# Interface motion from Glauber-Kawasaki dynamics of non-gradient type 

Tadahisa Funaki

April 30, 2024

#### Abstract

We consider the Glauber-Kawasaki dynamics on a $d$-dimensional periodic lattice of size $N$, that is, a stochastic time evolution of particles performing random walks with interaction subject to the exclusion rule (Kawasaki part), in general, of non-gradient type, together with the effect of the creation and annihilation of particles (Glauber part) whose rates are set to favor two levels of particle density, called sparse and dense. We then study the limit of our dynamics under the hydrodynamic space-time scaling, that is, $1 / N$ in space and a diffusive scaling $N^{2}$ for the Kawasaki part and another scaling $K=K(N)$, which diverges slower, for the Glauber part in time. In the limit as $N \rightarrow \infty$, we show that the particles autonomously make phase separation into sparse or dense phases at the microscopic level, and an interface separating two regions is formed at the macroscopic level and evolves under an anisotropic curvature flow.

In the present article, we show that the particle density at the macroscopic level is well approximated by a solution of a reaction-diffusion equation with a nonlinear diffusion term of divergence form and a large reaction term. Furthermore, by applying the results of Funaki, Gu and Wang arXiv:2404.12234 for the convergence rate of the diffusion matrix approximated by local functions, we obtain a quantitative hydrodynamic limit as well as the upper bound for the allowed diverging speed of $K=K(N)$.

The above result for the derivation of the interface motion is proved by combining our result with that in a companion paper by Funaki and Park arXiv:2403.01732, in which we analyzed the asymptotic behavior of the solution of the reaction-diffusion equation obtained in the present article and derived an anisotropic curvature flow in the situation where the macroscopic reaction term determined from the Glauber part is bistable and balanced. \|

## 1 Introduction - model and results

The present article studies the hydrodynamic behavior of the Glauber-Kawasaki dynamics with a diverging scaling parameter $K$ in the Glauber part. The Kawasaki part governs the

[^0]time evolution of particles moving as interacting random walks subject to the exclusion rule. It is generally of non-gradient type and we assume its reversibility under Bernoulli measures. The Glauber part prescribes the law of creation and annihilation of particles. Here we quote the original papers [16] by Glauber and [18] by Kawasaki initially designed for stochastic dynamics corresponding to the Ising model. We show that, in particular in the situation that the particles have two favorable stable phases called 'sparse' and 'dense' with different mean densities, they autonomously undergo phase separation into one of these two phases at the microscopic level, and an interface separating the two regions is formed at the macroscopic level and it evolves under an anisotropic curvature flow; see Theorem 1.4 .

To show this, in the present article, we establish that the particle density at the macroscopic level is well approximated by the solution of a reaction-diffusion equation with nonlinear diffusion and a diverging reaction term; see Theorem 1.1, The asymptotic behavior of the solution of this equation is studied in a separate article [12] based on a method in partial differential equations (PDEs); see Theorems 1.2 and 1.3 , Combining these results, we can complete the derivation of the interface motion from our particle systems. Note that the PDE is used only secondarily.

The present article extends the results obtained in [10], 3] for the Glauber-Kawasaki dynamics or the Glauber-Zero range process of gradient type to a model of non-gradient type. Moreover, applying the results in [9, we obtain a quantitative hydrodynamic limit with its convergence rate and also the upper bound for the allowed diverging speed of $K=K(N)$ in the Glauber part.

### 1.1 Model at microscopic level

Let us formulate our model. We consider the Glauber-Kawasaki dynamics on a $d$-dimensional periodic square lattice $\mathbb{T}_{N}^{d}=(\mathbb{Z} / N \mathbb{Z})^{d} \equiv\{1,2, \ldots, N\}^{d}$ of large size $N \in \mathbb{N} \equiv\{1,2, \ldots\}$. The generator $\mathcal{L}_{N}$ of our dynamics is given by the sum of those of Kawasaki and Glauber dynamics with time change factors $N^{2}$ and $K=K(N) \geq 1$, respectively:

$$
\begin{equation*}
\mathcal{L}_{N}=N^{2} L_{K}+K L_{G} \tag{1.1}
\end{equation*}
$$

The Kawasaki part is the same as in [14, 6]. It is of non-gradient type and reversible under Bernoulli measures; see (1.2) and the conditions (1)-(3) below. The hydrodynamic scaling limit for the Kawasaki dynamics reversible under Gibbs measures was studied by [29]. In [10], [11], the so-called gradient condition was assumed for the Kawasaki part but here we discuss without assuming it.

To define the operators $L_{K}$ and $L_{G}$ precisely, we introduce several notations. The configuration space of the dynamics is $\mathcal{X}_{N}=\{0,1\}^{\mathbb{T}_{N}^{d}}$ whose element is denoted by $\eta=$ $\left\{\eta_{x} ; x \in \mathbb{T}_{N}^{d}\right\}$ where $\eta_{x}=0$ or 1 indicates that the site $x$ is vacant or occupied, respectively. We denote $\mathcal{F}_{N}$ the set of all functions on $\mathcal{X}_{N}$. Let $\tau_{x}, x \in \mathbb{T}_{N}^{d}$, be the shift operators acting on $\mathcal{X}_{N}$ by $\left(\tau_{x} \eta\right)_{y}=\eta_{y+x}, y \in \mathbb{T}_{N}^{d}$, where addition is modulo $N$. They also act on $\mathcal{F}_{N}$ by $\left(\tau_{x} f\right)(\eta)=f\left(\tau_{x} \eta\right), f \in \mathcal{F}_{N}$.

For $x, y \in \mathbb{T}_{N}^{d}$ and $\eta \in \mathcal{X}_{N}, \eta^{x, y}$ denotes the element of $\mathcal{X}_{N}$, obtained from $\eta$ by
exchanging the values of $\eta_{x}$ and $\eta_{y}$, that is,

$$
\left(\eta^{x, y}\right)_{z}= \begin{cases}\eta_{y}, & \text { if } z=x \\ \eta_{x}, & \text { if } z=y \\ \eta_{z}, & \text { if } z \neq x, y\end{cases}
$$

For $x \in \mathbb{T}_{N}^{d}$ and $\eta \in \mathcal{X}_{N}, \eta^{x}$ denotes the element of $\mathcal{X}_{N}$, obtained from $\eta$ by flipping the value of $\eta_{x}$, that is,

$$
\left(\eta^{x}\right)_{z}=\left\{\begin{array}{cl}
1-\eta_{x}, & \text { if } z=x \\
\eta_{z}, & \text { if } z \neq x
\end{array}\right.
$$

The notations $\tau_{x}, \eta^{x, y}$ and $\eta^{x}, x, y \in \mathbb{Z}^{d}$ also indicate the corresponding ones for $\mathcal{X}=\{0,1\}^{\mathbb{Z}^{d}}$, the configuration space on the whole lattice $\mathbb{Z}^{d}$. For $\Lambda \subset \mathbb{T}_{N}^{d}$ or $\subset \mathbb{Z}^{d}$, $(\Lambda)^{*}$ denotes the set of all (undirected) bonds $b=\{x, y\}$ inside $\Lambda$, i.e., $x, y \in \Lambda$ and $|x-y|=1$. Throughout the paper, we use the norm $|z|$ for $z=\left(z_{i}\right)_{i=1}^{d} \in \mathbb{Z}^{d}$ in $\ell^{1}$-sense: $|z|=\max _{1 \leq i \leq d}\left|z_{i}\right|$. We sometimes write $\eta^{b}$ instead of $\eta^{x, y}$ for bonds $b=\{x, y\}$.

The generator $L_{K}$ of the Kawasaki part on $\mathbb{T}_{N}^{d}$ is defined as

$$
\begin{equation*}
L_{K}=\sum_{b \in\left(\mathbb{T}_{N}^{d}\right)^{*}} c_{b}(\eta) \pi_{b}=\frac{1}{2} \sum_{x, y \in \mathbb{T}_{N}^{d}:|x-y|=1} c_{x, y}(\eta) \pi_{x, y} \tag{1.2}
\end{equation*}
$$

where $\pi_{b} \equiv \pi_{x, y}, b=\{x, y\}$, is the exchange operator on $\mathcal{F}_{N}$ defined by

$$
\pi_{b} f(\eta)=f\left(\eta^{b}\right)-f(\eta), \quad f \in \mathcal{F}_{N}
$$

The functions $\left\{c_{b}(\eta) \equiv c_{x, y}(\eta) ; b=\{x, y\} \in\left(\mathbb{Z}^{d}\right)^{*}\right\}$ are defined on $\mathcal{X}$ and determine the jump (or exchange) rates of particles between two neighboring sites $x$ and $y$. We assume that they satisfy the following three conditions (1)-(3):
(1) Non-degeneracy and locality: $c_{x, y}(\eta)>0$ and it is local, that is, it depends only on $\left\{\eta_{z} ;|z-x| \leq r\right\}$ for some $r>0$.
(2) Spatial homogeneity: $c_{x, y}=\tau_{x} c_{0, y-x}$ for every $\{x, y\} \in\left(\mathbb{Z}^{d}\right)^{*}$.
(3) Detailed balance under Bernoulli measures: $c_{x, y}(\eta)$ does not depend on $\left\{\eta_{x}, \eta_{y}\right\}$.

In view of $(1)$, the jump rate $c_{b}(\eta)$ is naturally regarded as a function on $\mathcal{X}_{N}$ for $b \in\left(\mathbb{T}_{N}^{d}\right)^{*}$, at least if $N$ is large enough such that $N>2 r$. The third condition (3) is equivalent to the symmetricity of $L_{K}$ with respect to the Bernoulli measures $\nu_{\rho}^{N}, \rho \in[0,1]$, that is, the product probability measures on $\mathcal{X}_{N}$ such that $\nu_{\rho}^{N}\left(\eta_{x}=1\right)=\rho$ for every $x \in \mathbb{T}_{N}^{d}$. We will denote the Bernoulli measures on $\mathcal{X}$ by $\nu_{\rho}$, under which the operator $L_{K}$ considered on $\mathbb{Z}^{d}$ is symmetric; see [8], [10]. Note that we do not assume the gradient condition; cf. [8], [10].

On the other hand, the generator $L_{G}$ of the Glauber part is given by

$$
L_{G}=\sum_{x \in \mathbb{T}_{N}^{d}} c_{x}(\eta) \pi_{x}
$$

where $\pi_{x}, x \in \mathbb{T}_{N}^{d}$, is the flip operator on $\mathcal{F}_{N}$ defined by

$$
\pi_{x} f(\eta)=f\left(\eta^{x}\right)-f(\eta), \quad f \in \mathcal{F}_{N}
$$

For the flip rates $c_{x}(\eta)$ defined on $\mathcal{X}$, we assume the non-negativity, the locality and the spatial homogeneity, that is, $c_{x}(\eta)=\tau_{x} c(\eta)$ for some local function $c(\eta)=c_{0}(\eta) \geq 0$ on $\mathcal{X}$ (regarded as that on $\mathcal{X}_{N}$ for $N$ large enough). Since $\eta_{0}$ takes values only in $\{0,1\}, c(\eta)$ can be decomposed as

$$
\begin{equation*}
c(\eta)=c^{+}(\eta)\left(1-\eta_{0}\right)+c^{-}(\eta) \eta_{0} \tag{1.3}
\end{equation*}
$$

for some local functions $c^{ \pm}(\eta)$ which do not depend on $\eta_{0}$. We interpret $c^{+}(\eta)$ and $c^{-}(\eta)$ as the rates of creation and annihilation of a particle at $x=0$, respectively.

