2}}>\underline{\lambda} \quad \text { and } \quad\left(\frac{1+c \varepsilon}{1-c \varepsilon}\right)^{2}<\frac{1}{\bar{\sigma}-2} \tag{5.1}
\end{equation*}
$$

These inequalities hold for sufficiently small $\varepsilon>0$ because $\bar{\lambda}$ and $\bar{\sigma}$ are sufficiently close to $\lambda$ and $\sigma$, respectively, which satisfy $0<\lambda<\frac{1}{2}$ and $2<\sigma<3$, see 3.1) and (3.8). Denote

$$
\begin{equation*}
\lambda_{0}:=\frac{\underline{\lambda}}{1+c \varepsilon} \quad \text { and } \quad \sigma_{0}:=\bar{\sigma}\left(\frac{1+c \varepsilon}{1-c \varepsilon}\right)^{2} . \tag{5.2}
\end{equation*}
$$

Note that when $\varepsilon>0$ is taken sufficiently small in advance, these constants $\lambda_{0}$ and $\sigma_{0}$ can be made as close to $\underline{\lambda}$ and $\bar{\sigma}$ as we want. Hence, we have

$$
\begin{equation*}
0<\lambda_{0}<\underline{\lambda}<\bar{\lambda}<1<2<\underline{\sigma}<\bar{\sigma}<\sigma_{0}<\frac{\bar{\sigma}+3}{2}<3 \tag{5.3}
\end{equation*}
$$

In addition, by the same reason, we can always assume that

$$
\begin{equation*}
\lambda_{0}\left(1+\frac{1-c \varepsilon}{1+c \varepsilon} \sigma_{0}\right)<2 \tag{5.4}
\end{equation*}
$$

To see this, since $\lambda \sigma<1$ and $2<\sigma<3$, we have

$$
\begin{equation*}
\lambda(1+\sigma)<\frac{1+\sigma}{\sigma}<\frac{1+3}{2}=2 . \tag{5.5}
\end{equation*}
$$

By shrinking $\varepsilon_{0}$ in 3.10 if necessary, we can make $\bar{\lambda}$ and $\underline{\lambda}$ (resp. $\bar{\sigma}$ and $\underline{\sigma}$ ) sufficiently close to $\lambda$ (resp. $\sigma$ ). As a result of (5.5), we have

$$
\begin{equation*}
\bar{\lambda}(1+\bar{\sigma})<2 \tag{5.6}
\end{equation*}
$$

Therefore, (5.4) follows directly from (5.6) together with the smallnesses of $\left|\sigma_{0}-\bar{\sigma}\right|$, $\left|\lambda_{0}-\underline{\lambda}\right|$ and $\varepsilon$.

Note that $\Lambda_{f_{\delta}}^{\mathrm{s}}$ and $\Lambda_{f_{\delta}}^{\mathrm{u}}$ are almost affine images of $\Lambda_{L(\delta)}^{\mathrm{s}}$ and $\Lambda_{L(\delta)}^{\mathrm{u}}$ under $\pi_{f_{\delta}^{2}\left(\mathcal{F}_{f_{\delta}}^{\mathrm{u}}\right)}$ and $\pi_{\mathcal{F}_{f_{\delta}}^{\mathrm{s}}}$ respectively (see 4.5), if $\left|B^{\mathrm{s}}(\delta)\right|$ and $\left|B^{\mathrm{u}}(\delta)\right|$ are sufficiently small, according to (3.12), we have

$$
\begin{equation*}
\tau_{f_{\delta}}^{\mathrm{s}}\left(\Lambda_{L(\delta)}^{\mathrm{s}} \cap B^{\mathrm{s}}(\delta)\right) \cdot \tau_{f_{\delta}}^{\mathrm{u}}\left(\Lambda_{L(\delta)}^{\mathrm{s}} \cap B^{\mathrm{u}}(\delta)\right)>1 \tag{5.7}
\end{equation*}
$$

for every $\delta$ with $|\delta|$ small enough. Thus, by applying Lemma 4.1 (Gap Lemma) to $\Lambda_{L(0)}^{\mathrm{s}} \cap B^{\mathrm{s}}(0)$ and $\Lambda_{L(0)}^{\mathrm{u}} \cap B^{\mathrm{u}}(0)$, there are sub-bridge $\widehat{B}^{\mathrm{s}}(0)$ of $B^{\mathrm{s}}(0)$ and sub-bridge $\widehat{B}^{\mathrm{u}}(0)$ of $B^{\mathrm{u}}(0)$ with lengths

$$
\left|\widehat{B}^{\mathrm{s}}(0)\right|=: \widehat{b}_{\mathrm{s}} \quad \text { and } \quad\left|\widehat{B}^{\mathrm{u}}(0)\right|=: \widehat{b}_{\mathrm{u}}
$$

satisfying

- $\widehat{B}^{\mathrm{s}}(0)$ and $\widehat{B}^{\mathrm{u}}(0)$ have a common point,
- $\lambda_{0}^{2} \frac{\varepsilon}{2}<\widehat{b}_{\mathrm{s}}<\lambda_{0} \frac{\varepsilon}{2}$ and
- $\frac{1+c \varepsilon}{1-c \varepsilon} \widehat{b}_{\mathrm{s}} \leq \widehat{b}_{\mathrm{u}}<\frac{1-c \varepsilon}{1+c \varepsilon} \sigma_{0} \widehat{b}_{\mathrm{s}}$.

Indeed, the second item holds because the interval $\left[\lambda_{0}^{2} \varepsilon, \lambda_{0} \varepsilon\right]$ contains a contracting fundamental domain with the contracting rate $\lambda_{0}$ which is stronger than $\underline{\lambda}$. The third item holds because the interval $\left[\frac{1+c \varepsilon}{1-c \varepsilon} \widehat{b}_{\mathrm{s}}, \frac{1-c \varepsilon}{1+c \varepsilon} \sigma_{0} \widehat{b}_{\mathrm{s}}\right]$ contains an expanding fundamental domain with expanding rate $\left(\frac{1-c \varepsilon}{1+c \varepsilon}\right)^{2} \sigma_{0}$ which is equal to $\bar{\sigma}$.

Notice that by (5.4), we have

$$
\begin{equation*}
\widehat{b}_{\mathrm{s}}+\widehat{b}_{\mathrm{u}}<\widehat{b}_{\mathrm{s}}\left(1+\frac{1-c \varepsilon}{1+c \varepsilon} \sigma_{0}\right)<\lambda_{0} \frac{\varepsilon}{2}\left(1+\frac{1-c \varepsilon}{1+c \varepsilon} \sigma_{0}\right)<\varepsilon . \tag{5.8}
\end{equation*}
$$

Let us consider the $\delta$-slid perturbation $f_{\delta}$ of $f$ with $|\delta|<\varepsilon$ such that the center of $\widehat{G}^{\mathrm{s}}(\delta)$ coincides with the center of $\widehat{G}^{\mathrm{u}}(\delta)$, where $\widehat{G}^{\mathrm{s}(\mathrm{u})}(\delta)$ is the center gap of $\widehat{B}^{\mathrm{s}(\mathrm{u})}(\delta)$. Let us denote the two related bridges (from left to right) of $\widehat{B}^{\mathrm{s}}(\delta)$ (resp. $\left.\widehat{B}^{\mathrm{u}}(\delta)\right)$ by $B_{1}^{\mathrm{s}}(\delta)$ and $B_{2}^{\mathrm{s}}(\delta)$ (resp. $B_{1}^{\mathrm{u}}(\delta)$ and $\left.B_{2}^{\mathrm{u}}(\delta)\right)$. The following claim gives us useful information on the size comparison among these bridges and gaps whose proof will be postponed until we finish the proof of the lemma.

Claim 5.2. With the notations defined above, the following inequalities hold:
(1) $\underline{\lambda}^{3} \varepsilon / 2<\left|\widehat{B}^{\mathrm{s}}(\delta)\right|<\underline{\lambda} \varepsilon / 2$,
(2) $\left|\widehat{B}^{\mathrm{s}}(\delta)\right| \leq\left|\widehat{B}^{\mathrm{u}}(\delta)\right|<\sigma_{0}\left|\widehat{B}^{\mathrm{s}}(\delta)\right|$,
(3) $\left|\widehat{G}^{\mathrm{u}}(\delta)\right|<\left|\widehat{B}^{\mathrm{s}}(\delta)\right|$.

Let us continue the proof of Lemma 5.1. We show that for $i=1,2$, these pairs $\left(B_{i}^{\mathrm{s}}(\delta), B_{i}^{\mathrm{u}}(\delta)\right)$ are proportional. Indeed, we have

$$
\begin{equation*}
\left|B_{i}^{\mathrm{s}}(\delta)\right| \leq \bar{\lambda}\left|\widehat{B}^{\mathrm{s}}(\delta)\right| \leq \bar{\lambda}\left|\widehat{B}^{\mathrm{u}}(\delta)\right|<\bar{\sigma}^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right| \leq\left|B_{i}^{\mathrm{u}}(\delta)\right|, \tag{5.9}
\end{equation*}
$$

where the second inequality follows from item (2) of Claim 5.2 and the third inequality follows from the assumption (3.11). Similarly, we also have

$$
\begin{equation*}
\left|B_{i}^{\mathrm{s}}(\delta)\right| \geq \underline{\lambda}\left|\widehat{B}^{\mathrm{s}}(\delta)\right|>\underline{\lambda} \sigma_{0}^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right|>\underline{\lambda}(a \underline{\sigma})^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right| \geq \underline{\lambda} a^{-1}\left|B_{i}^{\mathrm{u}}(\delta)\right| \tag{5.10}
\end{equation*}
$$

where $a>0$ is a constant independent of $\varepsilon$ satisfying

$$
\sigma_{0}=\bar{\sigma}\left(\frac{1+c \varepsilon}{1-c \varepsilon}\right)^{2}<\frac{\bar{\sigma}}{\bar{\sigma}-2}<a \underline{\sigma}
$$

see (5.1) and 5.2. Therefore, 5.9) and 5.10) together indicate that $\left(B_{i}^{\mathrm{s}}(\delta), B_{i}^{\mathrm{u}}(\delta)\right)$ are proportional for $i=1,2$.

In the following, we will show that $\left(B_{i}^{\mathrm{s}}(\delta), B_{i}^{\mathrm{u}}(\delta)\right)$ are $\xi_{0}$-linked for $i=1,2$. First, we notice that

$$
\begin{equation*}
\left|B_{i}^{\mathrm{s}}(\delta)\right| \leq \bar{\lambda}\left|\widehat{B}^{\mathrm{s}}(\delta)\right|<\bar{\sigma}^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right| \leq\left|B_{i}^{\mathrm{u}}(\delta)\right| \tag{5.11}
\end{equation*}
$$

which implies that

$$
\min \left\{\left|B_{i}^{\mathrm{s}}(\delta)\right|,\left|B_{i}^{\mathrm{u}}(\delta)\right|\right\}=\left|B_{i}^{\mathrm{s}}(\delta)\right|
$$

Two cases will subsequently arise: (a) $\widehat{G}^{\mathrm{s}}(\delta) \subset \widehat{G}^{\mathrm{u}}(\delta)$ and $(\mathrm{b}) \widehat{G}^{\mathrm{s}}(\delta) \supset \widehat{G}^{\mathrm{u}}(\delta)$. See Figure 5.1 .

Figure 5.1.

In case (a), for $i=1,2$, we have

$$
\begin{aligned}
\frac{\left|B_{i}^{\mathrm{s}}(\delta) \cap B_{i}^{\mathrm{u}}(\delta)\right|}{\min \left\{\left|B_{i}^{\mathrm{s}}(\delta)\right|,\left|B_{i}^{\mathrm{u}}(\delta)\right|\right\}} & =\frac{\left|B_{i}^{\mathrm{s}}(\delta) \cap B_{i}^{\mathrm{u}}(\delta)\right|}{\left|B_{i}^{\mathrm{s}}(\delta)\right|}>\frac{\frac{1}{3}\left(\left|\widehat{B}^{\mathrm{s}}(\delta)\right|-\left|\widehat{G}^{\mathrm{u}}(\delta)\right|\right)}{\bar{\lambda}\left|\widehat{B}^{\mathrm{s}}(\delta)\right|} \\
& >\frac{\frac{1}{3}\left(\left|\widehat{B}^{\mathrm{s}}(\delta)\right|-\left(1-2 \bar{\sigma}^{-1}\right)\left|\widehat{B}^{\mathrm{u}}(\delta)\right|\right)}{\bar{\sigma}^{-1}\left|\widehat{B}^{\mathrm{s}}(\delta)\right|}
\end{aligned}
$$

Note that (see item (2) of Claim 5.2

$$
\left|\widehat{B}^{\mathrm{u}}(\delta)\right| \geq\left|\widehat{B}^{\mathrm{s}}(\delta)\right|>\sigma_{0}^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right|
$$

thus the last term is greater than

$$
\frac{\frac{1}{3}\left(\sigma_{0}^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right|-\left(1-2 \bar{\sigma}^{-1}\right)\left|\widehat{B}^{\mathrm{u}}(\delta)\right|\right)}{\bar{\sigma}^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right|}
$$

Combining this fact with $\sigma_{0}^{-1}>\frac{2}{\bar{\sigma}+3}$ by (5.3), we finally obtain

$$
\frac{\left|B_{i}^{\mathrm{s}}(\delta) \cap B_{i}^{\mathrm{u}}(\delta)\right|}{\min \left\{\left|B_{i}^{\mathrm{s}}(\delta)\right|,\left|B_{i}^{\mathrm{u}}(\delta)\right|\right\}}>\frac{\sigma_{0}^{-1}-\left(1-2 \bar{\sigma}^{-1}\right)}{3 \bar{\sigma}^{-1}}>\frac{(\bar{\sigma}+2)(3-\bar{\sigma})}{3(\bar{\sigma}+3)}=\xi_{0}
$$

In case (b), it suffices to show that $B_{i}^{\mathrm{s}}(\delta)$ is not completely contained in any gap of $B_{i}^{\mathrm{u}}(\delta)$ for $i=1,2$. We argue by contradiction. Suppose that $B_{1}^{\mathrm{s}}(\delta)$ were contained in some gap $\widetilde{G}^{\mathrm{u}}(\delta)$ of $B_{1}^{\mathrm{u}}(\delta)$. Let $\widetilde{B}^{\mathrm{u}}(\delta)$ be one of the adjacent bridges of $\widetilde{G}^{\mathrm{u}}(\delta)$. That is, $\widetilde{B}^{\mathrm{u}}(\delta) \cap \widetilde{G}^{\mathrm{u}}(\delta) \neq \emptyset$ and $\operatorname{int}\left(\widetilde{B}^{\mathrm{u}}(\delta)\right) \cap \widetilde{G}^{\mathrm{u}}(\delta)=\emptyset$. Thus,

$$
\frac{\left|\widetilde{B}^{\mathrm{u}}(\delta)\right|}{\left|\widehat{G}^{\mathrm{s}}(\delta)\right|} \cdot \frac{\left|B_{1}^{\mathrm{s}}(\delta)\right|}{\left|\widetilde{G}^{\mathrm{u}}(\delta)\right|}<1 \cdot 1=1
$$

On the other hand, 5.7) gives

$$
\frac{\left|\widetilde{B}^{\mathrm{u}}(\delta)\right|}{\left|\widehat{G}^{\mathrm{s}}(\delta)\right|} \cdot \frac{\left|B_{1}^{\mathrm{s}}(\delta)\right|}{\left|\widetilde{G}^{\mathrm{u}}(\delta)\right|}=\frac{\left|\widetilde{B}^{\mathrm{u}}(\delta)\right|}{\left|\widetilde{G}^{\mathrm{u}}(\delta)\right|} \cdot \frac{\left|B_{1}^{\mathrm{s}}(\delta)\right|}{\left|\widehat{G}^{\mathrm{s}}(\delta)\right|}>\tau_{f_{\delta}}^{\mathrm{u}} \tau_{f_{\delta}}^{\mathrm{s}}>1
$$

which gives a contradiction. Similar arguments show that $B_{2}^{\mathrm{s}}(\delta)$ is not completely contained in any gap of $B_{2}^{\mathrm{u}}(\delta)$. Since $B_{i}^{\mathrm{s}}(\delta) \subset B_{i}^{\mathrm{u}}(\delta)$ for $i=1,2$, we have

$$
\frac{\left|B_{i}^{\mathrm{s}}(\delta) \cap B_{i}^{\mathrm{u}}(\delta)\right|}{\min \left\{\left|B_{i}^{\mathrm{s}}(\delta)\right|,\left|B_{i}^{\mathrm{u}}(\delta)\right|\right\}}=\frac{\left|B_{i}^{\mathrm{s}}(\delta)\right|}{\left|B_{i}^{\mathrm{s}}(\delta)\right|}=1>\xi_{0}
$$

The proof of Lemma 5.1 is completed now.
Proof of Claim 5.2. (1) By the length estimations in Lemma 4.4 and the choice of $\delta$ under (5.8), we have

$$
\left|\widehat{B}^{\mathrm{s}}(\delta)\right| \leq(1+c \varepsilon)\left|\widehat{B}^{\mathrm{s}}(0)\right|<(1+c \varepsilon) \lambda_{0} \varepsilon / 2=\underline{\lambda} \varepsilon / 2
$$

where the second inequality follows from the choice of $\widehat{b}_{\mathrm{s}}$ and the last equality follows from 5.2. Similarly,

$$
\left|\widehat{B}^{\mathrm{s}}(\delta)\right| \geq(1-c \varepsilon)\left|\widehat{B}^{\mathrm{s}}(0)\right|>(1-c \varepsilon) \lambda_{0}^{2} \varepsilon / 2>\underline{\lambda}^{3} \varepsilon / 2
$$

where the last inequality follows from (5.1) and (5.2).
(2) In the same manner as in the proof of item (1), we have

$$
\begin{aligned}
\left|\widehat{B}^{\mathrm{u}}(\delta)\right| & \geq(1-c \varepsilon)\left|\widehat{B}^{\mathrm{u}}(0)\right| \geq(1+c \varepsilon)\left|\widehat{B}^{\mathrm{s}}(0)\right| \geq\left|\widehat{B}^{\mathrm{s}}(\delta)\right| \\
\left|\widehat{B}^{\mathrm{u}}(\delta)\right| & \leq(1+c \varepsilon)\left|\widehat{B}^{\mathrm{u}}(0)\right|<(1-c \varepsilon) \sigma_{0}\left|\widehat{B}^{\mathrm{s}}(0)\right| \leq \sigma_{0}\left|\widehat{B}^{\mathrm{s}}(\delta)\right| .
\end{aligned}
$$

(3) We also have

$$
\begin{aligned}
\left|\widehat{B}^{\mathrm{s}}(\delta)\right| & >\sigma_{0}^{-1}\left|\widehat{B}^{\mathrm{u}}(\delta)\right|>\left(1-2 \bar{\sigma}^{-1}\right)\left|\widehat{B}^{\mathrm{u}}(\delta)\right| \\
& \geq\left|\widehat{B}^{\mathrm{u}}(\delta)\right|-\left(\left|\widehat{B}_{1}^{\mathrm{u}}(\delta)\right|+\left|\widehat{B}_{2}^{\mathrm{u}}(\delta)\right|\right)=\left|\widehat{G}^{\mathrm{u}}(\delta)\right|
\end{aligned}
$$

Here, the first inequality follows from item (2). To obtain the second inequality, it is enough to notice that, according to (5.1) and 5 (5.2), we have

$$
\sigma_{0}=\bar{\sigma}\left(\frac{1+c \varepsilon}{1-c \varepsilon}\right)^{2}<\frac{\bar{\sigma}}{\bar{\sigma}-2}
$$

Now, we complete the proof of Claim 5.2 .
Remark 5.3. In the proof of Lemma 5.1, we see that the size $\varepsilon$ of the perturbation can be designated in advance as small as we want. Once this $\varepsilon$ is fixed, then the sizes of the sub-bridges $\left|B_{1,2}^{\mathrm{s}}(\delta)\right|$ and $\left|B_{1,2}^{\mathrm{u}}(\delta)\right|$ are of order $\varepsilon$. More precisely, according to Claim 5.2, we have

$$
\begin{align*}
\underline{\lambda}^{4} \varepsilon / 2<\underline{\lambda}\left|\widehat{B}^{\mathrm{s}}(\delta)\right| & \leq\left|B_{1,2}^{\mathrm{s}}(\delta)\right| \leq \bar{\lambda}\left|\widehat{B}^{\mathrm{s}}(\delta)\right|<\bar{\lambda}^{2} \varepsilon / 2  \tag{5.12}\\
\left|B_{1,2}^{\mathrm{s}}(\delta)\right|<\left|B_{1,2}^{\mathrm{u}}(\delta)\right| & \leq \frac{1}{\underline{\sigma}}\left|\widehat{B}^{\mathrm{u}}(\delta)\right|<\frac{\sigma_{0}}{\underline{\sigma}}\left|\widehat{B}^{\mathrm{s}}(\delta)\right|<\underline{\lambda} \frac{\varepsilon \sigma_{0}}{2 \underline{\sigma}}<a \underline{\lambda} \frac{\varepsilon}{2}, \tag{5.13}
\end{align*}
$$

where $a>0$ is the constant defined under (5.10, which is independent of $\varepsilon$ and satisfies $\sigma_{0}<a \underline{\sigma}$.

## 6. Linear Growth Lemma

Let $f$ be an arbitrary element of $\mathcal{U}_{F}^{r}$. The following lemma allows us to obtain a sequence of linked pairs of s-bridge and u-bridge by an arbitrarily small slid perturbation such that the generations of them grow at most at a linear rate. Recall that $\xi_{0} \in(0,1)$ is the constant defined just before Lemma 5.1 .

Lemma 6.1 (Linear Growth Lemma). There exist positive constants

$$
N_{\mathrm{s}}=N_{\mathrm{s}}(\bar{\lambda}, \underline{\lambda}, \bar{\sigma}, \underline{\sigma}, \kappa) \quad \text { and } \quad N_{\mathrm{u}}=N_{\mathrm{u}}(\bar{\lambda}, \underline{\lambda}, \bar{\sigma}, \underline{\sigma}, \kappa)
$$

satisfying the following: Let $\left(B^{\mathrm{s}}(0), B^{\mathrm{u}}(0)\right)$ be a linked pair. For every $\varepsilon>0$, there exist $\Delta \in(-\varepsilon, \varepsilon)$, sequences $\left\{B_{k}^{\mathrm{s}}(\Delta)\right\}_{k \in \mathbb{N}}$ and $\left\{B_{k}^{\mathrm{u}}(\Delta)\right\}_{k \in \mathbb{N}}$ of sub-bridges of $B^{\mathrm{s}}(\Delta)$ and $B^{\mathrm{u}}(\Delta)$ respectively, such that for every $k \in \mathbb{N}$, the followings hold.
(1) The pair $\left(B_{k}^{\mathrm{s}}(\Delta), B_{k}^{\mathrm{u}}(\Delta)\right)$ is $\xi_{0} / 2$-linked. Here, $B_{k}^{\mathrm{s}, \mathrm{u}}(\Delta)$ is the s , u-bridges on $L(\Delta)$ with respect to $f_{\Delta}$.
(2) Let $s_{k}, u_{k}$ be the generations of $B_{k}^{\mathrm{s}}, B_{k}^{\mathrm{u}}$, then

$$
s_{k+1}-s_{k} \leq N_{\mathrm{s}} \quad \text { and } \quad u_{k+1}-u_{k} \leq N_{\mathrm{u}} .
$$

Proof. Fix an arbitrarily small $\varepsilon>0$. The following proof will be divided into four steps.

Step 1. In this step, we will prove the following claim.
Claim 6.2. For every $k \in \mathbb{N}$, there exist $\Delta_{k} \in \mathbb{R}$ and $\xi_{0}$-linked pairs $\left(B_{t}^{\mathrm{s}}\left(\Delta_{k}\right), B_{t}^{u}\left(\Delta_{k}\right)\right)$ $(t=1, \ldots, k)$ in $L\left(\Delta_{k}\right)$ such that $B_{t}^{\mathrm{s}(\mathrm{u})}\left(\Delta_{k}\right)(t=1, \ldots, k)$ are pairwise disjoint.

We will construct this sequence of linked pairs by induction. First, since $B^{\mathrm{s}}(0)$ and $B^{\mathrm{u}}(0)$ are linked, we are allowed to apply Lemma 5.1 to this pair. For $\varepsilon>0$ fixed before, there are $\delta_{1}$ with $\left|\delta_{1}\right|<\varepsilon / 2$, sub-bridges $B_{1}^{\mathrm{s}}, B_{1}^{\mathrm{s}}$ of $B^{\mathrm{s}}(0)$, and $B_{1}^{\mathrm{u}}, \widetilde{B}_{1}^{\mathrm{u}}$ of $B^{\mathrm{u}}(0)$ such that

$$
\left(B_{1}^{\mathrm{s}}\left(\delta_{1}\right), B_{1}^{\mathrm{u}}\left(\delta_{1}\right)\right) \quad \text { and } \quad\left(\widetilde{B}_{1}^{\mathrm{s}}\left(\delta_{1}\right), \widetilde{B}_{1}^{\mathrm{u}}\left(\delta_{1}\right)\right)
$$

are $\xi_{0}$-linked pairs. Let $\Delta_{1}:=\delta_{1}$, then $\left(B_{1}^{\mathrm{s}}\left(\Delta_{1}\right), B_{1}^{\mathrm{u}}\left(\Delta_{1}\right)\right)$ is exactly the first pair of the sequence that we desired in the statement of Claim 6.2, while the other pair $\left(\widetilde{B}_{1}^{\mathrm{s}}\left(\Delta_{1}\right), \widetilde{B}_{1}^{\mathrm{u}}\left(\Delta_{1}\right)\right)$ will be used for constructing the next pair. Moreover, by Remark 5.3, we also have the length estimation

$$
\begin{equation*}
\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right|<\bar{\lambda}^{2} \varepsilon / 2 \tag{6.1}
\end{equation*}
$$

Suppose by induction that for some $k \geq 1$, we have found $\left(B_{k}^{\mathrm{s}}\left(\Delta_{k}\right), B_{k}^{\mathrm{u}}\left(\Delta_{k}\right)\right)$ and $\left(\widetilde{B}_{k}^{\mathrm{s}}\left(\Delta_{k}\right), \widetilde{B}_{k}^{\mathrm{u}}\left(\Delta_{k}\right)\right)$, both of which are $\xi_{0}$-linked, where $\Delta_{k}=\delta_{1}+\cdots+\delta_{k}$. Let $s_{k}$ and $u_{k}$ denote the generations of $B_{k}^{\mathrm{s}}$ and $B_{k}^{\mathrm{u}}$ respectively, and note that $B_{k}^{\mathrm{s}}$ and $\widetilde{B}_{k}^{\mathrm{s}}\left(\widetilde{B}^{\text {resp. }} B_{k}^{\mathrm{u}}\right.$ and $\left.\widetilde{B}_{k}^{\mathrm{u}}\right)$ have the same generations. Next, by applying Lemma 5.1 to $\left(\widetilde{B}_{k}^{\mathrm{s}}\left(\Delta_{k}\right), \widetilde{B}_{k}^{\mathrm{u}}\left(\Delta_{k}\right)\right)$ for

$$
\begin{equation*}
\varepsilon_{k}:=\frac{\bar{\lambda} \xi_{0}}{4(\kappa+1)}\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right| \tag{6.2}
\end{equation*}
$$

where $\kappa$ is the constant in Lemma 4.4, there exist $\delta_{k+1}$ with $\left|\delta_{k+1}\right|<\varepsilon_{k}$ and subbridges

$$
\begin{array}{lll}
B_{k+1}^{\mathrm{s}}\left(\Delta_{k}+\delta_{k+1}\right), & \widetilde{B}_{k+1}^{\mathrm{s}}\left(\Delta_{k}+\delta_{k+1}\right) & \text { of } \widetilde{B}_{k}^{\mathrm{s}}\left(\Delta_{k}+\delta_{k+1}\right) \\
B_{k+1}^{\mathrm{u}}\left(\Delta_{k}+\delta_{k+1}\right), & \widetilde{B}_{k+1}^{\mathrm{u}}\left(\Delta_{k}+\delta_{k+1}\right) & \text { of } \widetilde{B}_{k}^{\mathrm{u}}\left(\Delta_{k}+\delta_{k+1}\right)
\end{array}
$$

of generations $s_{k+1}$ and $u_{k+1}$ respectively such that

$$
\left(B_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right), B_{k+1}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right) \quad \text { and } \quad\left(\widetilde{B}_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right), \widetilde{B}_{k+1}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right)
$$

are $\xi_{0}$-linked pairs, where we define $\Delta_{k+1}:=\Delta_{k}+\delta_{k+1}$. Notice that $B_{k+1}^{\mathrm{s}(\mathrm{u})}$ is contained inside $\widetilde{B}_{k}^{\mathrm{s}(\mathrm{u})}$ which is disjoint with $B_{k}^{\mathrm{s}(\mathrm{u})}$, thus, $B_{t}^{\mathrm{s}(\mathrm{u})}(t=1, \ldots, k)$ are obviously pairwise disjoint. Moreover, we see that according to the above process, sub-bridges $B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)$ and $B_{t}^{\mathrm{u}}\left(\Delta_{k+1}\right)$ are also well-defined for every $t=1,2, \ldots, k$. Indeed, we have

$$
\begin{aligned}
B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right) & :=B_{t}^{\mathrm{s}}\left(\Delta_{t}+\delta_{t+1}+\cdots+\delta_{k+1}\right) \\
B_{t}^{\mathrm{u}}\left(\Delta_{k+1}\right) & :=B_{t}^{\mathrm{u}}\left(\Delta_{t}+\delta_{t+1}+\cdots+\delta_{k+1}\right)
\end{aligned}
$$

In addition, by applying Lemma 4.4 finite many times, we have the following estimation which will be useful in Step 4 .

$$
\begin{align*}
\left|B_{k+1}^{\mathrm{S}}\left(\Delta_{k+1}\right)\right| & \leq \bar{\lambda}^{s_{k+1}-s_{k}}\left|B_{k}^{\mathrm{S}}\left(\Delta_{k+1}\right)\right| \\
& \leq \bar{\lambda}^{s_{k+1}-s_{k}}\left|B_{k}^{\mathrm{S}}\left(\Delta_{k}\right)\right|\left(1+c \delta_{k+1}\right)  \tag{6.3}\\
& \leq \cdots \leq \bar{\lambda}^{s_{k+1}-s_{1}}\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right| \prod_{i=2}^{k+1}\left(1+c \delta_{i}\right) .
\end{align*}
$$

This completes the proof of Claim 6.2 .
Step 2. For every $k \in \mathbb{N}$, let us denote

$$
\xi_{k}:=\xi_{0}\left(1-\frac{1}{2} \sum_{i=1}^{k} \bar{\lambda}^{i}\right)
$$

It is clear that $\xi_{k}>\xi_{0} / 2$ for every $k \in \mathbb{N}$. In this step, we will prove the following claim.