Let $\eta^{N}(t)=\left\{\eta_{x}^{N}(t) ; x \in \mathbb{T}_{N}^{d}\right\}$ be the Markov process on $\mathcal{X}_{N}$ governed by the infinitesimal generator $\mathcal{L}_{N}$ in (1.1) with properly taken $K$ such that $1 \leq K=K(N) \nearrow \infty$ as $N \rightarrow \infty$. We are interested in the asymptotic behavior as $N \rightarrow \infty$ of its macroscopic empirical mass distribution, that is, the measure-valued process defined by

$$
\begin{equation*}
\rho^{N}(t, d v)=N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \eta_{x}^{N}(t) \delta_{x / N}(d v), \quad v \in \mathbb{T}^{d} \tag{1.4}
\end{equation*}
$$

where $\mathbb{T}^{d}=\mathbb{R}^{d} / \mathbb{Z}^{d}$ is a $d$-dimensional continuous torus identified with $[0,1)^{d}$ and $\delta_{v}$ is the $\delta$-measure at $v$.

Our main result can be stated as follows. We consider the situation, under a proper choice of rates $\left\{c_{x, y}, c_{x}\right\}$, that the particles favor two levels of mean densities $\rho_{+}$and $\rho_{-} \in(0,1)$ with the same degree of stability. We then prove that $\rho^{N}(t, d v)$ converges to $\rho_{+} d v$ or $\rho_{-} d v$ on two regions separated by a hypersurface $\Gamma_{t}$ called the interface and $\Gamma_{t}$ evolves under the anisotropic curvature flow; see Theorem [1.4. We also give the rate of convergence in probability.

The proof is divided into two parts, that is, a probabilistic part which is developed in this article and a PDE part summarized in Theorems 1.2 and 1.3 , shown in 12 .

### 1.2 Diffusion matrix and reaction term at macroscopic level

To state our result for the hydrodynamic limit, which is the main contribution of this article, first corresponding to the Kawasaki part, we introduce a quadratic form $(\theta, \widehat{c}(\rho) \theta), \theta \in$ $\mathbb{R}^{d}$, for each $\rho \in[0,1]$ called the conductivity via the variational formula

$$
\begin{equation*}
(\theta, \widehat{c}(\rho) \theta)=\inf _{F \in \mathcal{F}_{0}^{d}}(\theta, \widehat{c}(\rho ; F) \theta) \tag{1.5}
\end{equation*}
$$

where $(\cdot, \cdot)$ is the inner product of $\mathbb{R}^{d}, \mathcal{F}_{0}$ denotes the class of all local functions on $\mathcal{X}$, $\mathcal{F}_{0}^{d}=\left(\mathcal{F}_{0}\right)^{d}$,

$$
(\theta, \widehat{c}(\rho ; F) \theta)=\frac{1}{2} \sum_{|x|=1}\left\langle c_{0, x}\left(\theta, x\left(\eta_{x}-\eta_{0}\right)-\pi_{0, x}\left(\sum_{y \in \mathbb{Z}^{d}} \tau_{y} F\right)\right)^{2}\right\rangle_{\rho}
$$

and $\langle\cdot\rangle_{\rho} \equiv E^{\nu_{\rho}}[\cdot]$ stands for the expectation with respect to the Bernoulli measure $\nu_{\rho}$ on $\mathcal{X}$. Note that $\pi_{0, x}\left(\sum_{y \in \mathbb{Z}^{d}} \tau_{y} F\right)$ is well-defined as a finite sum $\sum_{y \in \mathbb{Z}^{d}} \pi_{0, x}\left(\tau_{y} F\right)$. We choose a $d \times d$ symmetric matrix $\widehat{c}(\rho)=\left\{\widehat{c}_{i j}(\rho)\right\}_{1 \leq i, j \leq d}$, which is written in the same notation, corresponding to the quadratic form introduced above, especially to apply results in partial differential equations; cf. Remark after Theorem 1.1 of [14.

We also introduce the compressibility:

$$
\begin{equation*}
\chi(\rho)=\rho-\rho^{2}, \tag{1.6}
\end{equation*}
$$

and the diffusion matrix $D(\rho)=\left\{D_{i j}(\rho)\right\}_{1 \leq i, j \leq d}$ by the Einstein relation:

$$
\begin{equation*}
D(\rho)=\frac{\widehat{c}(\rho)}{2 \chi(\rho)}, \quad \rho \in[0,1], \tag{1.7}
\end{equation*}
$$

see Proposition 2.2 of [25], p. 180 for the relation to the Green-Kubo formula. It is known that $D(\rho)$ is a $C^{\infty}$-function of $\rho \in[0,1]$ :

$$
\begin{equation*}
D \in C^{\infty}([0,1]), \tag{1.8}
\end{equation*}
$$

see [1]. Furthermore, the diffusion matrix $D(\rho)$ is uniformly positive and bounded:

$$
\begin{equation*}
c_{*}|\theta|^{2} \leq(\theta, D(\rho) \theta) \leq c^{*}|\theta|^{2}, \quad \theta \in \mathbb{R}^{d}, \rho \in[0,1], \tag{1.9}
\end{equation*}
$$

where $c_{*}, c^{*}>0$ are constants defined by

$$
0<c_{*}:=\min _{\eta \in \mathcal{X}, x \in \mathbb{Z}^{d}:|x|=1} c_{0, x}(\eta) \leq c^{*}:=\max _{\eta \in \mathcal{X}, x \in \mathbb{Z}^{d}:|x|=1} c_{0, x}(\eta)<\infty,
$$

which follows from the condition (1); see [26] and Lemma 8.1] below for the proof of (1.9).
Next, corresponding to the Glauber part, we introduce a function $f=f(\rho)$ as an ensemble average under $\nu_{\rho}$ as follows:

$$
\begin{align*}
f(\rho) & =\left\langle\left(1-2 \eta_{0}\right) c(\eta)\right\rangle_{\rho}  \tag{1.10}\\
& =(1-\rho)\left\langle c^{+}\right\rangle_{\rho}-\rho\left\langle c^{-}\right\rangle_{\rho} .
\end{align*}
$$

Note that $f$ is a polynomial of $\rho$ and, in particular, a $C^{\infty}$-function of $\rho \in[0,1]$. Note also that $f(0)>0$ and $f(1)<0$, which is important to show the comparison theorem; see Section 7.

### 1.3 Quantitative and non-gradient hydrodynamic limit

We show that, asymptotically as $N \rightarrow \infty$, the macroscopic empirical mass distribution $\rho^{N}(t, d v)$ is close to the solution $\rho(t, v)=\rho_{K}(t, v)$ of the following reaction-diffusion equation with a nonlinear diffusion term and a diverging factor $K=K(N)$ in a reaction term

$$
\begin{equation*}
\partial_{t} \rho(t, v)=\sum_{i, j=1}^{d} \partial_{v_{i}}\left\{D_{i j}(\rho(t, v)) \partial_{v_{j}} \rho(t, v)\right\}+K f(\rho(t, v)), \quad t \geq 0, v \in \mathbb{T}^{d}, \tag{1.11}
\end{equation*}
$$

where $v=\left(v_{i}\right)_{i=1}^{d}$. We assume that its initial value $\rho_{0}(v)$ satisfies the condition:

$$
\begin{equation*}
\rho_{0} \in C^{5}\left(\mathbb{T}^{d}\right) \quad \text { and } \quad 0<\rho_{0}(v)<1 . \tag{1.12}
\end{equation*}
$$

Then, the equation (1.11) has a unique classical solution $\rho(t, v) \in C^{1,3}\left([0, \infty) \times \mathbb{T}^{d}\right)$ by applying the results in [20; see the beginning of Section 6,

To state our result, let $\nu^{N} \equiv \nu_{1 / 2}^{N}$ be the Bernoulli measure on $\mathcal{X}_{N}$ with $\rho=1 / 2$, that is, the uniform probability measure on $\mathcal{X}_{N}: \nu^{N}(\eta)=2^{-N}, \eta \in \mathcal{X}_{N}$. For two probability densities $f$ and $g$ with respect to $\nu^{N}$, define the relative entropy $H(f \mid g) \equiv H_{N}(f \mid g)$ by

$$
\begin{equation*}
H(f \mid g)=\int_{\mathcal{X}_{N}} f \log (f / g) d \nu^{N} \tag{1.13}
\end{equation*}
$$

We set

$$
\begin{equation*}
\bar{\rho}(\lambda)=e^{\lambda} /\left(e^{\lambda}+1\right), \quad \lambda \in \mathbb{R}, \tag{1.14}
\end{equation*}
$$

and denote its inverse function by $\bar{\lambda}(\rho)$ :

$$
\begin{equation*}
\bar{\lambda}(\rho)=\log \{\rho /(1-\rho)\}, \quad \rho \in(0,1) . \tag{1.15}
\end{equation*}
$$

Let $f_{0}=f_{0}(\eta), \eta \in \mathcal{X}_{N}$, be the (initial) density of the distribution of $\eta^{N}(0)$ on $\mathcal{X}_{N}$ with respect to $\nu^{N}$ and, for $\rho_{0}=\rho_{0}(v)$ satisfying (1.12), let

$$
\begin{equation*}
\widetilde{\psi}_{0}(\eta)=Z_{N}^{-1} \exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \bar{\lambda}\left(\rho_{0}(x / N)\right) \eta_{x}\right\} \tag{1.16}
\end{equation*}
$$

with $\bar{\lambda}$ defined by (1.15) and a normalization constant $Z_{N}$ with respect to $\nu^{N}$. In other words, $\widetilde{\psi}_{0} d \nu^{N}$ denoted also by $P^{\widetilde{\psi}_{0}}$ is a product measure on $\mathcal{X}_{N}$ with a marginal distribution $P^{\widetilde{\psi}_{0}}\left(\eta_{x}=1\right)=\rho_{0}(x / N)$ for every $x \in \mathbb{T}_{N}^{d}$.