Claim 6.3. For every $k \in \mathbb{N}$, the pair $\left(B_{t}^{\mathbf{s}}\left(\Delta_{k}\right), B_{t}^{\mathrm{u}}\left(\Delta_{k}\right)\right)$ are $\xi_{k-t}$-linked for every $t=1,2, \ldots, k$.

The proof of Claim 6.3 will be given by induction on $k$. When $k=1$, the only case we need to consider is $t=1$. The conclusion follows directly from Claim 6.2 , Suppose the conclusion of Claim 6.3 holds for $k$, in the following, we will show that $\left(B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right), B_{t}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right)$ are $\xi_{k+1-t}$-linked for every $t=1,2, \ldots, k+1$.

When $t=k+1$, by the construction of $\left(B_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right), B_{k+1}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right)$ in Step 1, we are done, since this pair is $\xi_{0}$-linked. Thus, it suffices to set $t \in\{1,2, \ldots, k\}$. Then, we have

$$
\begin{aligned}
\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right) \cap B_{t}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right| & \geq\left(1-c \delta_{k+1}\right)\left|B_{t}^{\mathrm{s}}\left(\Delta_{k}\right) \cap B_{t}^{\mathrm{u}}\left(\Delta_{k}\right)\right|-\kappa \delta_{k+1}-O\left(\delta_{k+1}^{2}\right) \\
& \geq\left(1-c \delta_{k+1}\right) \xi_{k-t}\left|B_{t}^{\mathrm{s}}\left(\Delta_{k}\right)\right|-\kappa \delta_{k+1}-O\left(\delta_{k+1}^{2}\right) \\
& \geq\left(1-c \delta_{k+1}\right) \xi_{k-t} \frac{\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|}{1+c \delta_{k+1}}-\kappa \delta_{k+1}-O\left(\delta_{k+1}^{2}\right) \\
& =\xi_{k-t}\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|-\delta_{k+1}\left(\kappa+2 c \xi_{k-t}\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|+O\left(\delta_{k+1}\right)\right)
\end{aligned}
$$

Here, we have applied Lemma 4.4 in the first and third inequalities, while the second inequality is obtained according to the induction hypothesis. If $\varepsilon$ is fixed sufficiently small in advance, then we are allowed to bound the coefficient of $\delta_{k+1}$ in the last line from above by $(\kappa+1)$. Indeed, $\sqrt{6.2}$ gives that $\left|\delta_{k+1}\right|<\varepsilon_{k}=O\left(\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right|\right)$.

Moreover, both of $\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|$ and $\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right|$ are bounded from above by $\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right|=$ $O(\varepsilon)$ as $\varepsilon$ tends to zero. Thus,

$$
\left|\kappa+2 c \xi_{k-t}\right| B_{t}^{s}\left(\Delta_{k+1}\right)\left|+O\left(\delta_{k+1}\right)\right|<\kappa+1
$$

for every $\varepsilon>0$ small enough.
Hence it follows that

$$
\begin{align*}
\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right) \cap B_{t}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right| & \geq \xi_{k-t}\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|-(\kappa+1) \delta_{k+1} \\
& =\left(\xi_{k-t}-\frac{(\kappa+1) \delta_{k+1}}{\left|B_{t}^{\mathrm{S}}\left(\Delta_{k+1}\right)\right|}\right)\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right| \tag{6.4}
\end{align*}
$$

By bounded distortion property (see Lemma 4.2 and Remark 4.3), we have

$$
\frac{\left|B_{k}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|}{\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|} \leq \bar{\lambda}^{s_{k}-s_{t}}
$$

because $s_{k}$ is the generation of $B_{k}^{\mathrm{s}}\left(\Delta_{k+1}\right)$. Thus, by recalling 6.2 and noticing that $1-c\left|\delta_{k+1}\right|>1 / 2$, we have

$$
\begin{align*}
\frac{(\kappa+1) \delta_{k+1}}{\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|} & \leq(\kappa+1) \frac{\bar{\lambda} \xi_{0}}{4(\kappa+1)} \frac{\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right|}{\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|} \leq \frac{\bar{\lambda} \xi_{0}}{4\left(1-c\left|\delta_{k+1}\right|\right)} \frac{\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right|}{\left|B_{t}^{\mathrm{s}}\left(\Delta_{k}\right)\right|}  \tag{6.5}\\
& \leq \frac{\bar{\lambda} \xi_{0}}{2} \bar{\lambda}^{s_{k}-s_{t}} \leq \frac{\bar{\lambda} \xi_{0}}{2} \bar{\lambda}^{k-t}=\frac{\xi_{0}}{2} \bar{\lambda}^{k+1-t}
\end{align*}
$$

In the last inequality, we used the obvious relation that

$$
s_{k}-s_{t} \geq k-t
$$

Therefore, by substituting (6.5) into (6.4), and by recalling that $\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right| \leq$ $\left|B_{t}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right|$ according to the proof of Lemma 5.1 (see (5.11), we get

$$
\begin{aligned}
\frac{\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right) \cap B_{t}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right|}{\left|B_{t}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|} & \geq \xi_{k-t}-\frac{\xi_{0}}{2} \bar{\lambda}^{k+1-t} \\
& =\xi_{0}\left(1-\frac{1}{2} \sum_{i=1}^{k-t} \bar{\lambda}^{i}\right)-\frac{\xi_{0}}{2} \bar{\lambda}^{k+1-t} \\
& =\xi_{k+1-t} .
\end{aligned}
$$

This completes the proof of Claim 6.3 .
Step 3. In this step, we will finish the construction of $\left(B_{k}^{\mathrm{s}}(\Delta), B_{k}^{\mathrm{u}}(\Delta)\right)_{k \in \mathbb{N}}$ for a uniform constant $\Delta$ which is independent of $k$.

For every integer $k \geq 2$, by recalling the construction of $\left(B_{t}^{\mathrm{s}}\left(\Delta_{k}\right), B_{k}^{\mathrm{u}}\left(\Delta_{k}\right)\right)(t=$ $1, \ldots, k$ ) in Step 1, we have the following estimation (see 6.3) )

$$
\begin{align*}
\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right| & \leq \bar{\lambda}^{s_{k}-s_{k-1}}\left|B_{k-1}^{\mathrm{S}}\left(\Delta_{k}\right)\right| \leq \bar{\lambda}^{s_{k}-s_{k-1}}\left(1+c \delta_{k}\right)\left|B_{k-1}^{\mathrm{s}}\left(\Delta_{k-1}\right)\right| \\
& \leq \cdots \leq \bar{\lambda}^{s_{k}-s_{1}}\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right| \prod_{i=2}^{k}\left(1+c \delta_{i}\right) \\
& \leq \bar{\lambda}^{k-1}\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right| \prod_{i=2}^{k}\left(1+c \delta_{i}\right)=\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right| \prod_{i=2}^{k}\left[\bar{\lambda}\left(1+c \delta_{i}\right)\right]  \tag{6.6}\\
& \leq\left|B_{1}^{\mathrm{S}}\left(\Delta_{1}\right)\right|\left(\frac{3}{4}\right)^{k-1}
\end{align*}
$$

where the last inequality holds since $\bar{\lambda}<1 / 2$ and $1+c \delta_{i}<3 / 2$ for a small $\varepsilon$. Notice that 6.6 holds for $k=1$ as well.

Now, we are in the position to define

$$
\Delta=\lim _{k \rightarrow \infty} \Delta_{k}=\sum_{k=1}^{\infty} \delta_{k}
$$

By substituting 6.6 into

$$
\begin{equation*}
\left|\delta_{k+1}\right| \leq \varepsilon_{k}=\frac{\bar{\lambda} \xi_{0}}{4(\kappa+1)}\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right| \tag{6.7}
\end{equation*}
$$

and combining it with $\bar{\lambda}<1 / 2<3 / 4$ and $\kappa>2$, we obtain

$$
\begin{aligned}
|\Delta| \leq \sum_{k=1}^{\infty}\left|\delta_{k}\right| & =\left|\delta_{1}\right|+\sum_{k=1}^{\infty}\left|\delta_{k+1}\right| \\
& \leq \frac{\varepsilon}{2}+\sum_{k=1}^{\infty} \frac{\bar{\lambda} \xi_{0}}{4(\kappa+1)}\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right|\left(\frac{3}{4}\right)^{k-1} \\
& <\frac{\varepsilon}{2}+\frac{\xi_{0}}{4(\kappa+1)}\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right| \sum_{k=1}^{\infty}\left(\frac{3}{4}\right)^{k} \\
& \leq \frac{\varepsilon}{2}+\frac{\xi_{0}}{4}\left|B_{1}^{\mathrm{s}}\left(\Delta_{1}\right)\right| \leq \varepsilon
\end{aligned}
$$

Here, we have applied 6.1) in the last inequality. This estimation shows that $\left\{B_{k}^{\mathrm{s}}\left(\Delta_{l}\right)\right\}_{l \in \mathbb{N}}$ and $\left\{B_{k}^{\mathrm{u}}\left(\Delta_{l}\right)\right\}_{l \in \mathbb{N}}$ are Cauchy sequences of compact sets with respect to the Hausdorff metric. Thus, we are allowed to define, for every $k \in \mathbb{N}$, that

$$
B_{k}^{\mathrm{s}}(\Delta):=\lim _{l \rightarrow \infty} B_{k}^{\mathrm{s}}\left(\Delta_{l}\right) \quad \text { and } \quad B_{k}^{\mathrm{u}}(\Delta):=\lim _{l \rightarrow \infty} B_{k}^{\mathrm{u}}\left(\Delta_{l}\right)
$$

Note that $\xi_{k}$ has a uniform lower bound $\xi_{0} / 2$ as we mentioned in the beginning of Step 2. By taking the limit, Claim 6.3 implies that $\left(B_{k}^{\mathrm{s}}(\Delta), B_{k}^{\mathrm{u}}(\Delta)\right)$ is $\xi_{0} / 2$-linked for every $k \in \mathbb{N}$ as we desired in Lemma 6.1 (1).

Step 4. Finally, let us show (2). Since $B_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right)$ is obtained by applying Lemma 5.1 to $\left(\widetilde{B}_{k}^{\mathrm{s}}\left(\Delta_{k}\right), \widetilde{B}_{k}^{\mathrm{u}}\left(\Delta_{k}\right)\right)$ for $\varepsilon_{k}($ see $(6.2)$ ), hence Remark 5.3 gives

$$
\begin{align*}
\left|B_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right| & \geq \underline{\lambda}^{4} \varepsilon_{k} / 2=\underline{\lambda}^{4} \frac{\bar{\lambda} \xi_{0}}{8(\kappa+1)}\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right| \geq \frac{\underline{\lambda}^{5} \xi_{0}}{8(\kappa+1)}\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right| \\
& \geq \frac{\underline{\lambda}^{5} \xi_{0}}{8(\kappa+1)\left(1+c \delta_{k+1}\right)}\left|B_{k}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right| \geq \frac{\underline{\lambda}^{5} \xi_{0}}{12(\kappa+1)}\left|B_{k}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right| \tag{6.8}
\end{align*}
$$

where in the last inequality, we have used the estimation $1+c \delta_{k+1}<3 / 2$. It follows that (refer to Lemma 4.2 and Remark 4.3 )

$$
\bar{\lambda}^{s_{k+1}-s_{k}} \geq \frac{\left|B_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|}{\left|B_{k}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right|} \geq \frac{\underline{\lambda}^{5} \xi_{0}}{12(\kappa+1)}
$$

which gives

$$
s_{k+1}-s_{k} \leq(\log \bar{\lambda})^{-1} \log \frac{\underline{\lambda}^{5} \xi_{0}}{12(\kappa+1)}=: N_{\mathrm{s}}
$$

as desired.

Next, we consider the case of u-bridges. Recall that $\left(B_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right), B_{k+1}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right)$ is the proportional pair obtained by using Lemma 5.1. It follows that

$$
\begin{aligned}
\left|B_{k+1}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right| & \geq\left|B_{k+1}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right| \geq \frac{\underline{\lambda}^{5} \xi_{0}}{12(\kappa+1)}\left|B_{k}^{\mathrm{s}}\left(\Delta_{k+1}\right)\right| \\
& \geq \frac{\underline{\lambda}^{5} \xi_{0}}{12(\kappa+1)}\left(1-c \delta_{k+1}\right)\left|B_{k}^{\mathrm{s}}\left(\Delta_{k}\right)\right| \\
& \geq \frac{\underline{\lambda}^{5} \xi_{0}}{12(\kappa+1)}\left(1-c \delta_{k+1}\right) \underline{\lambda} a^{-1}\left|B_{k}^{\mathrm{u}}\left(\Delta_{k}\right)\right| \\
& \geq \frac{\underline{\lambda}^{5} \xi_{0}}{12(\kappa+1)}\left(1-c \delta_{k+1}\right) \underline{\lambda} a^{-1} \frac{\left|B_{k}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right|}{\left(1+c \delta_{k+1}\right)}
\end{aligned}
$$

where the first and fourth inequalities follow from (5.9) and 5.10 , the third and fifth inequalities follow from Lemma 4.4 , and the second inequality is given by $(6.8)$. Therefore, we have the following estimations for the u-bridges as well.

$$
\left(\underline{\sigma}^{-1}\right)^{u_{k+1}-u_{k}} \geq \frac{\left|B_{k+1}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right|}{\left|B_{k}^{\mathrm{u}}\left(\Delta_{k+1}\right)\right|} \geq \frac{\underline{\lambda}^{6} \xi_{0}\left(1-c \delta_{k+1}\right)}{12 a(\kappa+1)\left(1+c \delta_{k+1}\right)} \geq \frac{\underline{\lambda}^{6} \xi_{0}}{36 a(\kappa+1)}
$$

which gives

$$
u_{k+1}-u_{k} \leq(-\log \underline{\sigma})^{-1} \log \frac{\underline{\lambda}^{6} \xi_{0}}{36 a(\kappa+1)}=: N_{\mathrm{u}}
$$

The proof of Lemma 6.1 is completed now.

## 7. Critical Chain Lemma

Suppose that $\left\{a_{k}\right\}$ and $\left\{b_{k}\right\}$ are two sequences of positive numbers. We introduce the following notations:

- $a_{k} \lesssim b_{k}$ means that there exists some positive constant $K_{1}$ independent of $k$ such that $a_{k} \leq K_{1} b_{k}$ for every $k$;
- $a_{k} \gtrsim b_{k}$ means that there exists some positive constant $K_{2}$ independent of $k$ such that $a_{k} \geq K_{2} b_{k}$ for every $k$;
- $a_{k} \sim b_{k}$ means that $a_{k} \lesssim b_{k}$ and $a_{k} \gtrsim b_{k}$. In other words, there exist positive constants $K_{1}, K_{2}$ such that $K_{2} \leq a_{k} / b_{k} \leq K_{1}$ for every $k$.
For a sequence of closed intervals $\left[a_{k}, b_{k}\right]$ on $\mathbb{R}$ and $\rho>0$, we say that $\left[a_{k}, b_{k}\right]$ are $\rho$-uniformly pairwise disjoint if

$$
(1+\rho)\left[a_{k}, b_{k}\right]:=\left[a_{k}-\rho\left(b_{k}-a_{k}\right), b_{k}+\rho\left(b_{k}-a_{k}\right)\right]
$$

are pairwise disjoint for all $k$. We say that $\left[a_{k}, b_{k}\right]$ are uniformly pairwise disjoint if $\left[a_{k}, b_{k}\right]$ are $\rho$-uniformly pairwise disjoint for some $\rho>0$. Similar definitions can also be given for sequences of intervals on $C^{1}$ arcs.