Then, the difference between $\rho^{N}(t, d v)$ and $\rho_{K}(t, v) d v$ with $K=K(N)$ is estimated in probability as in the following theorem. We call it a quantitative hydrodynamic limit, since it gives the convergence rate. Note that $\rho_{K}$ is moving in $N$. To set the upper threshold for the allowed $K=K(N)$, define

$$
\begin{equation*}
\bar{K}(N) \equiv \bar{K}_{\delta}(N):=\delta \log N, \tag{1.17}
\end{equation*}
$$

for $\delta>0$.
Theorem 1.1. For each $K \geq 1$, let $\rho_{K}(t, v)$ be the solution of the equation (1.11) with an initial value $\rho_{0}(v)$ that satisfies the condition (1.12). We assume that $f_{0}$ and $\widetilde{\psi}_{0}$ defined above satisfy $H\left(f_{0} \mid \widetilde{\psi}_{0}\right) \leq C_{1} N^{d-\kappa_{1}}$ for some $C_{1}>0$ and $\kappa_{1}>0$. Then, there exist $\kappa>0$ and $\mathfrak{c}>0$ small enough such that for any $T>0$, taking $\delta=\delta_{T}:=\mathfrak{c} / T$ in $\bar{K}_{\delta}(N)$, if $K=K(N)$ satisfies $1 \leq K(N) \leq \bar{K}_{\delta}(N)$ and $K(N) \rightarrow \infty$, we have

$$
P\left(\left|\left\langle\rho^{N}(t), \phi\right\rangle-\left\langle\rho_{K}(t), \phi\right\rangle\right|>\varepsilon\right) \leq C N^{-\kappa}
$$

for all $t \in[0, T], \varepsilon>0$ and $\phi \in C^{\infty}\left(\mathbb{T}^{d}\right)$ for some $C=C_{T}(\varepsilon, \phi)>0$, where $\langle\rho, \phi\rangle=$ $\int_{\mathbb{T}^{d}} \phi(v) \rho(d v)$ for a measure $\rho=\rho(d v)$ on $\mathbb{T}^{d}$ and $\rho_{K}(t)$ is identified with $\rho_{K}(t, v) d v$.

The constants $\kappa>0, \mathfrak{c}>0$ and $\delta>0$ in $\bar{K}_{\delta}(N)$ are chosen in Section 5.2. In fact, to make $\kappa>0$, the product $\delta \cdot T$ must be small enough and this determines $\mathfrak{c}>0$. Once $\mathfrak{c}$ is determined, we choose $\delta=\delta_{T}=\mathfrak{c} / T$. In this sense, $\kappa$ depends on $\mathfrak{c}$, but it is independent of $\delta$ and $T$. Especially if $f_{0}=\widetilde{\psi}_{0}$, the assumption for $H\left(f_{0} \mid \widetilde{\psi}_{0}\right)$ in this theorem is fulfilled. In [3], [10, a similar theorem was shown for models of gradient type; see also [11]. In particular, it was shown that the theorem holds taking $\bar{K}(N)=\delta(\log N)^{\sigma / 2}$ for some small $\delta>0$ and some $\sigma \in(0,1)$. The bound for $\bar{K}(N)$ in Theorem 1.1 is better than this. The reason is that our estimates are more accurate for several error terms. Moreover, for our non-gradient model, new results obtained in 9 based on the method of the quantitative homogenization theory are essential to derive the above decay rate $C N^{-\kappa}$ and also to determine the upper bound $\bar{K}(N)$.

Theorem 1.1] reduces the study of the limit of $\rho^{N}(t, d v)$ as $N \rightarrow \infty$ to that of $\rho_{K}(t, v)$ as $K \rightarrow \infty$. The latter is a pure PDE problem and is discussed separately in a companion paper [12]. The results are summarized in the next subsection.

### 1.4 Interface motion from nonlinear Allen-Cahn equation

We now consider the case that $d \geq 2$ and assume that the reaction term $f(\rho)$ in (1.11) is bistable, i.e. $f$ has three zeros $0<\rho_{-}<\rho_{*}<\rho_{+}<1$ such that $f^{\prime}\left(\rho_{ \pm}\right)<0$ and $f^{\prime}\left(\rho_{*}\right)>0$. In addition, we assume the balance condition:

$$
\int_{\rho_{-}}^{\rho_{+}} f(\rho) D(\rho) d \rho=0 .
$$

This means that two stable phases with densities $\rho_{ \pm}$, sparse and dense, have the same degree of stability. Recalling the condition (1.12) for the initial value $\rho_{0}(v)$, we define $\Gamma_{0}$ by

$$
\Gamma_{0}:=\left\{v \in \mathbb{T}^{d}: \rho_{0}(v)=\rho_{*}\right\}
$$

and assume that $\Gamma_{0}$ is a $C^{5}$-hypersurface in $\mathbb{T}^{d}$ without boundary such that

$$
\begin{equation*}
\nabla \rho_{0}(v) \cdot n(v) \neq 0 \text { for } v \in \Gamma_{0} \tag{1.18}
\end{equation*}
$$

where $n(v)$ is the normal vector to $\Gamma_{0}$. Two regions $\Omega_{0}^{ \pm}$surrounded by $\Gamma_{0}$ are defined by $\Omega_{0}^{+}=\left\{\rho_{0}>\rho_{*}\right\}$ and $\Omega_{0}^{-}=\left\{\rho_{0}<\rho_{*}\right\}$, respectively.

Then, one can show that

$$
\rho_{K}(t, v) \rightarrow \Xi_{\Gamma_{t}}(v) \quad \text { as } K \rightarrow \infty .
$$

Here, $\Gamma_{t}$ is a smooth closed hypersurface in $\mathbb{T}^{d}$ and $\Xi_{\Gamma_{t}}$ is a step function taking two values $\rho_{ \pm}$defined by

$$
\Xi_{\Gamma_{t}}(v)= \begin{cases}\rho_{+}, & v \in \Omega_{t}^{+}, \\ \rho_{-}, & v \in \Omega_{t}^{-},\end{cases}
$$

where $\Omega_{t}^{ \pm}$are two regions surrounded by $\Gamma_{t}$. The sides of these regions are determined initially at $t=0$ and then continuously for $t>0$.

The evolution of $\Gamma_{t}$ starting from $\Gamma_{0}$ is governed by the equation

$$
\begin{equation*}
V=-\operatorname{Tr}\left(\mu(n) \partial_{v} n\right) \equiv-\sum_{i, j=1}^{d} \mu_{i j}(n) \partial_{v_{i}} n_{j} \quad \text { on } \quad \Gamma_{t}, \tag{1.19}
\end{equation*}
$$

where $V$ is the normal velocity of $\Gamma_{t}$ from the side of $\Omega_{t}^{-}$to $\Omega_{t}^{+}$and $n=\left(n_{i}\right)$ denotes the unit normal vector to $\Gamma_{t}$ of the same direction. This describes an anisotropic (direction dependent) curvature flow. It is a mean curvature flow in the special case that $\mu_{i j}(e)=\mu \delta_{i j}$ with a constant $\mu$.

The matrix $\mu(e)=\left\{\mu_{i j}(e)\right\}_{1 \leq i, j \leq d}$ is defined for $e \in \mathbb{R}^{d}:|e|=1$ as

$$
\begin{aligned}
\mu_{i j}(e) & =\frac{1}{\lambda(e)} \int_{\rho_{-}}^{\rho_{+}}\left[D_{i j}(\rho) \sqrt{W_{e}(\rho)}-\frac{1}{2} \partial_{e_{i}}\left(W_{e}(\rho)\right) \partial_{e_{j}}\left(\frac{a_{e}(\rho)}{\sqrt{W_{e}(\rho)}}\right)\right] d \rho, \\
\lambda(e) & =\int_{\rho_{-}}^{\rho_{+}} \sqrt{W_{e}(\rho)} d \rho, \quad W_{e}(\rho)=-2 \int_{\rho_{-}}^{\rho} a_{e}(\rho) f(\rho) d \rho, \quad a_{e}(\rho)=e \cdot D(\rho) e .
\end{aligned}
$$

Note that $W_{e}(\rho) \geq 0$ for $\rho \in\left[\rho_{-}, \rho_{+}\right]$by the conditions for $f(\rho)$.
The local-in-time well-posedness on a certain time interval $[0, T]$ with $T>0$ of the equation (1.19) follows from the non-degeneracy of $\mu(e)$ in the tangential direction to the interface $\Gamma$ : For some $c>0$,

$$
(\theta, \mu(e) \theta) \geq c|\theta|^{2} \quad \text { for } \theta \in \mathbb{R}^{d} \text { such that }(\theta, e)=0
$$

Note that (1.19) can be rewritten in an equivalent PDE for the signed distance function $d(t, v)$ from $\Gamma_{t}$; see [12].

The first result is for the generation of the interface, that is, $\rho_{K}(t, v)$ reaches the neighborhood of $\rho_{-}$or $\rho_{+}$in a very short time of order $K^{-1} \log K$.

Theorem 1.2. (Theorem 1.1 of [12] on $\Omega=\mathbb{T}^{d}$ ) Let $\rho_{K}(t, v)$ be the solution of the equation (1.11) and let $\epsilon$ be such that $0<\epsilon<\bar{\rho}$, where $\bar{\rho}:=\min \left\{\rho_{+}-\rho_{*}, \rho_{*}-\rho_{-}\right\}$. We assume the conditions given at the beginning of this subsection. Then, there exist $K_{0}>0$ and $M_{0}>0$ such that, for all $K \geq K_{0}$, the following holds at $t=t_{K}:=K^{-1} \log K /\left(2 f^{\prime}\left(\rho_{*}\right)\right)$.
(1) $\rho_{-}-\epsilon \leq \rho_{K}\left(t_{K}, v\right) \leq \rho_{+}+\epsilon$ for all $v \in \mathbb{T}^{d}$,
(2) $\rho_{K}\left(t_{K}, v\right) \geq \rho_{+}-\epsilon$ for $v \in \mathbb{T}^{d}$ such that $\rho_{0}(v) \geq \rho_{*}+M_{0} / K^{1 / 2}$,
(3) $\rho_{K}\left(t_{K}, v\right) \leq \rho_{-}+\epsilon$ for $v \in \mathbb{T}^{d}$ such that $\rho_{0}(v) \leq \rho_{*}-M_{0} / K^{1 / 2}$.

The second result is for the propagation of the interface, that is, the derivation of the interface motion $\Gamma_{t}$ as long as it remains smooth. The size of the transition layer is $O\left(K^{-1 / 2}\right)$.
Theorem 1.3. (Theorem 1.2 of [12]) Under the conditions of Theorem [1.2, for any $0<$ $\epsilon<\bar{\rho}$, there exist $K_{0}>0, C>0$ and $T>0$ (within the local-in-time well-posedness of (1.19)) such that for every $K \geq K_{0}$ and $t \in\left[t_{K}, T\right]$ we have

$$
\rho_{K}(t, v) \in \begin{cases}{\left[\rho_{-}-\epsilon, \rho_{+}+\epsilon\right]} & \text { for all } v \in \mathbb{T}^{d}, \\ {\left[\rho_{+}-\epsilon, \rho_{+}+\epsilon\right]} & \text { if } v \in \Omega_{t}^{+} \backslash \mathcal{N}_{C / K^{1 / 2}}\left(\Gamma_{t}\right), \\ {\left[\rho_{-}-\epsilon, \rho_{-}+\epsilon\right]} & \text { if } v \in \Omega_{t}^{-} \backslash \mathcal{N}_{C / K^{1 / 2}}\left(\Gamma_{t}\right),\end{cases}
$$

where $\mathcal{N}_{r}\left(\Gamma_{t}\right):=\left\{v \in \mathbb{T}^{d}, \operatorname{dist}\left(v, \Gamma_{t}\right) \leq r\right\}$ is the $r$-neighborhood of $\Gamma_{t}$.
The proofs of these two theorems are given based on the comparison theorem for the PDE (1.11). We construct its super and sub solutions. If the PDE (1.11) is a gradient flow of a certain functional, one can apply the method of $\Gamma$-convergence to derive the motion of $\Gamma_{t}$. In particular, if the energy in the limit is a total surface tension, one would obtain an evolution of Wulff shape. But our equation is different from this class.