Let $\phi$ be a non-decreasing $C^{\infty}$ function defined on $\mathbb{R}$ satisfying

$$
\phi(x)= \begin{cases}0 & \text { if } x \leq-1  \tag{7.1}\\ 1 & \text { if } x \geq 0\end{cases}
$$

Given $\rho>0$ and an interval $[a, b]$, let

$$
\phi_{\rho,[a, b]}(x):=\phi\left(\frac{x-a}{\rho(b-a)}\right)+\phi\left(\frac{b-x}{\rho(b-a)}\right)-1
$$

Thus, $\phi_{\rho,[a, b]}$ is a non-negative $C^{\infty}$ function on $\mathbb{R}$ satisfying

- $\operatorname{supp}\left(\phi_{\rho,[a, b]}\right) \subset(1+\rho)[a, b]$,
- $\phi_{\rho,[a, b]}(x)=1$ for every $x \in[a, b]$,
- $\phi_{\rho,[a, b]}(x) \in[0,1]$ for every $x \in \mathbb{R}$,
- $\left\|\phi_{\rho,[a, b]}\right\|_{C^{r}} \leq(\rho(b-a))^{-r}\|\phi\|_{C^{r}}$ if $\rho(b-a) \leq 1$.

Bump functions of this type will be used later for constructing $C^{r}$-perturbations.
7.1. An open subset $\mathcal{U}_{0}$ of $\mathcal{U}_{F}^{r}$. In this subsection, we will select an element $F_{0}$ and a neighborhood $\mathcal{U}_{0} \subset \mathcal{U}_{F}^{r}$ of $F_{0}$. They are exactly the diffeomorphism and the open set in the statement of Theorem A. Let us Recall that $\mathcal{U}_{F}^{r}$ is the small neighborhood of $F$ fixed in Section 3 . For every $f \in \mathcal{U}_{F}^{r}$, the tangency curve between $\mathcal{F}^{\mathrm{s}}$ and $f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)$ is $L_{f}$.

Claim 7.1. There exist $F_{0} \in \mathcal{U}_{F}^{r}$ and a neighborhood $\mathcal{U}_{0} \subset \mathcal{U}_{F}^{r}$ of $F_{0}$ satisfying the following conditions: For every $f \in \mathcal{U}_{0}$, there is a linked pair $\left(B^{\mathbf{s}}, B^{\mathrm{u}}\right)$ on its tangency curve $L_{f}$.
Proof. First, let us consider the center diffeomorphism $F$ described in Section 3.1 . One easily sees that its tangency curve $L_{F}$ lies exactly on the $x$-axis $\{y=0\}$. Let us define

$$
n_{0}:=\min \left\{n \in \mathbb{N}: 2 a_{\mathrm{u}} \sigma^{-(n+1)} \leq \mu\right\}, m_{0}:=\min \left\{m \in \mathbb{N}: 2 a_{\mathrm{s}} \gamma \lambda^{m+1} \leq \mu\right\}
$$

Thus, $B_{0}^{\mathrm{u}}:=B^{\mathrm{u}}\left(n_{0} ; 00 \ldots 0\right) \subset\{y=0\}$ has its left boundary at $-a_{\mathrm{u}}$ and the right boundary at the right of $-a_{\mathrm{u}}+\mu$. Similarly, $B_{0}^{\mathrm{s}}:=B^{\mathrm{s}}\left(m_{0} ; 00 \ldots 0\right) \subset\{y=0\}$ has its right boundary at $-a_{\mathrm{u}}+\mu$ and the left boundary at the left of $-a_{\mathrm{u}}$. It then follows that $\left|B_{0}^{\mathrm{s}} \cap B_{0}^{\mathrm{u}}\right|=\mu$ and neither $B_{0}^{\mathrm{s}}$ is contained in the interior of any gap of $B_{0}^{\mathrm{u}}$ nor $B_{0}^{\mathrm{u}}$ is contained in the interior of any gap of $B_{0}^{\mathrm{s}}$. Since $\tau^{\mathrm{s}} \tau^{\mathrm{u}}>1$ by (3.6), according to Lemma 4.1 (Gap Lemma), we are allowed to find a point $\boldsymbol{x}$ in $\left(\Lambda_{L_{F}}^{\mathrm{s}} \cap B_{0}^{\mathrm{s}}\right) \cap\left(\Lambda_{L_{F}}^{\mathrm{u}} \cap B_{0}^{\mathrm{u}}\right)$ where $\Lambda_{L_{F}}^{\mathrm{s}}$ and $\Lambda_{L_{F}}^{\mathrm{u}}$ are Cantor sets on $L_{F}$ defined by 4.5). Note that both $\Lambda_{L_{F}}^{\mathrm{s}}$ and $\Lambda_{L_{F}}^{\mathrm{u}}$ are Cantor sets hence $\boldsymbol{x}$ is not an isolated point of them. Therefore, by perturbing $\mu$ of (3.9) a little bit, precisely, by considering $\mu+c$ instead of $\mu$ for some $c$ with $|c|$ very small, we obtain the $c$-slid perturbation of $F$, denoted by $F_{0}$, such that there exist sub-bridges $B_{F_{0}}^{\mathrm{s}} \subset \operatorname{Int}\left(L_{F_{0}}\right)$ of $B_{0}^{\mathrm{s}}$ and $B_{F_{0}}^{\mathrm{u}} \subset \operatorname{Int}\left(L_{F_{0}}\right)$ of $B_{0}^{\mathrm{u}}$ around $\boldsymbol{x}$, satisfying
(i) $B_{F_{0}}^{\mathrm{s}}$ is not contained in the interior of any gap of $B_{F_{0}}^{\mathrm{u}}$,
(ii) $B_{F_{0}}^{\mathrm{u}}$ is not contained in the interior of any gap of $B_{F_{0}}^{\mathrm{s}}$,
(iii) $\left|B_{F_{0}}^{\mathrm{s}} \cap B_{F_{0}}^{\mathrm{u}}\right|>0$.

Suppose

$$
B_{F_{0}}^{\mathrm{s}}=B_{F_{0}}^{\mathrm{s}}(s ; \underline{w}), \quad B_{F_{0}}^{\mathrm{u}}=B_{F_{0}}^{\mathrm{u}}(u ; \underline{z})
$$

for some $\underline{w} \in\{0,1\}^{s}$ and $\underline{z} \in\{0,1\}^{u}$. Here, we add the subscript $F_{0}$ in the notations in order to emphasize that they are the $\mathrm{s}(\mathrm{u})$-bridges with respect to $F_{0}$.

Now, let us take an arbitrary $f$ in a neighborhood $\mathcal{U}_{0} \subset \mathcal{U}_{F}^{r}$ of $F_{0}$. As long as $\mathcal{U}_{0}$ is fixed small enough, the above three conditions (i)-(iii) also hold for bridges

$$
B^{\mathrm{s}}:=B^{\mathrm{s}}(s ; \underline{w}) \subset L_{f}, \quad B^{\mathrm{u}}:=B^{\mathrm{u}}(u ; \underline{z}) \subset L_{f}
$$

of every $f \in \mathcal{U}_{0}$. We conclude that these bridges are the desired linked pair for $f$, which completes the proof of the claim.

Remark 7.2. According to the proof of Claim 7.1, it is not hard to see that $\mathcal{U}_{0}$ can be chosen arbitrarily close to $F$. Indeed, it suffices to select $c$ with $|c|$ sufficiently small in the proof.

As a consequence of this claim, for every $f \in \mathcal{U}_{0}$, Lemma 6.1 can be applied to $f$ and this linked pair. Let $\Delta=\Delta(\varepsilon)$ be the constant obtained by Lemma 6.1 (Linear Growth Lemma). By selecting $\varepsilon>0$ sufficiently small in advance, we can certainly require that $f_{\Delta}$ is still contained in $\mathcal{U}_{0}$. For notational simplicity, from now on, let us denote the $\Delta$-slid perturbation $f_{\Delta}$ of $f$ by $f$ again.

Since $f$ satisfies the conclusion of Lemma 6.1, there exists a sequence of $\xi_{0} / 2$ linked pairs $\left(B_{k}^{\mathrm{s}}, B_{k}^{\mathrm{u}}\right)$ with generations $\left(s_{k}, u_{k}\right)$ respectively. In particular, $s_{k}$ and $u_{k}$ satisfy Lemma 6.1 (2). Let us fix a large number $N$. In particular, we assume that $N$ is much larger than $\max \left\{N_{\mathrm{s}}, N_{\mathrm{u}}\right\}$. For every $k \in \mathbb{N}$, since $\left(B_{k}^{\mathrm{s}}, B_{k}^{\mathrm{u}}\right)$ is a linked pair, by applying Lemma 4.1 (Gap Lemma) to $\Lambda_{L}^{\mathrm{s}} \cap B_{k}^{\mathrm{s}}$ and $\Lambda_{L}^{\mathrm{u}} \cap B_{k}^{\mathrm{u}}$, there exist linked sub-bridges

$$
\begin{equation*}
\widehat{B}_{k}^{\mathrm{s}}:=\widehat{B}_{k}^{\mathrm{s}}\left(\widehat{s}_{k} ; \widehat{\widehat{w}}^{(k)}\right) \subset B_{k}^{\mathrm{s}}, \quad \widehat{B}_{k}^{\mathrm{u}}:=\widehat{B}_{k}^{\mathrm{u}}\left(\widehat{u}_{k} ; \widehat{\widehat{z}}^{(k)}\right) \subset B_{k}^{\mathrm{u}} \tag{7.2}
\end{equation*}
$$

whose lengths satisfy

$$
\begin{equation*}
\underline{\lambda}^{2} \cdot \underline{\lambda}^{k N} \leq\left|\widehat{B}_{k}^{\mathrm{s}}\right| \leq \underline{\lambda} \cdot \underline{\lambda}^{k N}, \quad\left|\widehat{B}_{k}^{\mathrm{s}}\right| \leq\left|\widehat{B}_{k}^{\mathrm{u}}\right| \leq \bar{\sigma}\left|\widehat{B}_{k}^{\mathrm{s}}\right| \tag{7.3}
\end{equation*}
$$

It is easy to see that $\widehat{s}_{k}, \widehat{u}_{k} \rightarrow \infty$ when $k$ tends to infinity. Now, for an arbitrary $\widehat{m}_{k} \in \mathbb{N}$, let us define a new itinerary

$$
\begin{equation*}
\underline{z}^{(k)}:=\underline{\widehat{z}}^{(k)} \widehat{\widehat{v}}^{(k)}\left[\underline{\widehat{w}}^{(k+1)}\right]^{-1} \tag{7.4}
\end{equation*}
$$

with length

$$
\begin{equation*}
n_{k}=\widehat{u}_{k}+\widehat{m}_{k}+\widehat{s}_{k+1} \tag{7.5}
\end{equation*}
$$

where $\widehat{\widehat{v}}^{(k)}$ is an arbitrary element of $\{0,1\}^{\widehat{m}_{k}}$. Consider the sub-bridges

$$
\begin{equation*}
\mathscr{B}_{k}^{\mathrm{s}}:=B^{\mathrm{s}}\left(n_{k-1} ;\left[\underline{z}^{(k-1)}\right]^{-1}\right) \subset \widehat{B}_{k}^{\mathrm{s}} \quad \text { and } \quad \mathscr{B}_{k}^{\mathrm{u}}:=B^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right) \subset \widehat{B}_{k}^{\mathrm{u}} \tag{7.6}
\end{equation*}
$$

Here, the non-consistence of subscript in the definition of $\mathscr{B}_{k}^{s}$ is caused by the definition of $\underline{z}^{(k)}$ in (7.4). Let us remark that although $\widehat{B}_{k}^{\mathrm{s}}$ and $\widehat{B}_{k}^{\mathrm{u}}$ have at least one common point since they are linked, while in general, $\mathscr{B}_{k}^{\mathrm{s}}$ and $\mathscr{B}_{k}^{\mathrm{u}}$ may be disjoint. See Figure 7.1 for a conceptual picture of these bridges defined on the tangency curve $L$. Finally, the pre-images of $\mathscr{B}_{k}^{\mathrm{s}, \mathrm{u}}, \widehat{B}_{k}^{\mathrm{s}, \mathrm{u}}$ and $B_{k}^{\mathrm{s}, \mathrm{u}}$ under $f^{2}$ are denoted by $\mathscr{A}_{k}^{\mathrm{s}, \mathrm{u}}, \widehat{A}_{k}^{\mathrm{s}, \mathrm{u}}$ and $A_{k}^{\mathrm{s}, \mathrm{u}}$, respectively.

Figure 7.1.
We have the following two claims.
Claim 7.3. The s-bridges $A_{k}^{\mathrm{s}}(k \in \mathbb{N})$ are uniformly pairwise disjoint.
Proof. First, let us note that $A_{k}^{\mathrm{s}}=f^{-2}\left(B_{k}^{\mathrm{s}}\right)$ for every $k$. Since $B_{k}^{\mathrm{s}}$ are obtained by Claim 6.2, they are pairwise disjoint (see Step 1 in its proof). Thus, we conclude that $A_{k}^{\mathrm{s}}(k \in \mathbb{N})$ are also pairwise disjoint. It remains to show the uniformity of the disjointness.

For every $k \in \mathbb{N}$, as $B_{k}^{\mathrm{s}} \subset L$ is an s-bridge with generation $s_{k}$, say, $B_{k}^{\mathrm{s}}=$ $B_{k}^{\mathrm{s}}\left(s_{k} ; \underline{w}^{(k)}\right)$. By (4.4) and (4.6), we see that $A_{k}^{\mathrm{s}}=A_{k}^{\mathrm{s}}\left(s_{k} ; \underline{w}^{(k)}\right) \subset \widetilde{L}$ can also be seen as the pre-image of $B r_{k}^{\mathrm{s}}=B r_{k}^{\mathrm{s}}\left(s_{k} ; \underline{w}^{(k)}\right) \subset I^{\mathrm{s}}$ under $\left.\pi_{\mathcal{F}^{\mathrm{u}}}\right|_{\widetilde{L}}$, where $\left.\pi_{\mathcal{F}^{\mathrm{u}}}\right|_{\widetilde{L}}$ is the restriction of $\pi_{\mathcal{F} u}$ to $\widetilde{L}$, see 4.2 .

Since $\left.\pi_{\mathcal{F}^{u}}\right|_{\widetilde{L}}$ is almost affine, to prove the claim, it suffices to show that $B r_{k}^{s}(k \in$ $\mathbb{N}$ ) are uniformly pairwise disjoint. Indeed, note that each $B r_{k}^{s}$ is a bridge of the Cantor set $\Lambda_{f}^{\mathrm{s}}$ defined in (4.1), we only need to show that any gap of $\Lambda_{f}^{\mathrm{s}}$ occupies a relatively large proportion in length compare to the length of its adjacent bridges. To see this, let us take an arbitrary s-gap of $\Lambda_{f}^{\mathrm{s}}$, say $G a^{\mathrm{s}}$ (recall the related definitions in Section 4.1). Suppose $B r^{\mathrm{s}}$ is either of its two adjacent bridges. By Definition 3.1 and the choice of $\theta$ in 3.13, and notice that $f$ is contained in $\mathcal{U}_{0} \subset \mathcal{U}_{F}^{r}$, we conclude that

$$
\frac{\left|B r^{\mathrm{s}}\right|}{\left|G a^{\mathrm{s}}\right|}<\theta
$$

which immediately yields

$$
\left|G a^{\mathrm{s}}\right|>\theta^{-1}\left|B r^{\mathrm{s}}\right| .
$$

Since $\theta$ (hence $\theta^{-1}$ ) is a positive constant independent of $f$, we complete the proof of the claim.

Claim 7.4. For every $k \in \mathbb{N}$ and $\underline{z}^{(k)}$ defined in 7.4, each leaf of $\mathcal{F}^{u}$ inside $\mathbb{B} r^{\mathrm{s}}\left(n_{k} ;\left[\underline{z}^{(k)}\right]^{-1}\right)$ intersects $\widetilde{L}$ transversally.