### 1.5 Main result

The following theorem is obtained for the particle system $\eta^{N}(t)$ by combining Theorems 1.1 and 1.3

Theorem 1.4. Assume the condition (1.12) for the initial value $\rho_{0}(v)$ and $H\left(f_{0} \mid \widetilde{\psi}_{0}\right) \leq$ $C_{1} N^{d-\kappa_{1}}$ for some $C_{1}>0$ and $\kappa_{1}>0$ in Theorem 1.1 and those in Theorem 1.3, that is, $d \geq 2, f(\rho)$ determined in (1.10) from the flip rate of the Glauber part and the initial value $\rho_{0}(v)$ satisfy the conditions given at the beginning of Section 1.4. Then, we have

$$
P\left(\left|\left\langle\rho^{N}(t), \phi\right\rangle-\left\langle\Xi_{\Gamma_{t}}, \phi\right\rangle\right|>\varepsilon\right) \leq C N^{-\kappa}
$$

for all $t \in(0, T], \varepsilon>0$ and $\phi \in C^{\infty}\left(\mathbb{T}^{d}\right)$ for some $C=C_{T}(\varepsilon, \phi)$, where $T>0$ is determined as in Theorem 1.3 and $\kappa>0$ as in Theorem [1.1.

Proof. Noting that $\Xi_{\Gamma_{t}}=\rho_{+} 1_{\Omega_{t}^{+}}+\rho_{-} 1_{\Omega_{t}^{-}}$and $\left|\mathbb{T}^{d}\right|=1$, for any $0<\epsilon<\bar{\rho}$, we have by Theorem 1.3

$$
\left|\left\langle\rho_{K}(t), \phi\right\rangle-\left\langle\Xi_{\Gamma_{t}}, \phi\right\rangle\right| \leq\left(\epsilon+\left(C_{\epsilon} / K^{1 / 2}\right)^{d-1} \cdot\left|\Gamma_{t}\right|\right)\|\phi\|_{\infty}
$$

for $K \geq K_{0}=K_{0, \epsilon}$ and $t \in\left[t_{K}, T\right]$. Choosing $\epsilon>0$ small enough and $K \geq K_{0}$ large enough, since $\left|\Gamma_{t}\right|$ is bounded, one can make the right-hand side smaller than $\varepsilon / 2$. Note also that $t_{K}$ is small for $K$ large. Thus, taking $K=\bar{K}_{\delta_{T}}(N) \vee K_{0}$ and $C=C_{T}(\varepsilon / 2, \phi)$, the concluding estimate follows from Theorem 1.1 at least for large $N$.

This theorem establishes the autonomous phase separation directly for the particle system. The PDE (1.11) was used only secondarily. We set the flip rate $c_{0}$ in the Glauber part as the corresponding $f$ determined in (1.10) to satisfy the bistability and balance conditions. This means that the particles prefer two phases with mean densities $\rho_{-}$or $\rho_{+}$.

From gradient models, we derived the mean curvature flow, i.e., $\mu_{i j}(e)=\mu \delta_{i j}$; see [3], [4], 10] and also [17]. In the unbalanced case for gradient models assuming that $D(\rho) \equiv D$ (constant), on a shorter time scale such as $O\left(1 / K^{1 / 2}\right)$, Huygens' principle was derived. In other words, the stronger phase region expands with a constant speed; see [11]. See [7] for other approaches.

### 1.6 Outline of the article

The article is organized as follows. In Section 2, following [14], we introduce a local equilibrium state $\psi_{t}(\eta)$ of second order approximation with a leading order term determined by the hydrodynamic equation (1.11). We then prove that Theorem 1.1 is shown once one
can prove the bound $N^{-d} H\left(f_{t} \mid \psi_{t}\right) \leq C N^{-\kappa}$ for some $C, \kappa>0$ for the relative entropy per volume of the density $f_{t}(\eta)$ of the distribution of the process $\eta^{N}(t)$ with respect to $\psi_{t}(\eta)$ with a properly chosen second order term $F(\eta)$. This bound is formulated in Proposition 2.1.

The proof of Proposition 2.1 is given in Section 3. Differently from [14, our model has the Glauber part and it includes a diverging factor $K=K(N)$. Moreover, in order to establish a quantitative hydrodynamic limit, we need a decay estimate for the relative entropy per volume. This forces us to derive sufficiently strong error estimates at all steps of the proof. We first calculate the time derivative of $H\left(f_{t} \mid \psi_{t}\right)$ for general $\psi_{t}$ along with obtaining careful error estimates; see Lemma 3.1. Second, we show the refined one-block estimate, that is, the replacement of microscopic functions (even those with a diverging factor $K$ ) by their ensemble averages with fine error estimates based on the argument in [10] and the equivalence of ensembles with precise convergence rate; see Theorem 3.3. Third, we show the Boltzmann-Gibbs principle for the gradient replacement, by which one can replace a microscopic function looking of order $O(N)$ but with vanishing ensemble average by a linear function of $\eta_{x}$ of gradient form with a properly chosen coefficient; see Theorem 3.5. This theorem, which gives good error estimates for the replacement, is shown by using the decay estimates for the CLT variances given in Section [4. We then need Lemma 3.7 to replace the linear function of $\eta_{x}$ of gradient form with a function of order $O(1)$.

The estimates obtained so far are summarized in Lemma 3.8. To give a further bound for an expectation under $f_{t}$ (which is an unknown distribution) by that under $\psi_{t}$ (which is a well-understood distribution), we apply the entropy inequality. Then, we are required to show the large deviation type upper bound under $\psi_{t}$ with fine error estimates; see Theorem 3.9 and Theorem 3.11 as its consequence.

One can observe that the leading term in the estimate in Theorem 3.11 is cancelled if we determine the leading term of $\psi_{t}$ according to the hydrodynamic equation (1.11); see Lemma 3.13. The equation (1.11) is used only for this lemma. Summarizing these and choosing $K=K(N)$ and other parameters properly as indicated in Section 5, one can conclude the proof of Proposition [2.1. We apply multiscale analysis with different scaling parameters $1 \ll n \ll \ell \ll N$. The proof of Theorem 3.9 is given in Section 3.8.

Section 4 concerns the CLT variances related to the gradient replacement and deals with quantities determined only by the localized Kawasaki generator and under the Bernoulli measures $\left\{\nu_{\rho}\right\}_{\rho}$. In particular, the Glauber part plays no role in this section. Proposition 4.1 is a refinement of Proposition 5.1 of [14. We provide a decay estimate for the error terms in the CLT variances, which was not given in [14]. We use the equivalence of ensembles with a precise convergence rate. Then, for the decay rate for the CLT variance of the term $A_{\ell}$, we have Theorem 4.2 as a refinement of Theorem 5.1 of [14]. This is the key to the gradient replacement and is obtained by applying new results of [9]. We note that Theorem 5.1 of [14] gave only the convergence without rate and was shown based on the so-called characterization of the closed forms originally due to Varadhan [28]; cf. [19]. This is however not sufficient for our purpose, instead we use the results of 9], which were shown by inspired by the recent progress in quantitative homogenization theory. The result of this section is used in the proof of Theorem 3.5.

The choice of $K=K(N)$ together with the second order term $F_{N}=\Phi_{n(N)}$ of $\psi_{t}$ and mesoscopic scaling parameters $n=n(N)$ and $\ell=\ell(N), 1 \ll n \ll \ell \ll N$, is given
in Section 5. We use the results in [9] for the convergence rate of the diffusion matrix approximated from the finite volume and shown uniformly in the density, and an $L^{\infty_{-}}$ estimate on the local function $\Phi_{n}$ with support size $n$, which is close to the optimizer of the variational formula (1.5) in $F$. The Schauder estimates for the solution of the hydrodynamic equation (1.11) are essentially used only in this section.

Sections 6, 7 and 8 are complementary and are devoted to the proofs of the Schauder estimates, the comparison theorem and the non-degeneracy of the diffusion matrix $D(\rho)$, respectively.

## 2 Proof of Theorem 1.1

To prove Theorem [1.1, we apply the relative entropy method as in [14] comparing the distribution of $\eta^{N}(t)$ with a properly taken local equilibrium state of second order approximation. Its leading term is determined from the solution $\rho_{K}(t, v)$ of the hydrodynamic equation (1.11). The second order term is determined by $F=F(\eta)$ which appears in the variational formula (1.5), and plays a similar role to the corrector in the theory of homogenization. Note that, for gradient models, the second order approximation is unnecessary; see [3], [10], [11].

Given a function $\lambda=\lambda(t, v) \in C^{1,3}\left([0, T] \times \mathbb{T}^{d}\right)$ and a function $F=F(\eta) \in \mathcal{F}_{0}^{d}$, we define a local equilibrium state $\psi_{t}(\eta) d \nu^{N}$ of second order approximation by

$$
\begin{align*}
\psi_{t}(\eta) & \equiv \psi_{\lambda(t, \cdot), F}(\eta)  \tag{2.1}\\
& =Z_{t}^{-1} \exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(t, x / N) \eta_{x}+\frac{1}{N} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, x / N), \tau_{x} F(\eta)\right)\right\}
\end{align*}
$$

for $\eta \in \mathcal{X}_{N}$, where $Z_{t}$ is the normalization constant with respect to $\nu^{N} \equiv \nu_{1 / 2}^{N}$ and $\partial \lambda \equiv \partial_{v} \lambda=\left\{\partial_{v_{i}} \lambda\right\}_{1 \leq i \leq d}$. We also write $\dot{\lambda}=\partial \lambda / \partial t, \partial^{2} \lambda \equiv \partial_{v}^{2} \lambda=\left\{\partial_{v_{i}} \partial_{v_{j}} \lambda\right\}_{1 \leq i, j \leq d}$ and $\partial^{3} \lambda \equiv \partial_{v}^{3} \lambda=\left\{\partial_{v_{i}} \partial_{v_{j}} \partial_{v_{k}} \lambda\right\}_{1 \leq i, j, k \leq d}$ for $\lambda=\lambda(t, v)$.