Proof. Let us fix an arbitrarily $k \in \mathbb{N}$. On the one hand, it follows from the definition of $\widehat{B}_{k+1}^{\mathrm{s}}$ in 7.2 that

$$
\widehat{B}_{k+1}^{\mathrm{s}}=\widehat{B}_{k+1}^{\mathrm{s}}\left(s_{k+1} ; \underline{\widehat{w}}^{(k+1)}\right) \subset B_{k+1}^{\mathrm{s}} \subset L
$$

Combining this fact with the definition of $\widehat{A}_{k+1}^{\mathrm{s}}$ before Claim 7.3 we have

$$
\widehat{A}_{k+1}^{\mathrm{s}}=\widehat{A}_{k+1}^{\mathrm{s}}\left(s_{k+1} ; \widehat{\widehat{w}}^{(k+1)}\right) \subset \widetilde{L}
$$

since $\widetilde{L}$ is the $f^{-2}$-image of $L$ (see Section 3.2). Therefore, by 4.3) and 4.6), each leaf of $\mathcal{F}^{\mathrm{u}}$ inside $\mathbb{B} r_{k+1}^{\mathrm{s}}\left(s_{k+1} ; \widehat{\underline{w}}^{(k+1)}\right)$ intersects $\widetilde{L}$ transversally. On the other hand, as (7.4) gives

$$
\left[\underline{z}^{(k)}\right]^{-1}=\left[\underline{\widehat{z}}^{(k)} \underline{\widehat{v}}^{(k)}\left[\underline{\widehat{w}}^{(k+1)}\right]^{-1}\right]^{-1}=\underline{\widehat{w}}^{(k+1)}\left[\underline{\widehat{v}}^{(k)}\right]^{-1}\left[\underline{\widehat{z}}^{(k)}\right]^{-1}
$$

we obtain that $\mathbb{B} r^{\mathrm{s}}\left(n_{k} ;\left[\underline{z}^{(k)}\right]^{-1}\right)$ is a sub-bridge stripe of $\mathbb{B} r_{k+1}^{\mathrm{s}}\left(s_{k+1} ; \widehat{\underline{w}}^{(k+1)}\right)$. Considering the above two aspects together, the conclusion follows immediately.
7.2. Creation of the critical chain. To give the next lemma, we need some notational preparations. Let $\mathcal{U}_{0}$ be the open set given by Claim 7.1 and $f$ an arbitrary element of $\mathcal{U}_{0}$. With the notations defined in the previous subsection, for every $k \in \mathbb{N}$, let $\widetilde{L}_{k}:=f^{n_{k}}\left(L \cap \mathbb{B} r^{u}\left(n_{k} ; \underline{z}^{(k)}\right)\right)$. As a result of Claim 7.4 we can assume that $\widetilde{L}_{k}$ intersects $\widetilde{L}$ transversely at

$$
\begin{equation*}
\boldsymbol{q}_{k} \in \mathscr{A}_{k+1}^{\mathrm{s}} \subset \widetilde{L} \tag{7.7}
\end{equation*}
$$

We also define

$$
\begin{align*}
\boldsymbol{x}_{k} & :=f^{-n_{k}}\left(\boldsymbol{q}_{k}\right) \in \mathscr{B}_{k}^{\mathrm{u}} \subset L, \quad \boldsymbol{y}_{k}:=f^{2}\left(\boldsymbol{q}_{k}\right) \in \mathscr{B}_{k+1}^{\mathrm{s}} \subset L \\
\boldsymbol{r}_{k} & :=f^{-2}\left(\boldsymbol{x}_{k}\right) \in \mathscr{A}_{k}^{\mathrm{u}} \subset \widetilde{L} \tag{7.8}
\end{align*}
$$

In other words, the following transfer sequence

$$
\boldsymbol{r}_{k} \xrightarrow{f^{2}} \boldsymbol{x}_{k} \xrightarrow{f^{n_{k}}} \boldsymbol{q}_{k} \xrightarrow{f^{2}} \boldsymbol{y}_{k}
$$

is well defined for every $k \in \mathbb{N}$. See Figure 7.2. We need to point out that all these points $\left(\boldsymbol{r}_{k}, \boldsymbol{x}_{k}, \boldsymbol{q}_{k}, \boldsymbol{y}_{k}\right)$ certainly depend on $f$.

Figure 7.2.
The main result of this section is the following so-called Critical Chain Lemma. Let us explain a little more. For every $k \in \mathbb{N}$, we have

$$
f^{n_{k}+2}\left(\boldsymbol{x}_{k}\right)=\boldsymbol{y}_{k}
$$

according to the above transfer sequence. Now, if $\boldsymbol{y}_{k}$ happens to be $\boldsymbol{x}_{k+1}$ exactly, then we are allowed to act $f^{n_{k+1}+2}$ once again on it, obtaining

$$
f^{n_{k+1}+2} \circ f^{n_{k}+2}\left(\boldsymbol{x}_{k}\right)=f^{n_{k+1}+2}\left(\boldsymbol{x}_{k+1}\right)=\boldsymbol{y}_{k+1} .
$$

Moreover, if $\boldsymbol{y}_{k}=\boldsymbol{x}_{k+1}$ holds for every $k$, we thus have the following infinite transfer sequence of $\boldsymbol{x}_{k}$, called a critical chain:

$$
\boldsymbol{x}_{1} \xrightarrow{f^{n_{1}+2}} \boldsymbol{x}_{2} \xrightarrow{f^{n_{2}+2}} \cdots \xrightarrow{f^{n_{k-2}+2}} \boldsymbol{x}_{k-1} \xrightarrow{f^{n_{k-1}+2}} \boldsymbol{x}_{k} \xrightarrow{f^{n_{k}+2}} \cdots
$$

which will be very useful when we construct the non-trivial wandering domain. However, it is quite difficult to meet such coincidental conditions for $\boldsymbol{y}_{k}$ and $\boldsymbol{x}_{k+1}$ in general. Now, we are in the position to state the following lemma which yields the desired condition.
Lemma 7.5 (Critical Chain Lemma). For every $\varepsilon>0, \widehat{m}_{k} \in \mathbb{N}$ and $\widehat{\widehat{v}}^{(k)} \in$ $\{0,1\}^{\widehat{m}_{k}}$, there exists an $\varepsilon$-small $C^{r}$ perturbation $g$ of $f$ such that, for $n_{k}, \underline{z}^{(k)}, \mathscr{B}_{k}^{\mathrm{s}}$, $\mathscr{B}_{k}^{u}, \boldsymbol{x}_{k}, \boldsymbol{y}_{k}$ defined above, for every $k=1,2, \ldots$, the followings hold:
(1) $\boldsymbol{y}_{k}=\boldsymbol{x}_{k+1}$, hence $g^{n_{k}+2}\left(\boldsymbol{x}_{k}\right)=\boldsymbol{x}_{k+1}$,
(2) $D g^{n_{k}+2}\left(T_{\boldsymbol{x}_{k}} \mathcal{F}^{\mathrm{u}}\right)=T_{\boldsymbol{x}_{k+1}} \mathcal{F}^{\mathrm{s}}$,
(3) $\widehat{u}_{k}+\widehat{s}_{k+1} \leq C k$ where $C$ is a constant independent of $k$.

Proof. For every $k \in \mathbb{N}$, we have constructed $\mathscr{B}_{k}^{\mathrm{s}}$ and $\mathscr{B}_{k}^{\mathrm{u}}$ in 7.6 . For every $k \geq 2$, recall that $\boldsymbol{y}_{k-1} \in \mathscr{B}_{k}^{\mathrm{s}} \subset \widehat{B}_{k}^{\mathrm{s}}$ and $\boldsymbol{x}_{k} \in \mathscr{B}_{k}^{\mathrm{u}} \subset \widehat{B}_{k}^{\mathrm{u}}$. Since ( $\widehat{B}_{k}^{\mathrm{s}}, \widehat{B}_{k}^{\mathrm{u}}$ ) was selected as a linked pair in (7.2), if we denote by $\left|\boldsymbol{y}_{k-1} \boldsymbol{x}_{k}\right|_{L}$ the arc-length of the segment on $L$ which connects $\boldsymbol{y}_{k-1}$ and $\boldsymbol{x}_{k}$, then we have

$$
\begin{aligned}
\left|\boldsymbol{y}_{k-1} \boldsymbol{x}_{k}\right|_{L} & \leq\left|\widehat{B}_{k}^{\mathrm{s}}\right|+\left|\widehat{B}_{k}^{\mathrm{u}}\right| \leq\left|\widehat{B}_{k}^{\mathrm{s}}\right|+\bar{\sigma}\left|\widehat{B}_{k}^{\mathrm{s}}\right| \\
& \leq(1+\bar{\sigma}) \underline{\lambda}^{k N+1} \leq 2 \underline{\lambda}^{k N},
\end{aligned}
$$

where the second and third inequalities follow from 7.3 , and the last inequality holds because $\underline{\lambda}(1+\bar{\sigma})<2$ by (5.6). Notice that

$$
\boldsymbol{q}_{k-1}=f^{-2}\left(\boldsymbol{y}_{k-1}\right) \in \mathscr{A}_{k}^{\mathrm{s}} \subset \widetilde{L} \quad \text { and } \quad \boldsymbol{r}_{k}=f^{-2}\left(\boldsymbol{x}_{k}\right) \in \mathscr{A}_{k}^{\mathrm{u}} \subset \widetilde{L}
$$

If we denote by $\boldsymbol{\zeta}_{k}=\boldsymbol{\zeta}_{k}(N)$ the vector which starts at $\boldsymbol{q}_{k-1}$ and ends at $\boldsymbol{r}_{k}$, it follows that

$$
\begin{equation*}
\left\|\zeta_{k}\right\| \leq\left|\boldsymbol{q}_{k-1} \boldsymbol{r}_{k}\right|_{\widetilde{L}} \leq C_{1} \underline{\lambda}^{k N} \tag{7.9}
\end{equation*}
$$

for some constant $C_{1}$ which only depends on the neighborhood $\mathcal{U}_{F}^{r}$.

Figure 7.3.
Denote by $\left[a_{k}, b_{k}\right]$ the projection of $A_{k}^{\mathrm{s}}$ to $\{x=0\}$ (i.e. the $y$-axis) along $\mathcal{F}^{\mathrm{u}}$. Since $A_{k}^{s}(k=1,2, \ldots)$ are uniformly pairwise disjoint by Claim 7.3, we see that [ $a_{k}, b_{k}$ ] are also $\rho$-uniformly pairwise disjoint for some $\rho>0$. We recall that $U$ is the small neighborhood of $\left(0,-a_{\mathrm{s}}\right)$ in $(-2,2)^{2}$ given in Section 3.1. Let us assume that the $\pi_{x}$-image of all points in $U$ is contained in $[-\delta, \delta]$. Let

$$
\chi(x):=\phi_{\frac{1}{4},[-\delta, \delta]}(x) \quad \text { and } \quad \chi_{k}(y):=\phi_{\frac{1}{10} \rho,\left[a_{k}, b_{k}\right]}(y)
$$

be functions defined on the $x$-axis and the $y$-axis respectively. It follows that $\chi_{k}$ ( $k=2,3, \ldots$ ) have pairwise disjoint supports. Define

$$
\Phi_{k}(\boldsymbol{x}):=\chi\left(\pi_{x}(\boldsymbol{x})\right) \cdot \chi_{k}\left(\pi_{\mathcal{F}^{u}}^{0}(\boldsymbol{x})\right)
$$

Here, $\pi_{\mathcal{F}^{u}}^{0}$ is the projection to $\{x=0\}$ along leaves of $\mathcal{F}^{u}$. According to the notations and properties of the bump function listed at the beginning of this section,
one easily deduces that

$$
\left\|\Phi_{k}\right\|_{C^{r}} \lesssim \frac{1}{\left|A_{k}^{\mathrm{s}}\right|^{r}}
$$

for every $k=2,3, \ldots$ See Figure 7.3 for the image of $\operatorname{supp}\left(\Phi_{k}\right)$.
Recall that $L$ is the tangency curve between $f^{2}\left(\mathcal{F}^{\mathrm{u}}\right)$ and $\mathcal{F}^{\mathrm{s}}$, therefore, leaves of $\mathcal{F}^{u}$ and leaves of $f^{-2} \mathcal{F}^{\mathrm{s}}$ tangent to each other along $\widetilde{L}=f^{-2}(L)$ to which $\boldsymbol{q}_{k-1}$ and $\boldsymbol{r}_{k}$ belong. If we denote by $T_{\boldsymbol{x}} \mathcal{F}^{\mathrm{s}(\mathrm{u})}$ the tangent line of the leaf of $\mathcal{F}^{\mathrm{s}(\mathrm{u})}$ passing through $\boldsymbol{x}$, then we have $T_{\boldsymbol{r}_{k}}\left(f^{-2} \mathcal{F}^{\mathrm{s}}\right)=T_{\boldsymbol{r}_{k}} \mathcal{F}^{\mathrm{u}}$. Moreover, it follows from [PT93, Appendix 1, Theorem 8] that $T_{\boldsymbol{x}} \mathcal{F}^{\mathrm{u}}$ (indeed, $T_{\boldsymbol{x}} \mathcal{F}^{\mathrm{s}}$ also) $C^{1}$-depends on $\boldsymbol{x}$. Combining these facts with 7.9 and using the mean value theorem, we see that the angle

$$
\omega_{k}:=\angle\left(T_{\boldsymbol{q}_{k-1}} \mathcal{F}^{\mathrm{u}}, T_{\boldsymbol{r}_{k}}\left(f^{-2} \mathcal{F}^{\mathrm{s}}\right)\right)=\angle\left(T_{\boldsymbol{q}_{k-1}} \mathcal{F}^{\mathrm{u}}, T_{\boldsymbol{r}_{k}} \mathcal{F}^{\mathrm{u}}\right)
$$

satisfies

$$
\begin{equation*}
\left|\omega_{k}\right| \lesssim \underline{\lambda}^{k N} . \tag{7.10}
\end{equation*}
$$

See Figure 7.4 .

Figure 7.4.

Let $D_{k}: \mathbb{R}^{2} \rightarrow \mathbb{R}^{2}$ be the rotation transformation with angle $\omega_{k}$ at $\boldsymbol{q}_{k-1}$, that is,

$$
D_{k}(\boldsymbol{x}):=\boldsymbol{q}_{k-1}+\left(\begin{array}{cc}
\cos \omega_{k} & -\sin \omega_{k} \\
\sin \omega_{k} & \cos \omega_{k}
\end{array}\right)\left(\boldsymbol{x}-\boldsymbol{q}_{k-1}\right) .
$$

Then, if $E: \mathbb{R}^{2} \rightarrow \mathbb{R}^{2}$ is the identity transformation, we have by 7.10 that

$$
\begin{equation*}
\left\|D_{k}-E\right\|_{C^{r}} \sim\left|\omega_{k}\right| \lesssim \underline{\lambda}^{k N} \tag{7.11}
\end{equation*}
$$

Consider the linear transformation $\xi_{k}$ on $\mathbb{R}^{2}$ defined by

$$
\begin{aligned}
\xi_{k}(\boldsymbol{x}): & =\boldsymbol{\zeta}_{k}+D_{k}(\boldsymbol{x})=\boldsymbol{r}_{k}-\boldsymbol{q}_{k-1}+D_{k}(\boldsymbol{x}) \\
& =\boldsymbol{r}_{k}+\left(\begin{array}{cc}
\cos \omega_{k} & -\sin \omega_{k} \\
\sin \omega_{k} & \cos \omega_{k}
\end{array}\right)\left(\boldsymbol{x}-\boldsymbol{q}_{k-1}\right)
\end{aligned}
$$

This definition immediately gives

- $\xi_{k}\left(\boldsymbol{q}_{k-1}\right)=\boldsymbol{r}_{k}$ and
- $\xi_{k}\left(\boldsymbol{q}_{k-1}\right) T_{\boldsymbol{q}_{k-1}} \mathcal{F}^{\mathrm{u}}=T_{\boldsymbol{r}_{k}}\left(f^{-2} \mathcal{F}^{\mathrm{s}}\right)$.