Denote by $f_{t}(\eta)=f_{t}^{N}(\eta)$ the density of the distribution of $\eta^{N}(t)$ on $\mathcal{X}_{N}$ with respect to $\nu^{N}$ and consider the relative entropy per volume defined by

$$
\begin{equation*}
h_{N}(t)=N^{-d} H\left(f_{t} \mid \psi_{t}\right) \tag{2.2}
\end{equation*}
$$

We will show that $h_{N}(t) \leq C N^{-\kappa}, t \in[0, T]$ with some $C=C_{T}>0$ and $\kappa>0$ by choosing $\lambda(t, \cdot)$ and $F$ in $\psi_{t}=\psi_{t}^{N}(\eta)$ properly as in the following proposition.
Proposition 2.1. Determine $\lambda(t, v) \equiv \lambda_{K}(t, v):=\bar{\lambda}(\rho(t, v))$ from the solution $\rho(t, v)=$ $\rho_{K}(t, v)$ of the hydrodynamic equation (1.11) with $K=K(N)$ and the initial value $\rho_{0}$ satisfying (1.12); recall (1.15) for $\bar{\lambda}(\rho)$. Suppose a sequence $K=K(N) \rightarrow \infty(N \rightarrow$ $\infty)$ is given and satisfies $1 \leq K \leq \bar{K}_{\delta}(N)=\delta \log N$. Let $\delta=\delta_{T}>0$ and functions $F_{N}=F_{N}(\eta) \in \mathcal{F}_{0}^{d}$ be chosen as in Section 5.2 below, namely, $\delta_{T}=\mathfrak{c} / T>0$ with sufficiently small $\mathfrak{c}>0$ and $F_{N}=\Phi_{n(N)}$ with $\Phi_{n}$ satisfying (5.10) and $n(N)=n^{a_{1}}$ where $a_{1} \in(0,1 /(2 d+5))$ is chosen sufficiently small. Consider $h_{N}(t)$ defined by (2.2) with $\psi_{t}=\psi_{\lambda(t, \cdot), F_{N}}$, and assume that $h_{N}(0) \leq C_{1} N^{-\kappa_{1}}$ for some $C_{1}>0$ and $\kappa_{1}>0$.

Then, there exist some $C=C_{T}>0$ and $\kappa>0$ such that $h_{N}(t) \leq C N^{-\kappa}$ holds for every $t \in[0, T]$.

The proof of Proposition 2.1 will be given in Section 3. We will calculate the time derivative of $h_{N}(t)$, in which derivatives of $\lambda_{K}(t, v)$ appear. For the solution $\rho=\rho_{K}(t, v)$ of the hydrodynamic equation (1.11) with smooth coefficients $D$ and $K f$, we have the Schauder estimates in terms of $K \geq 1$ :

$$
\begin{equation*}
\left\|\partial^{k} \rho\right\|_{\infty},\left\|\partial_{t} \rho\right\|_{\infty}\left\|\partial \partial_{t} \rho\right\|_{\infty} \leq C K^{\alpha_{0}}, \quad k=1,2,3 \tag{2.3}
\end{equation*}
$$

for some $\alpha_{0}>0$ and $C=C_{T}>0$, where $\|\cdot\|_{\infty}=\|\cdot\|_{L^{\infty}\left([0, T] \times \mathbb{T}^{d}\right)}$; see Section 6, In particular, for $\lambda=\lambda_{K}(t, v)=\bar{\lambda}\left(\rho_{K}(t, v)\right)$, recalling the definition (1.15) of $\bar{\lambda}$ and noting that $\rho_{K}(t, v)$ is uniformly away from 0 and 1 by Lemma 7.1 (the comparison theorem) below, we have

$$
\begin{equation*}
\|\partial \lambda\|_{3, \infty},\|\dot{\lambda}\|_{\infty},\|\partial \dot{\lambda}\|_{\infty} \leq C K^{\alpha_{0}} \tag{2.4}
\end{equation*}
$$

by changing $C=C_{T}>0$, where we set

$$
\|\partial \lambda\|_{3, \infty}:=\|\partial \lambda\|_{\infty}+\left\|\partial^{2} \lambda\right\|_{\infty}+\left\|\partial^{3} \lambda\right\|_{\infty}
$$

The Schauder estimates (2.3), (2.4) are actually used only in Section 5 except for (2.7) and Corollary 3.10 below. But, as these estimates suggest and also as $e^{K t / \delta_{*}}$ appears in (3.64) after applying Gronwall's inequality at the end of the proof in Section 3.7, at all steps in the proof of Proposition 2.1, we need to obtain error estimates that are strong enough to control diverging factors caused by $K$. This is useful to show the quantitative version of the hydrodynamic limit as well.

Note that, as the hydrodynamic equation, a discrete PDE was used in [3], [10], [11] to ensure an exact cancellation for the leading term in the entropy computation, but here we use a continuous PDE (1.11), since our error estimates are strong enough to cover the difference.

Proof of Theorem 1.1. Theorem 1.1 is deduced from Proposition 2.1 in the same way as in [3], [14], 30]. In fact, for every $\phi \in C^{\infty}\left(\mathbb{T}^{d}\right), \varepsilon>0$ and $t \in[0, T]$, consider a subset $\mathcal{A} \equiv \mathcal{A}_{N, \phi, \varepsilon, t}$ of $\mathcal{X}_{N}$ defined by

$$
\begin{equation*}
\mathcal{A}=\left\{\eta \in \mathcal{X}_{N} ;\left|\left\langle\rho^{N}(t), \phi\right\rangle-\left\langle\rho_{K}(t), \phi\right\rangle\right|>\varepsilon\right\} . \tag{2.5}
\end{equation*}
$$

Then, determining $\psi_{t}=\psi_{t}^{N}$ from $\lambda=\lambda_{K}$ and $F=F_{N}$ as in Proposition 2.1, since the assumption of Corollary 3.10 below is satisfied (in particular, the contribution of $F_{N}$ is negligible), the large deviation estimate holds for $\psi_{t} d \nu^{N}$ and thus we have

$$
\begin{equation*}
N^{-d} \log P^{\psi_{t}}(\mathcal{A}) \leq-C(\varepsilon) \tag{2.6}
\end{equation*}
$$

for some $C(\varepsilon)>0$ and every $N \in \mathbb{N}$. We will sometimes identify $\psi_{t}$ and $f_{t}$ with $\psi_{t} d \nu^{N}$ and $f_{t} d \nu^{N}$, denoted by $P^{\psi_{t}}$ and $P^{f_{t}}$, and the expectations under them by $E^{\psi_{t}}$ and $E^{f_{t}}$, respectively.

Note that the condition for the relative entropy at $t=0$ in Theorem 1.1 implies that for $h_{N}(0)$ in Proposition 2.1. Indeed, we have

$$
\begin{align*}
\left|H\left(f_{0} \mid \psi_{0}\right)-H\left(f_{0} \mid \widetilde{\psi}_{0}\right)\right| & =\left|\int f \log \left(\widetilde{\psi}_{0} / \psi_{0}\right) d \nu^{N}\right|  \tag{2.7}\\
& \leq C_{2} N^{d-1}\|\partial \lambda\|_{\infty}\left\|F_{N}\right\|_{\infty} \leq C_{3} N^{d-\kappa_{2}}
\end{align*}
$$

for some $\kappa_{2}>0$, by the Schauder estimates (2.4) and (5.10) noting that $F_{N}=\Phi_{n(N)}$ with $n(N)=N^{a_{1}}, a_{1}<1 /(2 d+5)$. Thus, the assumption $h_{N}(0) \leq C_{4} N^{-\kappa_{3}}$ of Proposition 2.1 (where $\kappa_{1}, C_{1}$ are replaced by $\kappa_{3}, C_{4}$ ) holds taking $\kappa_{3}=\kappa_{1} \wedge \kappa_{2}>0$, where $\kappa_{1}$ is the constant in Theorem 1.1.

Thus, by applying the entropy inequality and then by Proposition 2.1 and (2.6), we get

$$
P^{f_{t}}(\mathcal{A}) \leq \frac{\log 2+H\left(f_{t} \mid \psi_{t}\right)}{\log \left\{1+1 / P^{\psi_{t}}(\mathcal{A})\right\}} \leq \frac{\log 2+C N^{d-\kappa}}{\log \left\{1+e^{C(\varepsilon) N^{d}}\right\}} \leq C_{5} N^{-\kappa}
$$

This completes the proof of Theorem 1.1.
The goal is to show Proposition [2.1, that is, $h_{N}(t) \leq C N^{-\kappa}, t \in[0, T]$ for some $C=C_{T}>0$ and $\kappa>0$.

## 3 Proof of Proposition 2.1

### 3.1 Time derivative of the relative entropy

Let us begin with the following lemma in which we calculate the time derivative of $h_{N}(t)$. If we take $K=0$ (i.e. no Glauber part), this lemma coincides with Lemma 3.1 of [14], but the error estimate of order $o(1)$ given there is not sufficient for our purpose and we need to make it more precise.

For $\ell \in \mathbb{N}$ and $x \in \mathbb{T}_{N}^{d}\left(\right.$ or $\left.\mathbb{Z}^{d}\right)$, define

$$
\begin{equation*}
\Lambda_{\ell, x}:=\left\{y \in \mathbb{T}_{N}^{d}\left(\text { or } \mathbb{Z}^{d}\right) ;|y-x| \leq \ell\right\} \tag{3.1}
\end{equation*}
$$

and $\ell_{*}:=2 \ell+1$. Note that, in case of $\mathbb{T}_{N}^{d}$, by embedding it in $\mathbb{Z}^{d}$, the $\ell^{1}$-norm $|y-x|$ and therefore $\Lambda_{\ell, x}$ are well-defined at least if $\ell_{*}<N$. Note that $\left|\Lambda_{\ell, x}\right|=\ell_{*}^{d}$.

For $F=F(\eta) \equiv\left(F_{i}(\eta)\right)_{i=1}^{d} \in \mathcal{F}_{0}^{d}$, we set

$$
\begin{equation*}
\|F\|_{k, \infty}=r(F)^{d+k}\|F\|_{\infty}, \quad k=0,1,2 \tag{3.2}
\end{equation*}
$$

where $r(F)(\geq 1)$ denotes the radius (in $\ell^{1}$-sense, centered at 0 ) of the support of $F=F(\eta)$, that is,

$$
r(F)=\min \left\{r>0 ; \operatorname{supp} F \subset \Lambda_{r, 0}\right\}
$$

We use an abbreviation $\sum_{x, y}$ for $\sum_{x, y \in \mathbb{T}_{N}^{d}}:|x-y|=1$.