Moreover, we have

$$
\begin{align*}
\left\|\left.\left(\xi_{k}-\mathrm{id}\right)\right|_{U}\right\|_{C^{r}} & \leq \max _{\boldsymbol{x} \in U}\left\|\left(D_{k}(\boldsymbol{x})-\boldsymbol{x}\right)+\left(\boldsymbol{r}_{k}-\boldsymbol{q}_{k-1}\right)\right\|_{C^{r}} \\
& \leq \max _{\boldsymbol{x} \in U}\left\|D_{k}(\boldsymbol{x})-\boldsymbol{x}\right\|_{C^{r}}+\max _{\boldsymbol{x} \in U}\left\|\boldsymbol{r}_{k}-\boldsymbol{q}_{k-1}\right\|_{C^{r}}  \tag{7.12}\\
& \leq\left\|\left(\begin{array}{cc}
\cos \omega_{k} & -\sin \omega_{k} \\
\sin \omega_{k} & \cos \omega_{k}
\end{array}\right)-E\right\|_{C^{r}}+\left\|\boldsymbol{r}_{k}-\boldsymbol{q}_{k-1}\right\|_{C^{r}} \lesssim \underline{\lambda}^{k N}
\end{align*}
$$

where the last inequality comes from $(7.9)$ and $(7.11)$. Here, we recall that $U$ is the small neighborhood of $\left(0,-a_{\mathrm{s}}\right)$ in $(-2,2)^{2}$ given in Section 3.1.

Claim 7.6. There exists constant $C_{N}>0$ satisfying $C_{N} \rightarrow 0$ as $N \rightarrow \infty$, such that

$$
\sum_{k=2}^{\infty} \frac{\underline{\lambda}^{k N}}{\left|A_{k}^{\mathrm{s}}\right|^{r}} \leq C_{N}
$$

for every sufficiently large $N \in \mathbb{N}$.
Let us continue the proof of the lemma. The proof of this claim will be postponed until we finish the proof of the lemma. Let

$$
\boldsymbol{\zeta}=\boldsymbol{\zeta}(N):=\left(\boldsymbol{\zeta}_{2}, \boldsymbol{\zeta}_{3}, \ldots, \boldsymbol{\zeta}_{k}, \ldots\right)
$$

be an infinite sequence of vectors, which is called a perturbation vector sequence. We claim that the $\boldsymbol{\zeta}$-related map sequence

$$
\Phi_{\zeta, l}(\boldsymbol{x}):=\boldsymbol{x}+\sum_{k=2}^{l} \Phi_{k}(\boldsymbol{x})\left(\xi_{k}(\boldsymbol{x})-\boldsymbol{x}\right)
$$

forms a Cauchy sequence. Indeed, suppose $m$ and $n$ are any pair of positive integers with $m>n$, we thus have, by 7.12 , that

$$
\begin{aligned}
\left\|\Phi_{\zeta, m}-\Phi_{\zeta, n}\right\|_{C^{r}} & =\left\|\sum_{k=n+1}^{m} \Phi_{k}\left(\xi_{k}-\mathrm{id}\right)\right\|_{C^{r}} \leq \sum_{k=n+1}^{m}\left\|\Phi_{k}\left(\xi_{k}-\mathrm{id}\right)\right\|_{C^{r}} \\
& \lesssim \sum_{k=n+1}^{m}\left\|\Phi_{k}\right\|_{C^{r}}\left\|\left.\left(\xi_{k}-\mathrm{id}\right)\right|_{U}\right\|_{C^{r}} \lesssim \sum_{k=n+1}^{m} \frac{\lambda^{k N}}{\left|A_{k}^{\mathrm{s}}\right|^{r}}
\end{aligned}
$$

Since the series in Claim 7.6 converges, for any $\varepsilon_{0}>0$, there is a sufficiently large $N_{0} \in \mathbb{N}$ such that if $m>n>N_{0}$, we have

$$
\left\|\Phi_{\zeta, m}-\Phi_{\zeta, n}\right\|_{C^{r}}<\varepsilon_{0}
$$

As a result, we are allowed to define

$$
\Phi_{\boldsymbol{\zeta}}(\boldsymbol{x}):=\lim _{l \rightarrow \infty} \Phi_{\boldsymbol{\zeta}, l}(\boldsymbol{x})=\boldsymbol{x}+\sum_{k=2}^{\infty} \Phi_{k}(\boldsymbol{x})\left(\xi_{k}(\boldsymbol{x})-\boldsymbol{x}\right) .
$$

By definition, it is not hard to verify that $\Phi_{\zeta}$ satisfies

- $\Phi_{\boldsymbol{\zeta}}\left(\boldsymbol{q}_{k-1}\right)=\boldsymbol{r}_{k}$ and
- $\Phi_{\boldsymbol{\zeta}}\left(\boldsymbol{q}_{k-1}\right) T_{\boldsymbol{q}_{k-1}} \mathcal{F}^{\mathrm{u}}=T_{\boldsymbol{r}_{k}}\left(f^{-2} \mathcal{F}^{\mathrm{s}}\right)$
for every $k=2,3, \ldots$.
Now, let us finish the proof of Lemma 7.5. Indeed, we notice that

$$
\begin{aligned}
\operatorname{dist}_{C^{r}}\left(\Phi_{\boldsymbol{\zeta}}, \mathrm{id}\right) & =\max _{\boldsymbol{x} \in M}\left\|\sum_{k=2}^{\infty} \Phi_{k}(\boldsymbol{x})\left(\xi_{k}(\boldsymbol{x})-\boldsymbol{x}\right)\right\|_{C^{r}} \\
& \leq \sum_{k=2}^{\infty}\left\|\Phi_{k}\right\|_{C^{r}}\left\|\left.\left(\xi_{k}-\mathrm{id}\right)\right|_{U}\right\|_{C^{r}} \lesssim \sum_{k=2}^{\infty} \frac{\underline{\lambda}^{k N}}{\left|A_{k}^{s}\right|^{r}}
\end{aligned}
$$

Therefore, given an arbitrarily small $\varepsilon>0$ as in the hypothesis of Lemma 7.5 , according to Claim 7.6 with a sufficiently large $N$, it holds that $\operatorname{dist}_{C^{r}}\left(\Phi_{\zeta}\right.$, id $)<$ $\varepsilon\|f\|_{C^{r}}^{-1}$. Define

$$
g:=f \circ \Phi_{\zeta}: M \rightarrow M
$$

Then, we have

$$
\operatorname{dist}_{C^{r}}(g, f) \leq \operatorname{dist}_{C^{r}}\left(\Phi_{\zeta}, \mathrm{id}\right)\|f\|_{C^{r}}<\varepsilon
$$

In other words, we see that $g$ is an $\varepsilon$-small $C^{r}$-perturbation of $f$. Since $\operatorname{Diff}^{r}(M)$ is open in the space of $C^{r}$ self-maps of $M$, we conclude that $g$ is also an element of Diff $^{r}(M)$.

It remains to verify that $g$ satisfies the conclusion of Lemma 7.5 . For (1), we have

$$
\begin{aligned}
g^{n_{k-1}+2}\left(\boldsymbol{x}_{k-1}\right) & =\left(f \circ \Phi_{\boldsymbol{\zeta}}\right)^{2} \circ\left(f \circ \Phi_{\boldsymbol{\zeta}}\right)^{n_{k-1}}\left(\boldsymbol{x}_{k-1}\right) \\
& =\left(f \circ \Phi_{\boldsymbol{\zeta}}\right)^{2} \circ f^{n_{k-1}}\left(\boldsymbol{x}_{k-1}\right)=\left(f \circ \Phi_{\boldsymbol{\zeta}}\right)^{2}\left(\boldsymbol{q}_{k-1}\right) \\
& =f \circ \Phi_{\boldsymbol{\zeta}} \circ f\left(\boldsymbol{r}_{k}\right)=f^{2}\left(\boldsymbol{r}_{k}\right)=\boldsymbol{x}_{k} .
\end{aligned}
$$

For (2), we have

$$
\begin{aligned}
D g^{n_{k-1}+2}\left(\boldsymbol{x}_{k-1}\right) T_{\boldsymbol{x}_{k-1}} \mathcal{F}^{\mathrm{u}} & =D g^{2}\left(\boldsymbol{q}_{k-1}\right) T_{\boldsymbol{q}_{k-1}} \mathcal{F}^{\mathrm{u}} \\
& =D\left(f \circ \Phi_{\boldsymbol{\zeta}} \circ f\right)\left(\boldsymbol{r}_{k}\right) T_{\boldsymbol{r}_{k}}\left(f^{-2} \mathcal{F}^{\mathrm{s}}\right)=T_{\boldsymbol{x}_{k}} \mathcal{F}^{\mathrm{s}}
\end{aligned}
$$

For (3), note that we have

$$
\underline{\lambda}^{(k+1) N} \lesssim\left|B_{k+1}^{\mathrm{s}}\left(\widehat{s}_{k+1} ; \underline{w}^{(k+1)}\right)\right| \lesssim \bar{\lambda}^{\widehat{s}_{k+1}}
$$

where the first inequality comes from $(7.3)$ and the second inequality comes from (4.9).

Thus, one can suppose that

$$
\widehat{s}_{k+1} \leq k N \frac{\log \underline{\lambda}}{\log \bar{\lambda}}
$$

if necessary replacing $N$ by a larger integer. Similarly, we can also deduce that

$$
\widehat{u}_{k} \leq k N \frac{\log \underline{\lambda}}{\log \underline{\sigma}^{-1}}
$$

Therefore, if we take

$$
C>\max \left\{\frac{N \log \underline{\lambda}}{\log \bar{\lambda}}, \frac{N \log \underline{\lambda}}{\log \underline{\sigma}^{-1}}\right\}
$$

large enough, then $\widehat{s}_{k+1}+\widehat{u}_{k}<C k$ holds for every $k$. We now complete the proof of Lemma 7.5 ,

Proof of Claim 7.6. Indeed, recall that the sequence $B_{k}^{\mathrm{s}}$ is obtained from Lemma 6.1 with generations $s_{k}$ satisfying $s_{k} \leq s_{0}+k N_{\mathrm{s}}$ for some $s_{0}$. Thus, for every $k=2,3, \ldots$, we have

$$
\left|A_{k}^{\mathrm{s}}\right| \sim\left|B_{k}^{\mathrm{s}}\right| \gtrsim \underline{\lambda}^{s_{k}} \gtrsim \underline{\lambda}^{k N_{\mathrm{s}}},
$$

which implies that, if $N>r N_{\mathrm{s}}$, then there is some constant $C^{\prime}>0$ independent of $k$ such that

$$
\begin{aligned}
\sum_{k=2}^{\infty} \frac{\underline{\lambda}^{k N}}{\left|A_{k}^{\mathrm{s}}\right|^{r}} & \leq C^{\prime} \sum_{k=2}^{\infty} \frac{\underline{\lambda}^{k N}}{\underline{\lambda}^{k r N_{s}}}=C^{\prime} \sum_{k=2}^{\infty} \underline{\lambda}^{k\left(N-r N_{\mathrm{s}}\right)} \\
& =\frac{C^{\prime} \underline{\lambda}^{2\left(N-r N_{\mathrm{s}}\right)}}{1-\underline{\lambda}^{N-r N_{\mathrm{s}}}}=: C_{N}
\end{aligned}
$$

Thus we finish the proof of the Claim 7.6 by noticing $C_{N} \rightarrow 0$ as $N \rightarrow \infty$.

## 8. Rectangle Lemma

In this section, we will construct a sequence of rectangles. Each rectangle in this sequence is located around $\boldsymbol{x}_{k}$ of the critical chain obtained in the previous section. It will be the non-trivial wandering domain that we aim to construct. To this end, let us begin with some preliminary work.

Choose an arbitrary element $f$ of $\mathcal{U}_{0}$. With the notations defined in the previous section, let us take

$$
\begin{equation*}
\widehat{m}_{k}=k^{2} \tag{8.1}
\end{equation*}
$$

in Lemma 7.5 Since $\widehat{s}_{k+1}+\widehat{u}_{k}<C k$ for some constant $C>0$ independent of $k$ as indicated in Lemma 7.5 (3), it is not hard to see that $n_{k}$ defined in (7.5) is increasing and

$$
\frac{\widehat{u}_{k}+\widehat{s}_{k+1}}{\widehat{m}_{k}}=\frac{O(k)}{k^{2}} \rightarrow 0
$$

as $k \rightarrow \infty$. Moreover, since

$$
\frac{n_{k+1}}{n_{k}}=\frac{(k+1)^{2}+O(k+1)}{k^{2}+O(k)} \rightarrow 1
$$

as $k \rightarrow \infty$, for every $\eta>0$, it holds that

$$
\begin{equation*}
n_{k+1}<(1+\eta) n_{k} \tag{8.2}
\end{equation*}
$$

for every sufficiently large $k$. Let us assume that this inequality holds for every $k \in \mathbb{N}$ for notation simplicity (otherwise it is enough to translate the subscript). In addition, we can require that $\eta>0$ is so small that

$$
\begin{equation*}
\bar{\lambda} \bar{\sigma} \bar{\sigma}^{\frac{1+2 \eta}{1-\eta}}<1 \tag{8.3}
\end{equation*}
$$

holds by $\bar{\lambda} \bar{\sigma}<1$, see (3.1).
Lemma 8.1 (Rectangle Lemma). For every $f \in \mathcal{U}_{0}$, there exist an arbitrarily small $C^{r}$ perturbation $g$ of $f$ and a sequence of (topological) rectangles $R_{k}(k=1,2, \ldots)$ such that each $R_{k}$ has $\boldsymbol{x}_{k}$ as its center and satisfies the following properties:
(1) $\operatorname{diam}\left(R_{k}\right) \rightarrow 0$ as $k \rightarrow \infty$,
(2) for the rectangle $Q=[-1,1]^{2}$,

$$
R_{k} \subset \mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right) \cap\left(Q \backslash\left(g\left(S_{0, g}\right) \cup g\left(S_{1, g}\right)\right)\right),
$$

in particular, $\left\{R_{k}\right\}$ are pairwise disjoint,
(3) $g^{n_{k}+2}\left(R_{k}\right) \subset R_{k+1}$.

Proof. Let $\widehat{m}_{k}$ be selected as in 8.1. Fix an arbitrarily small $\varepsilon>0$. By applying Lemma 6.1 and Lemma 7.5 to $f$ sequentially, we obtain $g$ which satisfies, in particular, items (1) and (2) of Lemma 7.5. By shrinking $\varepsilon$ in advance if necessary, we can require the $C^{r}$-distance between $g$ and $f$ to be as small as we want. As a result, for every $(x, y) \in U$, we can write

$$
\begin{equation*}
g^{2}(x, y)=\left(-\tilde{a}_{\mathrm{u}}+\tilde{\mu}-\tilde{\beta} x^{2}-\tilde{\gamma}\left(y+\tilde{a}_{\mathrm{s}}\right),-\tilde{\alpha} x\right)+h(x, y) \tag{8.4}
\end{equation*}
$$

where all of the coefficients $\tilde{\alpha}, \tilde{\beta}, \tilde{\gamma}, \tilde{\mu}, \tilde{a}_{\mathrm{u}}, \tilde{a}_{\mathrm{s}}$ are $\varepsilon$-close to $\alpha, \beta, \gamma, \mu, a_{\mathrm{u}}, a_{\mathrm{s}}$ respectively, and $h(x, y)$ is the higher order terms containing $o\left(x^{2}\right)$ and $o(y)$.