Lemma 3.1. Assume $\lambda \in C^{1,3}\left([0, T] \times \mathbb{T}^{d}\right)$ and $F \in \mathcal{F}_{0}^{d}$ for $\psi_{t}$ in (2.1). Then, setting $\rho(t, v):=\bar{\rho}(\lambda(t, v))$, we have

$$
\partial_{t} h_{N}(t) \leq E^{f_{t}}\left[\Omega_{1}+\Omega_{2}\right]+N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \dot{\lambda}(t, x / N) \rho(t, x / N)+Q_{N}^{E n}(\lambda, F)
$$

where $\Omega_{1}=\Omega_{1}(\eta)$ and $\Omega_{2}=\Omega_{2}(\eta)$ are defined respectively by

$$
\begin{aligned}
\Omega_{1}= & -\frac{N^{1-d}}{2} \sum_{x, y} c_{x, y} \Omega_{x, y} \\
\Omega_{2}= & -N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \dot{\lambda}(t, x / N) \eta_{x}+\frac{N^{-d}}{4} \sum_{x, y} c_{x, y} \Omega_{x, y}^{2} \\
& -\frac{N^{-d}}{4} \sum_{x, y} c_{x, y} \sum_{i, j} \partial_{v_{i}} \partial_{v_{j}} \lambda(t, x / N)\left(y_{i}-x_{i}\right)\left(y_{j}-x_{j}\right)\left(\eta_{y}-\eta_{x}\right) \\
& +\frac{N^{-d}}{2} \sum_{x, y} c_{x, y} \sum_{i, j} \partial_{v_{i}} \partial_{v_{j}} \lambda(t, x / N) \pi_{x, y}\left(\sum_{z \in \mathbb{T}_{N}^{d}}\left(z_{j}-x_{j}\right) \tau_{z} F_{i}\right) \\
& +N^{-d} K \sum_{x \in \mathbb{T}_{N}^{d}}\left\{\frac{c_{x}^{+}(\eta)}{\rho(t, x / N)}-\frac{c_{x}^{-}(\eta)}{1-\rho(t, x / N)}\right\}\left\{\eta_{x}-\rho(t, x / N)\right\}
\end{aligned}
$$

and

$$
\Omega_{x, y} \equiv \Omega_{x, y}(\eta)=\left(\partial \lambda(t, x / N),(y-x)\left(\eta_{y}-\eta_{x}\right)-\pi_{x, y}\left(\sum_{z \in \mathbb{T}_{N}^{d}} \tau_{z} F\right)\right)
$$

The error term $Q_{N}^{E n}(\lambda, F)$ has the estimate

$$
\begin{align*}
\left|Q_{N}^{E n}(\lambda, F)\right| \leq & C N^{-1}\left(1+\|\partial \lambda\|_{3, \infty}\right)^{3}\left(1+\|F\|_{2, \infty}\right)^{3}  \tag{3.3}\\
& +C N^{-1} K e^{\|\lambda\|_{\infty}}\|\partial \lambda\|_{\infty}\|F\|_{0, \infty} \\
& +C N^{-1}\|\partial \dot{\lambda}\|_{\infty}\|F\|_{\infty}+C N^{-1}\|\dot{\lambda}\|_{\infty}\|\partial \lambda\|_{\infty}\|F\|_{0, \infty}
\end{align*}
$$

as long as $\lambda$ and $F$ satisfy the bounds

$$
\begin{equation*}
N^{-1}\|\partial \lambda\|_{\infty} \leq 1, \quad N^{-1} r(F)^{d}\|\partial \lambda\|_{\infty}\|F\|_{\infty} \leq 1 \tag{3.4}
\end{equation*}
$$

(the constant 1 in the right-hand side may be replaced by any other constant).
Proof. We apply the estimate

$$
\begin{equation*}
\partial_{t} h_{N}(t) \leq N^{-d} \int \psi_{t}^{-1}\left(\mathcal{L}_{N}^{*} \psi_{t}-\partial_{t} \psi_{t}\right) \cdot f_{t} d \nu^{N} \tag{3.5}
\end{equation*}
$$

which holds for a large class of Markovian models, where $\mathcal{L}_{N}^{*}$ denotes the dual operator of the generator $\mathcal{L}_{N}$ with respect to the measure $\nu^{N}$; see [30] Lemma 1, [23] Lemma 3.1.

The term in the integrand on the right-hand side of (3.5) derived from the Kawasaki part was already computed in the proof of Lemma 3.1 of [14], but only with the error estimate $o(1)$. Let us record the computation (3.2) in [14] here to make the error term clear. Noting that $L_{K}^{*}=L_{K}$,

$$
\begin{align*}
& N^{-d} \psi_{t}^{-1} N^{2} L_{K} \psi_{t}  \tag{3.6}\\
= & \frac{N^{2-d}}{2} \sum_{x, y} c_{x, y}\left[\operatorname { e x p } \left\{(\lambda(t, x / N)-\lambda(t, y / N))\left(\eta_{y}-\eta_{x}\right)\right.\right. \\
& \left.\left.+\frac{1}{N} \pi_{x, y} \sum_{z \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, z / N), \tau_{z} F\right)\right\}-1\right] \\
= & -\frac{N^{1-d}}{2} \sum_{x, y} c_{x, y} \Omega_{x, y}+\frac{N^{-d}}{4} \sum_{x, y} c_{x, y} \Omega_{x, y}^{2} \\
& -\frac{N^{-d}}{4} \sum_{x, y} c_{x, y} \sum_{i, j} \partial_{v_{i}} \partial_{v_{j}} \lambda(t, x / N)\left(y_{i}-x_{i}\right)\left(y_{j}-x_{j}\right)\left(\eta_{y}-\eta_{x}\right) \\
& +\frac{N^{-d}}{2} \sum_{x, y} c_{x, y} \sum_{i, j} \partial_{v_{i}} \partial_{v_{j}} \lambda(t, x / N) \pi_{x, y}\left(\sum_{z \in \mathbb{T}_{N}^{d}}\left(z_{j}-x_{j}\right) \tau_{z} F_{i}\right)+Q_{1, N},
\end{align*}
$$

where the error term $Q_{1, N} \equiv Q_{1, N}(\lambda, F)$ can be estimated as

$$
\begin{equation*}
\left|Q_{1, N}\right| \leq C N^{-1}\left(1+\|\partial \lambda\|_{3, \infty}\right)^{3}\left(1+\| \| F \|_{2, \infty}\right)^{3} \tag{3.7}
\end{equation*}
$$

if the condition (3.4) and accordingly $\left|\varepsilon_{N}\right| \leq C$ below are satisfied for some $C>0$.
Indeed, to show (3.7), we expand the second to the third lines of (3.6) as

$$
\exp \left\{\varepsilon_{N}\right\}-1=\varepsilon_{N}+\frac{1}{2} \varepsilon_{N}^{2}+O\left(\varepsilon_{N}^{3}\right), \quad\left|\varepsilon_{N}\right| \leq C
$$

for $\varepsilon_{N} \equiv \varepsilon_{N, x, y}$ given in the braces. Then, by Taylor's formula, we have

$$
\begin{aligned}
\lambda(t, x / N)-\lambda(t, y / N)=- & \frac{1}{N}(\partial \lambda(t, x / N),(y-x)) \\
& -\frac{1}{2 N^{2}}(y-x) \cdot \partial^{2} \lambda(t, x / N)(y-x)+O\left(N^{-3}\left\|\partial^{3} \lambda\right\|_{\infty}\right),
\end{aligned}
$$

and therefore

$$
\varepsilon_{N}=-\frac{1}{N} \Omega_{x y}+\frac{1}{N} \bar{\Omega}_{x y}-\frac{1}{2 N^{2}}(y-x) \cdot \partial^{2} \lambda(t, x / N)(y-x)\left(\eta_{y}-\eta_{x}\right)+O\left(N^{-3}\left\|\partial^{3} \lambda\right\|_{\infty}\right),
$$

where

$$
\begin{aligned}
& \bar{\Omega}_{x, y} \equiv \bar{\Omega}_{x, y}(\eta)=\pi_{x, y} \sum_{z \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, z / N)-\partial \lambda(t, x / N), \tau_{z} F\right) \\
& =N^{-1}\left(\partial^{2} \lambda(t, x / N) \pi_{x, y} \sum_{z \in \mathbb{T}_{N}^{d}}(z-x), \tau_{z} F\right)+O\left(N^{-2}\left\|\partial^{3} \lambda\right\|_{\infty}\left|\pi_{x y} \sum_{z \in \mathbb{T}_{N}^{d}}(z-x)^{\otimes 2}, \tau_{z} F\right|\right) .
\end{aligned}
$$

Thus, $Q_{1, N} \equiv Q_{1, N}(\lambda, F)$ is given by

$$
\begin{aligned}
Q_{1, N}= & \frac{N^{2-d}}{2} \sum_{x, y} c_{x, y} O\left(N^{-3}\left\|\partial^{3} \lambda\right\|_{\infty}\left(1+\|F\|_{2, \infty}\right)\right) \\
& +\frac{N^{2-d}}{4} \sum_{x, y} c_{x, y}\left(\varepsilon_{N}^{2}-N^{-2} \Omega_{x, y}^{2}\right)+O\left(N^{2-d} \sum_{x, y} c_{x, y} \varepsilon_{N}^{3}\right)
\end{aligned}
$$

The first term is $O\left(N^{-1}\left\|\partial^{3} \lambda\right\|_{\infty}\left(1+\|F\|_{2, \infty}\right)\right)$. By noting that $\left|\Omega_{x y}\right| \leq\|\partial \lambda\|_{\infty}(1+$ $\left.\|F\|_{0, \infty}\right)$, the second is bounded by

$$
\begin{aligned}
& \left|\frac{N^{2-d}}{4} \sum_{x, y} c_{x, y}\left(\varepsilon_{N}+\frac{1}{N} \Omega_{x, y}\right)\left(\varepsilon_{N}-\frac{1}{N} \Omega_{x, y}\right)\right| \\
& \leq C N^{2}\left(\frac{1}{N^{2}}\left\|\partial^{2} \lambda\right\|_{\infty}\|F F\|_{1, \infty}+\frac{1}{N^{3}}\left\|\partial^{3} \lambda\right\|_{\infty}\|F\|_{2, \infty}+\frac{1}{N^{2}}\left\|\partial^{2} \lambda\right\|_{\infty}+\frac{1}{N^{3}}\left\|\partial^{3} \lambda\right\|_{\infty}\right) \\
& \quad \times\left(\frac{2}{N}\|\partial \lambda\|_{\infty}\left(1+\| \| F \|_{0, \infty}\right)+\frac{1}{N^{2}}\left\|\partial^{2} \lambda\right\|_{\infty}\|F\|_{1, \infty}\right. \\
& \left.\quad \quad+\frac{1}{N^{3}}\left\|\partial^{3} \lambda\right\|_{\infty}\|F F\|_{2, \infty}+\frac{1}{N^{2}}\left\|\partial^{2} \lambda\right\|_{\infty}+\frac{1}{N^{3}}\left\|\partial^{3} \lambda\right\|_{\infty}\right) \\
& \leq C N^{-1}\left(1+\|\partial \lambda\|_{3, \infty}\right)^{2}\left(1+\|F\|_{2, \infty}\right)^{2} .
\end{aligned}
$$

Similarly, the third is bounded by

$$
\begin{aligned}
& C N^{2}\left\{\frac{1}{N^{3}} \sup _{x, y}\left|\Omega_{x y}\right|^{3}+\left(\frac{1}{N^{2}}\left\|\partial^{2} \lambda\right\|_{\infty}\|F\|_{1, \infty}+\frac{1}{N^{3}}\left\|\partial^{3} \lambda\right\|_{\infty}\|F F\|_{2, \infty}\right)^{3}\right. \\
&\left.\quad+\left(\frac{1}{N^{2}}\left\|\partial^{2} \lambda\right\|_{\infty}\right)^{3}+\left(\frac{1}{N^{3}}\left\|\partial^{3} \lambda\right\|_{\infty}\right)^{3}\right\} \\
& \leq C N^{-1}\left(1+\|\partial \lambda\|_{3, \infty}\right)^{3}\left(1+\|\mid F\|_{2, \infty}\right)^{3} .
\end{aligned}
$$

Summarizing these estimates for three terms of $Q_{1, N}(\lambda, F)$, we obtain (3.7) for $Q_{1, N}(\lambda, F)$.
Next, we compute the contribution from the Glauber part. First we note that the dual operator $L_{G}^{*}$ of $L_{G}$ with respect to $\nu^{N}$ is given by

$$
L_{G}^{*} g(\eta)=\sum_{x \in \mathbb{T}_{N}^{d}}\left\{c_{x}\left(\eta^{x}\right) g\left(\eta^{x}\right)-c_{x}(\eta) g(\eta)\right\}
$$

Therefore, we have

$$
\begin{align*}
& N^{-d} K \psi_{t}^{-1} L_{G}^{*} \psi_{t}  \tag{3.8}\\
&= N^{-d} K \sum_{x \in \mathbb{T}_{N}^{d}}\left[c_{x}\left(\eta^{x}\right) \exp \left\{\pi_{x}\left(\sum_{z} \lambda(t, z / N) \eta_{z}+\frac{1}{N} \sum_{z \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, z / N), \tau_{z} F(\eta)\right)\right)\right\}-c_{x}(\eta)\right]
\end{align*}
$$

$=N^{-d} K \sum_{x \in \mathbb{T}_{N}^{d}}\left[c_{x}\left(\eta^{x}\right) \exp \left\{\lambda(t, x / N)\left(1-2 \eta_{x}\right)+\frac{1}{N} \sum_{z \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, z / N), \pi_{x} \tau_{z} F(\eta)\right)\right\}-c_{x}(\eta)\right]$
$=N^{-d} K \sum_{x \in \mathbb{T}_{N}^{d}}\left[c_{x}\left(\eta^{x}\right) \exp \left\{\lambda(t, x / N)\left(1-2 \eta_{x}\right)\right\}-c_{x}(\eta)\right]+Q_{2, N}$,
However, the leading term can be rewritten as the fifth term of $\Omega_{2}$ noting (1.3) and (1.14). Indeed, writing $\lambda=\lambda(t, x / N), \rho=\rho(t, x / N)$ and $c_{x}^{ \pm}=c_{x}^{ \pm}(\eta)$ for simplicity, the term inside the brackets in the last sum is rewritten as

$$
\left(c_{x}^{+} e^{-\lambda} 1_{\left\{\eta_{x}=1\right\}}+c_{x}^{-} e^{\lambda} 1_{\left\{\eta_{x}=0\right\}}\right)-\left(c_{x}^{+} 1_{\left\{\eta_{x}=0\right\}}+c_{x}^{-} 1_{\left\{\eta_{x}=1\right\}}\right) .
$$

Then, we may use $e^{-\lambda}=(1-\rho) / \rho, e^{\lambda}=\rho /(1-\rho), 1_{\left\{\eta_{x}=1\right\}}=\left(\eta_{x}-\rho\right)+\rho$ and $1_{\left\{\eta_{x}=0\right\}}=$ $(1-\rho)-\left(\eta_{x}-\rho\right)$; see Lemma 2.3 of [10].

The error term $Q_{2, N} \equiv Q_{2, N}(\lambda, F)$ in (3.8) can be estimated as

$$
\begin{equation*}
\left|Q_{2, N}\right| \leq C N^{-1} K e^{\|\lambda\|_{\infty}}\|\partial \lambda\|_{\infty}\|F\|_{0, \infty}, \tag{3.9}
\end{equation*}
$$

if the second bound in the condition (3.4) is satisfied. Indeed,

$$
\exp \left\{\varepsilon_{N}\right\}=1+O\left(\varepsilon_{N}\right), \quad\left|\varepsilon_{N}\right| \leq C
$$

for $\varepsilon_{N} \equiv \varepsilon_{N, x}=\frac{1}{N} \sum_{z \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, z / N), \pi_{x} \tau_{z} F(\eta)\right)$. Thus,

$$
\begin{aligned}
Q_{2, N}=N^{-d} K \sum_{x \in \mathbb{T}_{N}^{d}} c_{x}\left(\eta^{x}\right) & \exp \left\{\lambda(t, x / N)\left(1-2 \eta_{x}\right)\right\} \\
& \times O\left(\frac{1}{N} \sum_{z \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, z / N), \pi_{x} \tau_{z} F(\eta)\right)\right)
\end{aligned}
$$

and therefore we obtain (3.9).
Finally, in (3.5),

$$
\begin{align*}
N^{-d} \psi_{t}^{-1} \partial_{t} \psi_{t}= & -N^{-d} Z_{t}^{-1} \partial_{t} Z_{t}  \tag{3.10}\\
& +N^{-d} \partial_{t}\left\{\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(t, x / N) \eta_{x}+\frac{1}{N} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, x / N), \tau_{x} F\right)\right\} .
\end{align*}
$$

From (3.6), (3.8) and (3.10), it follows that

$$
\begin{equation*}
N^{-d} \psi_{t}^{-1}\left(\mathcal{L}_{N}^{*} \psi_{t}-\partial_{t} \psi_{t}\right)=\Omega_{1}(\eta)+\Omega_{2}(\eta)+a(t)+\sum_{i=1}^{3} Q_{i, N} \tag{3.11}
\end{equation*}
$$

where

$$
Q_{3, N} \equiv Q_{3, N}(\lambda, F)=-N^{-d-1} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \dot{\lambda}(t, x / N), \tau_{x} F\right),
$$

and

$$
\begin{equation*}
a(t):=N^{-d} Z_{t}^{-1} \partial_{t} Z_{t}=E^{\psi_{t}}\left[N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \dot{\lambda}(t, x / N) \eta_{x}\right]+O\left(N^{-1}\|\partial \dot{\lambda}\|_{\infty}\|F\|_{\infty}\right) \tag{3.12}
\end{equation*}
$$

The last equality for $a(t)$ is seen from (3.10) by noting that

$$
E^{\psi_{t}}\left[N^{-d} \psi_{t}^{-1} \partial_{t} \psi_{t}\right]=0
$$

and

$$
\begin{equation*}
\left|Q_{3, N}\right| \leq N^{-1}\|\partial \dot{\lambda}\|_{\infty}\|F\|_{\infty} \tag{3.13}
\end{equation*}
$$

Thus,

$$
a(t)=N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \dot{\lambda}(t, x / N) \rho(t, x / N)+Q_{4, N}+O\left(N^{-1}\|\partial \dot{\lambda}\|_{\infty}\|F\|_{\infty}\right),
$$

where the error $Q_{4, N} \equiv Q_{4, N}(\lambda, F)$ is given by

$$
Q_{4, N}=N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \dot{\lambda}(t, x / N)\left(E^{\psi_{t}}\left[\eta_{x}\right]-\rho(t, x / N)\right) .
$$

We only need to estimate $\left|E^{\psi_{t}}\left[\eta_{x}\right]-\rho(t, x / N)\right|$.
To give an estimate for $Q_{4, N} \equiv Q_{4, N}(\lambda, F)$, we note the $r$-Markov property of $\psi_{t}$ (or $P^{\psi_{t}}$ ). In the next lemma, we denote $\psi_{t}$ by $\psi$ for simplicity by omitting $t$ and $\frac{1}{N}$ in front of the sum involving $F$. For $\Lambda \subset \mathbb{T}_{N}^{d}$ and $r \in \mathbb{N}$, set $\partial_{r} \Lambda=\left\{y \in \mathbb{T}_{N}^{d} \backslash \Lambda ; \operatorname{dist}(y, \Lambda) \leq r\right\}$, $\bar{\Lambda}=\Lambda \cup \partial_{r} \Lambda$, where $\operatorname{dist}(y, \Lambda)=\min \{|x-y| ; x \in \Lambda\}$ is defined in the $\ell^{1}$-sense. We consider $\Lambda$ with a sufficiently small radius so that $\operatorname{dist}(y, \Lambda)$ is well defined; actually we take $\Lambda=\{x\}$ in (3.18) later. For $\eta \in\{0,1\}^{\Lambda}$ and $\omega \in\{0,1\}^{\partial_{r} \Lambda}, \eta \cdot \omega \in\{0,1\}^{\bar{\Lambda}}$ is defined by $(\eta \cdot \omega)_{x}=\eta_{x}$ for $x \in \Lambda$ and $=\omega_{x}$ for $x \in \partial_{r} \Lambda$. Define

$$
\begin{aligned}
& H_{\bar{\Lambda}}(\eta \cdot \omega):=\sum_{y \in \bar{\Lambda}} \lambda(y / N)(\eta \cdot \omega)_{y}+\sum_{y \in \mathbb{T}_{N}^{d}: \operatorname{supp} \tau_{y} F \subset \bar{\Lambda}}\left(\partial \lambda(y / N), \tau_{y} F(\eta \cdot \omega)\right), \\
& P_{\Lambda}^{\omega}(\eta):=Z_{\omega}^{-1} e^{H_{\bar{\Lambda}}(\eta \cdot \omega)}, \quad Z_{\omega}:=\sum_{\eta \in\{0,1\}^{\Lambda}} e^{H_{\bar{\Lambda}}(\eta \cdot \omega)} .
\end{aligned}
$$

Lemma 3.2. Let $F \in \mathcal{F}_{0}^{d}$ and $r=r(F)$. Then, $\psi$ has an $r$-Markov property, that is, for $\Lambda \subset \mathbb{T}_{N}^{d}$ and $\eta \in\{0,1\}^{\Lambda}$,

$$
\begin{equation*}
P^{\psi}\left([\eta] \mid \mathcal{F}_{\Lambda^{c}}\right)(\omega)=P_{\Lambda}^{\bar{\omega}}(\eta), \quad P^{\psi} \text {-a.s. } \omega \tag{3.14}
\end{equation*}
$$

holds, where $[\eta]=\left\{\zeta \in\{0,1\}^{\mathbb{T}_{N}^{d}} ;\left.\zeta\right|_{\Lambda}=\eta\right\}$ and $\bar{\omega}=\left.\omega\right|_{\partial_{r} \Lambda}$. Recall $P^{\psi}=\psi d \nu^{N}$.
Proof. The lemma is well-known and the proof is elementary, but we give it for completeness. Since the right-hand side of (3.14) is $\mathcal{F}_{\Lambda^{c}-\text {-measurable in } \omega \text {, it is enough to }}$ show

$$
\begin{equation*}
E^{\psi}[f(\eta) g(\omega)]=E^{\psi}\left[g(\omega) E^{P_{\Lambda}^{\bar{\omega}}}[f]\right] \tag{3.15}
\end{equation*}
$$

for every $\mathcal{F}_{\Lambda}$-measurable function $f$ and $\mathcal{F}_{\Lambda^{c}}$-measurable function $g$. The left-hand side of (3.15) is given by

$$
\begin{equation*}
Z^{-1} \sum_{\eta \in\{0,1\}^{\wedge}, \omega \in\{0,1\}^{\Lambda^{c}}} f(\eta) g(\omega) e^{H_{N}(\eta \cdot \omega)} \tag{3.16}
\end{equation*}
$$