Let $\rho \in(0,1)$ be a constant which will be fixed later, and define

$$
\begin{equation*}
b_{k}:=\rho \tilde{\beta}^{-1} \bar{\sigma}^{-\sum_{i=0}^{\infty} \frac{n_{k+i}}{2^{i}} .} \tag{8.5}
\end{equation*}
$$

It follows immediately from

$$
2 n_{k}=\sum_{i=0}^{\infty} \frac{n_{k}}{2^{i}} \leq \sum_{i=0}^{\infty} \frac{n_{k+i}}{2^{i}} \leq n_{k} \sum_{i=0}^{\infty}\left(\frac{1+\eta}{2}\right)^{i}=\frac{2 n_{k}}{1-\eta}
$$

that

$$
\begin{equation*}
\rho \tilde{\beta}^{-1} \bar{\sigma}^{-\frac{2}{1-\eta} n_{k}} \leq b_{k} \leq \rho \tilde{\beta}^{-1} \bar{\sigma}^{-2 n_{k}} \tag{8.6}
\end{equation*}
$$

The desired rectangle $R_{k}$ will be defined by taking leaves of $\mathcal{F}^{\mathrm{s}}$ and $\mathcal{F}^{\mathrm{u}}$ as its boundary. Let us be more precise. Denote by $\mathcal{F}^{\mathrm{s}(\mathrm{u})}(\boldsymbol{x})$ the leaf of $\mathcal{F}^{\mathrm{s}(\mathrm{u})}$ passing through $\boldsymbol{x}$. Take $\boldsymbol{x}_{k}^{l}, \boldsymbol{x}_{k}^{r} \in \mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}\right)$ and $\boldsymbol{x}_{k}^{t}, \boldsymbol{x}_{k}^{b} \in \mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}\right)$ with

$$
\begin{align*}
\left|\boldsymbol{x}_{k}^{l} \boldsymbol{x}_{k}\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}\right)} & =\left|\boldsymbol{x}_{k} \boldsymbol{x}_{k}^{r}\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}\right)}=b_{k} / 2,  \tag{8.7}\\
\left|\boldsymbol{x}_{k}^{t} \boldsymbol{x}_{k}\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}\right)} & =\left|\boldsymbol{x}_{k} \boldsymbol{x}_{k}^{b}\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}\right)}=10 \tilde{\alpha} \tilde{\beta}^{-\frac{1}{2}} \sqrt{b_{k}} \tag{8.8}
\end{align*}
$$

Thus, the four leaves $\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}^{t}\right), \mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}^{b}\right), \mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}^{l}\right)$ and $\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}^{r}\right)$ bound a rectangle $R_{k}$ whose top, bottom, left and right boundaries are sub-arcs of these leaves centered at $\boldsymbol{x}_{k}^{t}, \boldsymbol{x}_{k}^{b}, \boldsymbol{x}_{k}^{l}$ and $\boldsymbol{x}_{k}^{r}$, respectively. Briefly, we call $b_{k}$ and $20 \tilde{\alpha} \tilde{\beta}^{-\frac{1}{2}} \sqrt{b_{k}}$ the width and height of $R_{k}$. See Figure 8.1 .

Now, it remains to verify that $R_{k}$ satisfies the conclusions (1)-(3).
For (1), notice that

$$
\operatorname{diam}\left(R_{k}\right) \lesssim \max \left\{\left|\boldsymbol{x}_{k}^{l} \boldsymbol{x}_{k}\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}\right)},\left|\boldsymbol{x}_{k} \boldsymbol{x}_{k}^{r}\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}\right)},\left|\boldsymbol{x}_{k}^{t} \boldsymbol{x}_{k}\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}\right)},\left|\boldsymbol{x}_{k} \boldsymbol{x}_{k}^{b}\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}\right)}\right\} .
$$

Hence, (1) is an immediate consequence of 8.7) and 8.8 together with the fact that $b_{k} \rightarrow 0$ as $k \rightarrow \infty$.

For (2), first, let us note that by $\sqrt{7.7}$ ) and $(7.8)$, we have

$$
\begin{equation*}
\boldsymbol{x}_{k} \in G_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right) \tag{8.9}
\end{equation*}
$$

for every $k$. Here, we recall that $G_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$ is the u-gap of generation $n_{k}$ and itinerary $\underline{z}^{(k)}$ on the tangency curve $L_{g}$, see the end of Section 4.1. Since gap strips with different itineraries are pairwise disjoint, to show the pairwise disjointness of $R_{k}$, it is sufficient to prove that each $R_{k}$ is completely contained in the middle component of

$$
\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right) \cap\left(Q \backslash\left(g\left(S_{0, g}\right) \cup g\left(S_{1, g}\right)\right)\right)
$$

Figure 8.1.
where $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$ is the gap strip associated to $G a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$ and $S_{0, g}, S_{1, g}$ are the continuations of $S_{0}, S_{1}$ for $g$ which is defined in Section 3.1. To see this, notice that both the width of $R_{k}$ and the width of $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$ tend to zero as $k$ goes to infinity, we need to prove the followings hold:
(i) the width comparison (i.e. the ratio of widths of $R_{k}$ and $\left.G_{k}^{u}\left(n_{k} ; \underline{z}^{(k)}\right)\right)$ tends to zero as $k \rightarrow \infty$, and
(ii) the center $\boldsymbol{x}_{k}$ of $R_{k}$ is always located at the relative center position of $G_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$ for every $k=1,2, \ldots$,
which together imply that, the left and right boundaries of $R_{k}$ do not exceed the boundaries of $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$. In other words, the entire rectangle $R_{k}$ is wholly contained in $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$.

Indeed, combining $\sqrt{8.9}$ and 8.6 , we have

$$
\frac{\operatorname{width}\left(R_{k}\right)}{\left|G_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)\right|} \lesssim \frac{\left|\boldsymbol{x}_{k}^{l} \boldsymbol{x}_{k}\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}\right)}}{\bar{\sigma}^{-n_{k}}}=\frac{1}{2} \rho \tilde{\beta}^{-1} \bar{\sigma}^{-n_{k}} \rightarrow 0 \quad(k \rightarrow \infty)
$$

where the inequality comes from (8.6) and 8.7). This gives (i). For (ii), let us note that for $\varepsilon_{0}$ is defined in Section 3.2 , the minimum distance between points on $\widetilde{L}$ and the vertical strips $S_{0, g} \cup S_{1, g}$ is greater than $\left(\frac{1}{2}-\sigma^{-1}-\varepsilon_{0}\right)$. In particular, the distance between $\boldsymbol{q}_{k}$ and the boundary of the center gap strip of $I_{g}^{\mathrm{u}}$ is bounded from below by this number. Here, we recall that $I_{g}^{\mathrm{u}}$ is the continuation of $I^{\mathrm{u}}$ for $g$ defined in Section 4.1. Thus, by the action of the backward iteration $g^{-n_{k}}$, recalling that $\boldsymbol{x}_{k}$ is the pre-image of $\boldsymbol{q}_{k} \in \widetilde{L}$ under $g^{n_{k}}$, the distance of $\boldsymbol{x}_{k}$ and the the boundary of $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$ is greater than $\bar{\sigma}^{-n_{k}}\left(\frac{1}{2}-\sigma^{-1}-\varepsilon_{0}\right)$. On the other hand, by (8.6), the width $b_{k}$ of $R_{k}$ is no more than $\rho \tilde{\beta}^{-1} \bar{\sigma}^{-2 n_{k}}=O\left(\bar{\sigma}^{-2 n_{k}}\right)$. Hence (ii) holds for every sufficiently large $k$. It follows that

$$
R_{k} \subset \mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right) \cap\left(Q \backslash\left(g\left(S_{0, g}\right) \cup g\left(S_{1, g}\right)\right)\right)
$$

as desired in (2).
For (3), let $\ell_{k}^{u}$ be the segment of $\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k}\right)$ that connects $\boldsymbol{x}_{k}^{l}$ and $\boldsymbol{x}_{k}^{r}$ and $\ell_{k}^{\mathrm{s}}$ the segment of $\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k}\right)$ that connects $\boldsymbol{x}_{k}^{t}$ and $\boldsymbol{x}_{k}^{b}$. We use

$$
\pi_{\mathcal{F}^{\mathrm{u}}}^{*}: R_{k} \rightarrow \ell_{k}^{\mathrm{s}} \quad \text { and } \quad \pi_{\mathcal{F}^{\mathrm{s}}}^{*}: R_{k} \rightarrow \ell_{k}^{\mathrm{u}}
$$

to denote the projections along the leaves of $\mathcal{F}^{\mathrm{u}}$ and $\mathcal{F}^{\mathrm{s}}$ to $\ell_{k}^{\mathrm{s}}$ and $\ell_{k}^{\mathrm{u}}$ respectively. First, Let us show that $g^{n_{k}+2}\left(\ell_{k}^{u}\right) \subset \frac{1}{2} R_{k+1}$, where $\frac{1}{2} R_{k}$ is the rectangle defined in the same way as $R_{k}$ but replacing its width and height by half of those of $R_{k}$ 's. See Figure 8.1. Indeed, on the one hand, we have

$$
\begin{align*}
\left|\pi_{\mathcal{F}^{\mathrm{u}}}^{*}\left(g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right)\right)\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k+1}\right)} & \lesssim\left|g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right)\right| \lesssim \tilde{\alpha}\left|g^{n_{k}}\left(\ell_{k}^{\mathrm{u}}\right)\right| \leq \tilde{\alpha} \bar{\sigma}^{n_{k}} b_{k} \\
& =\rho \tilde{\alpha} \tilde{\beta}^{-1} \bar{\sigma}^{-\sum_{i=1}^{\infty} \frac{n_{k+i}}{2^{i}}}=\sqrt{\rho} \tilde{\alpha} \tilde{\beta}^{-\frac{1}{2}} \sqrt{b_{k+1}} . \tag{8.10}
\end{align*}
$$

Thus, by taking $\rho>0$ sufficiently small in (8.5), we have

$$
\begin{equation*}
\left|\pi_{\mathcal{F}^{\mathrm{u}}}^{*}\left(g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right)\right)\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k+1}\right)}<10 \tilde{\alpha} \tilde{\beta}^{-\frac{1}{2}} \sqrt{b_{k+1}}=\frac{1}{2}\left|\boldsymbol{x}_{k+1}^{t} \boldsymbol{x}_{k+1}^{b}\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k+1}\right)} \tag{8.11}
\end{equation*}
$$

On the other hand, by [PT93, Theorem 8 in Appendix 1], the curvature of the leaves $\mathcal{F}^{\mathrm{s}}(\boldsymbol{x})$ and $\mathcal{F}^{\mathrm{u}}(\boldsymbol{x})$ depend continuously on $\boldsymbol{x}$. Since the tangency between $g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right)$ and $\ell_{k+1}^{\mathrm{s}}$ is quadratic, there is a constant $C$ independent of $k$, such that

$$
\begin{aligned}
\left|\pi_{\mathcal{F}^{\mathrm{s}}}^{*}\left(g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right)\right)\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k+1}\right)} & \leq C\left|\pi_{\mathcal{F}^{\mathrm{u}}}^{*}\left(g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right)\right)\right|_{\mathcal{F}^{\mathrm{s}}\left(\boldsymbol{x}_{k+1}\right)}^{2} \\
& \lesssim\left(\tilde{\alpha} \rho \tilde{\beta}^{-1}\right)^{2} \bar{\sigma}^{-\sum_{i=0}^{\infty} \frac{n_{k+1+i}}{2^{i}}},
\end{aligned}
$$

where the last line follows from 8.10 and 8.5. Notice that by shrinking $\rho$ if necessary,

$$
\left(\tilde{\alpha} \rho \tilde{\beta}^{-1}\right)^{2} \bar{\sigma}^{-\sum_{i=0}^{\infty} \frac{n_{k+1+i}}{2^{i}}}=O\left(\rho^{2}\right)
$$

can be made much smaller than

$$
\frac{1}{2} b_{k+1}=\frac{1}{2} \rho \tilde{\beta}^{-1} \bar{\sigma}^{-\sum_{i=0}^{\infty} \frac{n_{k+1+i}}{2^{i}}},
$$

so that the following inequality

$$
\begin{equation*}
\left|\pi_{\mathcal{F}^{\mathrm{s}}}^{*}\left(g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right)\right)\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k+1}\right)}<\frac{1}{2} b_{k+1}=\frac{1}{2}\left|\boldsymbol{x}_{k+1}^{l} \boldsymbol{x}_{k+1}^{r}\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k+1}\right)} \tag{8.12}
\end{equation*}
$$

holds. Then 8.11) and 8.12 together imply that $g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right) \subset \frac{1}{2} R_{k+1}$.
Now, let us continue to show that $g^{n_{k}+2}\left(R_{k}\right) \subset R_{k+1}$. For every $\boldsymbol{x} \in \ell_{k}^{\mathrm{u}}$, write $\ell_{k}^{\mathrm{s}}(\boldsymbol{x}):=\mathcal{F}_{k}^{\mathrm{s}}(\boldsymbol{x}) \cap R_{k}$. Thus, on the one hand, we have

$$
\begin{align*}
\left|g^{n_{k}+2}\left(\ell_{k}^{\mathrm{s}}(\boldsymbol{x})\right)\right| & \lesssim \tilde{\gamma}\left|g^{n_{k}}\left(\ell_{k}^{\mathrm{s}}(\boldsymbol{x})\right)\right| \leq \tilde{\gamma} \bar{\lambda}^{n_{k}}\left|\ell_{k}^{\mathrm{s}}(\boldsymbol{x})\right| \\
& \leq 20 \tilde{\alpha} \tilde{\beta}^{-\frac{1}{2}} \tilde{\gamma} \bar{\lambda}^{n_{k}} \sqrt{b_{k}}=20 \tilde{\alpha} \tilde{\beta}^{-1} \tilde{\gamma} \sqrt{\rho} \bar{\lambda}^{n_{k}} \bar{\sigma}^{-\sum_{i=0}^{\infty} \frac{n_{k+i}}{2^{i+1}}} . \tag{8.13}
\end{align*}
$$

On the other hand, 8.7) gives

$$
\begin{equation*}
\left|\boldsymbol{x}_{k+1}^{l} \boldsymbol{x}_{k+1}\right|_{\mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k+1}\right)}=\frac{1}{2} b_{k+1}=\frac{1}{2} \rho \tilde{\beta}^{-1} \bar{\sigma}^{-\sum_{i=0}^{\infty} \frac{n_{k+1+i}}{2^{i}}} \tag{8.14}
\end{equation*}
$$

Hence, by recalling (8.3), it follows from (8.13) and 8.14 that we have the following width comparison

$$
\begin{aligned}
\frac{\left|g^{n_{k}+2}\left(\ell_{k}^{\mathrm{s}}(\boldsymbol{x})\right)\right|}{\left|\boldsymbol{x}_{k+1}^{l} \boldsymbol{x}_{k+1}\right| \mathcal{F}^{\mathrm{u}}\left(\boldsymbol{x}_{k+1}\right)} & \lesssim \frac{40 \tilde{\alpha} \tilde{\gamma}}{\sqrt{\rho}} \bar{\lambda}^{n_{k}} \bar{\sigma}^{\sum_{i=0}^{\infty} \frac{n_{k+1+i}}{2^{i}}-\sum_{i=0}^{\infty} \frac{n_{k+i}}{2^{i+1}}} \\
& \leq \frac{40 \tilde{\alpha} \tilde{\gamma}}{\sqrt{\rho}}\left(\bar{\lambda} \bar{\sigma}^{\frac{1+2 \eta}{1-\eta}}\right)^{n_{k}} \rightarrow 0 \quad(k \rightarrow \infty)
\end{aligned}
$$

where the last inequality is obtained by a direct calculation together with (8.2). Thus, when $\boldsymbol{x}$ travels along $\ell_{k}^{\mathrm{u}}$, we see that $g^{n_{k}+2}\left(\ell_{k}^{\mathrm{s}}(\boldsymbol{x})\right)$ can cover every point of $g^{n_{k}+2}\left(R_{k}\right)$. Therefore, the width comparison and the fact that $g^{n_{k}+2}\left(\ell_{k}^{\mathrm{u}}\right) \subset \frac{1}{2} R_{k+1}$ together imply that $g^{n_{k}+2}\left(R_{k}\right) \subset R_{k+1}$ holds for every sufficiently large $k$. Finally, by translating the subscript (i.e. rename $R_{k}, R_{k+1}, R_{k+2}, \ldots$ by $R_{1}, R_{2}, R_{3}, \ldots$ ) if necessary, we proved (3), which also completes the proof of Lemma 8.1.

## 9. Proofs of main results

In the following proof, we identify certain combinatorial conditions, from which we derive the statistical conclusion of the first main result.

Proof of Theorem $A$, Let $F_{0}$ be the diffeomorphism with the wild Smale horseshoe $\Lambda_{F_{0}}$ given in Section 7, and let $x$ be any element of $\Lambda_{F_{0}}$. Suppose that $\mathbb{U}_{0}, \mathbb{U}_{1}$ are small open regular neighborhoods of the rectangles $S_{0}, S_{1}$ in $M$ given in Section 3.1 respectively. For the coding map $h: \Lambda_{F_{0}} \longrightarrow\{0,1\}^{\mathbb{Z}}$ with respect to $\left\{\mathbb{U}_{0}, \mathbb{U}_{1}\right\}$, we set

$$
\begin{equation*}
h(x)=\underline{v}=\left(\ldots v_{-2} v_{-1} v_{0} v_{1} v_{2} \ldots\right) . \tag{9.1}
\end{equation*}
$$

For any $f \in \mathcal{U}_{0}$, we have a $C^{r}$ diffeomorphism $g \in \mathcal{U}_{0}$ with the following conditions: $g$ is arbitrarily $C^{r}$-close to $f$ and $g$ has a topological rectangle $R_{k}$ satisfying the conditions (1)-(3) of Lemma 8.1. In particular, by Lemma 8.1 (2), for any given integer $k \geq 1, R_{k}$ is contained in the gap strip $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$, where generation and itinerary are given by 7.4 and 7.5 as

$$
n_{k}=\widehat{u}_{k}+\widehat{m}_{k}+\widehat{s}_{k+1}, \quad \underline{z}^{(k)}=\underline{\widehat{z}}^{(k)} \underline{\widehat{v}}^{(k)}\left[\underline{\widehat{w}}^{(k+1)}\right]^{-1}
$$

Here we consider the integer interval $\mathbb{I}_{k}=\left[\alpha_{k}, \alpha_{k}+\beta_{k}\right] \cap \mathbb{Z}$ with

$$
\alpha_{k}=\sum_{i=0}^{k-1}\left(n_{i}+2\right)+\widehat{u}_{k}, \quad \beta_{k}=\widehat{m}_{k},
$$

and $n_{i}=\widehat{u}_{i}+\widehat{m}_{i}+\widehat{s}_{i+1}$ is the generation of the itinerary $\underline{z}^{(i)}$ given in 7.5 . See Figure 9.1. Then one can take the middle part $\widehat{\widehat{v}}^{(k)}$ has the form

Figure 9.1.

$$
\begin{equation*}
\underline{\widehat{v}}^{(k)}=\left(v_{\alpha_{k}+1} v_{\alpha_{k}+2} \ldots v_{\alpha_{k}+\beta_{k}}\right) . \tag{9.2}
\end{equation*}
$$

For any $q \in \mathbb{N}$, we set $\mathbb{I}_{k}^{(q)}=\left[\alpha_{k}+q, \alpha_{k}+\beta_{k}-q\right] \cap \mathbb{Z}$ if $2 q \leq \beta_{k}$ and otherwise $\mathbb{I}_{k}^{(q)}=\emptyset$.

For any integer $N \geq \alpha_{1}+\beta_{1}+1$, let $k_{N}$ be the greatest integer with $\alpha_{k_{N}}+\beta_{k_{N}} \leq$ $N-1$. It follows from Lemma 7.5 (3) and (8.1) that, for any $\varepsilon>0$ and $q \in \mathbb{N}$, there exists an integer $N_{0}=N_{0}(\varepsilon, q)>0$ such that, for any $N \geq N_{0}$,

$$
\begin{aligned}
& \frac{\#\left\{0 \leq n \leq N-1: n \in \bigcup_{k=1}^{\infty} \mathbb{I}_{k}^{(q)}\right\}}{N} \geq \frac{\sum_{k=1}^{k_{N}}\left(\widehat{m}_{k}-2 q\right)}{\sum_{k=1}^{k_{N}+1}\left(\widehat{u}_{k}+\widehat{m}_{k}+\widehat{s}_{k+1}+2\right)} \\
&=\frac{\sum_{k=1}^{k_{N}} k^{2}-2 q k_{N}}{\sum_{k=1}^{k_{N}+1}\left(k^{2}+O(k)\right)+2\left(k_{N}+1\right)}=\frac{2 k_{N}^{3} / 6+O\left(k_{N}^{2}\right)}{2 k_{N}^{3} / 6+O\left(k_{N}^{2}\right)}>1-\varepsilon
\end{aligned}
$$

This implies that

$$
\begin{equation*}
\#\left\{[0, N-1] \cap \mathbb{Z} \backslash \bigcup_{k=1}^{\infty} \mathbb{I}_{k}^{(q)}\right\}<N \varepsilon \quad \text { if } \quad N \geq N_{0} \tag{9.3}
\end{equation*}
$$

We set $\operatorname{Int}\left(R_{1}\right)=D$. By Lemma 8.1 (2) and (9.2),

$$
\begin{equation*}
g^{n}(D) \subset g^{n}\left(R_{1}\right) \subset \mathbb{U}_{v_{n}} \tag{9.4}
\end{equation*}
$$

if $n \in \bigcup_{k \in \mathbb{N}}\left(\mathbb{I}_{k} \backslash\left\{\alpha_{k}\right\}\right)$.
Since $g$ is sufficiently $C^{r}$ close to $f$ and hence to $F$ if $\mathcal{U}_{0}$ is sufficiently close to $F$ (see Remark 7.2 , one can suppose that $\bigcap_{i \in \mathbb{Z}} g^{i}\left(\mathbb{U}_{0} \sqcup \mathbb{U}_{1}\right)$ is equal to the continuation $\Lambda_{g}$ of $\Lambda$. Then there exists an integer $N_{1}>0$ such that, for any integer $k>0$ with $k^{2}>2 N_{1}$ and any $j \in \mathbb{I}_{k}^{\left(N_{1}\right)}$,

$$
\operatorname{diam}\left(\bigcap_{i \in\left(\mathbb{I}_{k} \backslash\left\{\alpha_{k}\right\}\right)} g^{j-i}\left(\mathbb{U}_{v_{i}}\right)\right) \leq \operatorname{diam}\left(\bigcap_{u=-N_{1}}^{N_{1}} g^{-u}\left(\mathbb{U}_{v_{j+u}}\right)\right)<\varepsilon
$$

By (9.4), $g^{j}(D) \subset \bigcap_{i \in\left(\mathbb{I}_{k} \backslash\left\{\alpha_{k}\right\}\right)} g^{j-i}\left(\mathbb{U}_{v_{i}}\right)$. By 9.1), the continuation $x_{g} \in \Lambda_{g}$ of $x$ satisfies $\left\{x_{g}\right\}=\bigcap_{i \in \mathbb{Z}} g^{-i}\left(\mathbb{U}_{v_{i}}\right)$ and hence $g^{j}\left(x_{g}\right) \in \bigcap_{i \in\left(\mathbb{I}_{k} \backslash\left\{\alpha_{k}\right\}\right)} g^{j-i}\left(\mathbb{U}_{v_{i}}\right)$. Thus we have

$$
\sup _{y \in D} \operatorname{dist}\left(g^{j}(y), g^{j}\left(x_{g}\right)\right) \leq \varepsilon
$$

for any $j \in \mathbb{I}_{k}^{\left(N_{1}\right)}$. By this fact together with 9.3 for $q=N_{1}$,

$$
\begin{aligned}
& \sum_{j=0}^{N-1} \sup _{y \in D} \operatorname{dist}\left(g^{j}(y), g^{j}\left(x_{g}\right)\right)= \sum_{j \in \bigcup_{k=1}^{\infty} \mathbb{I}_{k}^{\left(N_{1}\right)} \cap[0, N-1]} \sup _{y \in D} \operatorname{dist}\left(g^{j}(y), g^{j}\left(x_{g}\right)\right) \\
&+\sum_{j \in[0, N-1] \cap \mathbb{Z} \backslash \bigcup_{k=1}^{\infty} \mathbb{I}_{k}^{\left(N_{1}\right)}} \sup _{y \in D} \operatorname{dist}\left(g^{j}(y), g^{j}\left(x_{g}\right)\right) \\
&<N \varepsilon+N \varepsilon \operatorname{diam}(M)=N \varepsilon(1+\operatorname{diam}(M))
\end{aligned}
$$

for any sufficiently large $N \in \mathbb{N}$. Since one can take $\varepsilon$ arbitrarily small, the equation (2.2) holds. This ends the proof of Theorem A.

Next, Theorem B follows immediately from the next result.
Proposition 9.1. Suppose that $\mathcal{U}_{0}$ is the $C^{r}$-neighborhood of $F_{0}$ with the wild horseshoe $\Lambda_{F_{0}}$ in Theorem $\boxed{A}$. Then, for any $f \in \mathcal{U}_{0}$, the following conditions hold.
(1) For every Birkhoff regular $x \in \Lambda_{F_{0}}$ of $F_{0}$, there is a diffeomorphism $g \in \mathcal{U}_{0}$ which is arbitrarily $C^{r}$-close to $f$ and has a non-trivial physical measure supported on the forward $g$-orbit of the continuation $x_{g} \in \Lambda_{g}$ of $x$.
(2) There is a diffeomorphism $g \in \mathcal{U}_{0}$ which is arbitrarily $C^{r}$-close to $f$ and has a non-trivial contracting wandering domain $D$ such that the forward orbit of any point in $D$ has historic behavior.

Proof (including the proof of Theorem B). First, we give the proof of (1). Let $g$ be the diffeomorphism obtained in Lemma 8.1 and $\Lambda_{g}$ the wild horseshoe for $g$. The continuation $x_{g} \in \Lambda_{g}$ is Birkhoff regular . Let

$$
h\left(x_{g}\right)=\left(\ldots v_{-2} v_{-1} v_{0} v_{1} v_{2} \ldots\right) \in\{0,1\}^{\mathbb{Z}}
$$

be the code of $x_{g}$, where $h: \Lambda_{g} \longrightarrow\{0,1\}^{\mathbb{Z}}$ is the coding map given by $g^{i}\left(x_{g}\right) \in$ $\mathbb{U}_{v_{i}}$. Same as the proof of Theorem A, we here consider the itinerary $\underline{z}^{(k)}=$ $\underline{\widehat{z}}^{(k)} \widehat{\widehat{v}}^{(k)}\left[\underline{\widehat{w}}^{(k+1)}\right]^{-1}$ of the gap strip $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$ containing $R_{k}$. Since one can choose any element of $\{0,1\}^{k^{2}}$ as the middle part $\underline{\widehat{v}}^{(k)}$ of $\underline{z}^{(k)}$, we assign the 0th through $\left(k^{2}-1\right)$ th entries of the above code of $h\left(x_{g}\right)$ to $\widehat{\widehat{v}}^{(k)}$ as

$$
\underline{\widehat{v}}^{(k)}=\left(v_{0} v_{1} v_{2} \ldots v_{k^{2}-1}\right)
$$

This implies that $g$ has a non-trivial physical measure supported on the forward orbit of $x_{g}$. The remaining calculations are similar to those in the proof of KNS23, Theorem 5.5]. This concludes the proof of (1).

Next, let us prove (2). To realize historic behavior in the forward orbit starting from the contracting wandering domain $D=\operatorname{Int}\left(R_{1}\right)$, we prepare a code that oscillates between different dynamics in each generation and does not converge on any of them. The easiest way might be the following.

- (Era condition) We first consider an increasing sequence of integers $\left(k_{s}\right)_{s \in \mathbb{N}}$ such that, for every $s \in \mathbb{N}$,

$$
\begin{equation*}
\sum_{k=k_{s}}^{k_{s+1}-1} k^{2}>s \sum_{k=1}^{k_{s}-1} k^{2} \tag{9.5}
\end{equation*}
$$

Note that 9.5 provides the situation that the new era from 1 to $k_{s+1}-1$ is so dominant that the old era from 1 to $k_{s}-1$ is neglectable.

- (Code condition for oscillation) Under the condition 9.5), for each integer $k \geq 1$, let $\underline{v}^{(k)}=\left(v_{0} v_{1} v_{2} \ldots v_{k^{2}-1}\right)$ be the code whose entries satisfy the following rules:
(1) if $s$ is even and $k_{s} \leq k<k_{s+1}$,

$$
v_{i}= \begin{cases}0 & \text { for } i=0, \ldots,\left\lfloor k^{2} / 3\right\rfloor-1 \\ 1 & \text { for } i=\left\lfloor k^{2} / 3\right\rfloor, \ldots, k^{2}-1\end{cases}
$$

that is,

$$
\underline{\underline{v}}^{(k)}=\underbrace{0 \ldots 0}_{\left\lfloor k^{2} / 3\right\rfloor} \underbrace{111 \ldots \ldots 1}_{\left\lceil 2 k^{2} / 3\right\rceil},
$$

(2) if $s$ is odd and $k_{s} \leq k<k_{s+1}$,

$$
v_{i}= \begin{cases}0 & \text { for } i=0, \ldots,\left\lfloor 2 k^{2} / 3\right\rfloor-1 \\ 1 & \text { for } i=\left\lfloor 2 k^{2} / 3\right\rfloor, \ldots, k^{2}-1\end{cases}
$$

that is,

$$
\underline{\widehat{v}}^{(k)}=\underbrace{000 \ldots \ldots 0}_{\left\lfloor 2 k^{2} / 3\right\rfloor} \underbrace{1 \ldots 1}_{\left\lceil k^{2} / 3\right\rceil},
$$

where $\lfloor\cdot\rfloor$ and $\lceil\cdot\rceil$ indicate the floor and ceiling functions, respectively.
The above ratio values such as $1 / 3$ or $2 / 3$ are not so essential, but the ratios should vary depending on whether the era is even or odd.

Using the above results, one can obtain a wandering domain $D$ with historic behavior. In fact, consider the rectangle $R_{k}$ which is contained in $\mathbb{G} a_{k}^{\mathrm{u}}\left(n_{k} ; \underline{z}^{(k)}\right)$, where $\underline{z}^{(k)}=\widehat{\widehat{z}}^{(k)} \widehat{\widehat{v}}^{(k)}\left[\underline{\widehat{w}}^{(k+1)}\right]^{-1}$ and the middle part $\underline{\widehat{v}}^{(k)}$ satisfies the above code condition for oscillation. This implies that $D:=\operatorname{Int}\left(R_{1}\right)$ is a wandering domain of $g$ whose forward orbit has historic behavior. The remaining calculations are the same as the proof of [KNS23, Theorem 5.1]. This completes the proof of (2).