while the right-hand side is rewritten as

$$
\begin{equation*}
Z^{-1} \sum_{\eta \in\{0,1\}^{\Lambda}, \omega \in\{0,1\}^{\wedge}} g(\omega) e^{H_{N}(\eta \cdot \omega)} Z_{\bar{\omega}}^{-1} \sum_{\zeta \in\{0,1\}^{\Lambda}} f(\zeta) e^{H_{\bar{\Lambda}}(\zeta \cdot \bar{\omega})}, \tag{3.17}
\end{equation*}
$$

where $Z$ is a normalization constant (including the factor $\nu^{N}(\eta \cdot \omega) \equiv 2^{-N}$ ), and

$$
\begin{aligned}
H_{N}(\eta \cdot \omega): & =\sum_{y \in \mathbb{T}_{N}^{d}} \lambda(y / N)(\eta \cdot \omega)_{y}+\sum_{y \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(y / N), \tau_{y} F(\eta \cdot \omega)\right) \\
& =H_{\bar{\Lambda}}(\eta \cdot \bar{\omega})+\widetilde{H}_{\bar{\Lambda}^{c}}(\eta \cdot \omega),
\end{aligned}
$$

with $H_{\bar{\Lambda}}(\eta \cdot \bar{\omega})$ defined above and

$$
\widetilde{H}_{\bar{\Lambda}^{c}}(\eta \cdot \omega)=\sum_{y \in \bar{\Lambda}^{c}} \lambda(y / N)(\eta \cdot \omega)_{y}+\sum_{y \in \mathbb{T}_{N}^{d}: \operatorname{supp} \tau_{y} F \cap \bar{\Lambda}^{c} \neq \emptyset}\left(\partial \lambda(y / N), \tau_{y} F(\eta \cdot \omega)\right)
$$

However, $(\eta \cdot \omega)_{y}=\omega_{y}$ for $y \in \bar{\Lambda}^{c}$ in the first sum and $\tau_{y} F(\eta \cdot \omega)=\tau_{y} F(\omega)$ for $y \in \mathbb{T}_{N}^{d}$ such that $\operatorname{supp} \tau_{y} F \cap \bar{\Lambda}^{c} \neq \emptyset$ in the second sum, since the radius of the support of $F$ is $r$ so that $\operatorname{supp} \tau_{y} F \cap \Lambda=\emptyset$. Thus, $\widetilde{H}_{\bar{\Lambda} c}(\eta \cdot \omega) \equiv \widetilde{H}_{\bar{\Lambda}^{c}}(\omega)$ is a function of $\omega$ only. Therefore, in (3.17),

$$
\sum_{\eta \in\{0,1\}^{\Lambda}} e^{H_{N}(\eta \cdot \omega)}=Z_{\bar{\omega}} \cdot e^{\widetilde{H}_{\bar{\Lambda} c}(\omega)} .
$$

Accordingly, the right-hand side is equal to

$$
Z^{-1} \sum_{\omega \in\{0,1\}^{\Lambda^{c}}} g(\omega) \sum_{\zeta \in\{0,1\}^{\Lambda}} f(\zeta) e^{H_{\bar{\Lambda}}(\zeta \cdot \bar{\omega})} e^{\widetilde{H}_{\bar{\Lambda} c}(\omega)},
$$

which coincides with (3.16), that is the left-hand side of (3.15). This completes the proof of the lemma.

We now return to the estimate for $Q_{4, N} \equiv Q_{4, N}(\lambda, F)$. Taking $\Lambda=\{x\}, r=r(F)$ and $\bar{\Lambda}=\Lambda_{r(F), x}$ in Lemma 3.2, we see

$$
\begin{equation*}
E^{\psi_{t}}\left[\eta_{x}\right]=E^{\psi_{t}}\left[E^{P_{\{x\}}^{\omega, F}}\left[\eta_{x}\right]\right] \tag{3.18}
\end{equation*}
$$

and

$$
\begin{align*}
E^{P_{x x\}}^{\omega, F}}\left[\eta_{x}\right] & :=\widetilde{Z}_{\omega, F}^{-1} \sum_{\eta_{x} \in\{0,1\}} \eta_{x} e^{\lambda(t, x / N) \eta_{x}+\frac{1}{N} \sum_{y \in \mathbb{T}_{N}^{d}: \operatorname{supp} \tau_{y} F \subset \bar{\Lambda}}\left(\partial \lambda(t, y / N), \tau_{y} F\left(\eta_{x} \cdot \omega\right)\right)}  \tag{3.19}\\
& =: \widetilde{Z}_{\omega, F}^{-1} A_{\omega, F}
\end{align*}
$$

for $\omega \in\{0,1\}^{\bar{\Lambda} \backslash\{x\}}$, where

$$
\begin{equation*}
\widetilde{Z}_{\omega, F}:=\sum_{\eta_{x} \in\{0,1\}} e^{\lambda(t, x / N) \eta_{x}+\frac{1}{N} \sum_{y \in \mathbb{T}_{N}^{d}}: \operatorname{supp} \tau_{y} F \subset \bar{\Lambda}}\left(\partial \lambda(t, y / N), \tau_{y} F\left(\eta_{x} \cdot \omega\right)\right) . \tag{3.20}
\end{equation*}
$$

Note that $\sum_{y \in \bar{\Lambda} \backslash\{x\}} \lambda(y / N) \omega_{y}$ in $H_{\bar{\Lambda}}(\eta \cdot \omega)$ cancels with that in $Z_{\omega}$ and gives the formula (3.19) with $\widetilde{Z}_{\omega, F}$ determined by (3.20).

Noting that $E^{P_{\{x\}}^{\omega, 0}}\left[\eta_{x}\right]=\rho(t, x / N)$ taking $F \equiv 0$, we have

$$
E^{P_{\{x\}}^{\omega, F}}\left[\eta_{x}\right]-\rho(t, x / N)=\widetilde{Z}_{\omega, F}^{-1} A_{\omega, F}-\widetilde{Z}_{\omega, 0}^{-1} A_{\omega, 0}
$$

A simple estimate shows

$$
\begin{aligned}
& \widetilde{Z}_{0} e^{-\frac{c}{N} r(F)^{d}\|\partial \lambda(t,)\|_{\infty}\|F\|_{\infty}} \leq \widetilde{Z}_{\omega, F} \leq \widetilde{Z}_{0} e^{\frac{c}{N} r(F)^{d}\|\partial \lambda(t,)\|_{\infty}\|F\|_{\infty}},
\end{aligned}
$$

for $A_{0}=A_{\omega, 0}, \widetilde{Z}_{0}=\widetilde{Z}_{\omega, 0}$ and some $c>0$. Therefore, taking the expectation in $\omega$ under $P^{\psi_{t}}$, we obtain by (3.18)

$$
\begin{aligned}
\left|E^{\psi_{t}}\left[\eta_{x}\right]-\rho(t, x / N)\right| & =\left|E^{\psi_{t}}\left[\frac{A_{0}}{\widetilde{Z}_{\omega, F}}\left(\frac{A_{\omega, F}}{A_{0}}-\frac{\widetilde{Z}_{\omega, F}}{\widetilde{Z}_{0}}\right)\right]\right| \\
& \leq C_{1} \left\lvert\, e^{\left.\frac{c}{N} r(F)^{d}\|\partial \lambda(t, \cdot)\|_{\infty}\|F\|_{\infty}-1 \right\rvert\,}\right. \\
& \leq C_{2} N^{-1} r(F)^{d}\|\partial \lambda\|_{\infty}\|F\|_{\infty}
\end{aligned}
$$

if $F$ satisfies the condition (3.4): $N^{-1} r(F)^{d}\|\partial \lambda\|_{\infty}\|F\|_{\infty} \leq 1$; note that $0 \leq A_{0} / \widetilde{Z}_{\omega, F}=$ $A_{0} / \widetilde{Z}_{0} \cdot \widetilde{Z}_{0} / \widetilde{Z}_{\omega, F} \leq e^{c}$ under this condition. This leads to the bound on $Q_{4, N} \equiv Q_{4, N}(\lambda, F)$ :

$$
\begin{equation*}
\left|Q_{4, N}\right| \leq C N^{-1}\|\dot{\lambda}\|_{\infty}\|\partial \lambda\|_{\infty}\|F\|_{0, \infty} \tag{3.21}
\end{equation*}
$$

By (3.7), (3.9), (3.13) and (3.21), we obtain (3.3), and this concludes the proof of Lemma 3.1

### 3.2 Refined one-block estimate

We now show the one-block estimate, that is, the error estimate for the replacement of the microscopic function $\Omega_{2}$ of order $O(1)$ (first four terms) and $O(K)$ (last term) by its ensemble average with mean $\rho=\bar{\eta}_{x}^{\ell}$ (see (3.22) below) under the integral with respect to $P^{f_{t}}$ and also in $t \in[0, T]$. As we pointed in Section 2, we need to prepare an error estimate strong enough for later use. The classical one-block estimate can be shown even with the diverging Glauber part as discussed in Remark 3.1 below, but it is not sufficient for our purpose.

Indeed, we will show a refined one-block estimate in Theorem 3.3 below in a similar manner to Theorem 1.4 of [10], but, differently from it, we don't need the relative entropy on the right-hand side of the estimate (3.25).

For $h \in \mathcal{F}_{0}$, set

$$
f_{x}(\eta) \equiv f_{x}^{\ell}(\eta)=\tau_{x} h(\eta)-\langle h\rangle\left(\bar{\eta}_{x}^{\ell}\right)
$$

where we denote $\langle\cdot\rangle(\rho)$ for $\langle\cdot\rangle_{\rho}, \rho \in[0,1]$. Define a local sample average of $\eta$ over $\Lambda_{\ell, x}$

$$
\begin{equation*}
\bar{\eta}_{x}^{\ell} \equiv \bar{\eta}_{\Lambda_{\ell, x}}:=\ell_{*}^{-d} \sum_{y \in \Lambda_{\ell, x}} \eta_{y} \tag{3.22}
\end{equation*}
$$

recall (3.1) for $\Lambda_{\ell, x}$ and $\ell_{*}(<N)$.
Theorem 3.3. Let $a_{t, x}, t \in[0, T]$ and $x \in \mathbb{T}_{N}^{d}$, be deterministic coefficients which satisfy

$$
\begin{equation*}
\left|a_{t, x}\right| \leq M \quad \text { for all } t \in[0, T] \text { and } x \in \mathbb{T}_{N}^{d} \tag{3.23}
\end{equation*}
$$

We assume

$$
\begin{equation*}
K^{3 / 2} \ell_{*}^{(d+2) / 2} \leq \delta N \tag{3.24}
\end{equation*}
$$

for some $\delta>0$ small enough (see Lemma 3.4 below for the choice of $\delta$ ) and for all $N$ large enough. Then, there exists $C>0$ such that for all $N$ large enough,

$$
\begin{align*}
& E\left[\left|\int_{0}^{T} N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} a_{t, x} f_{x}\left(\eta^{N}(t)\right) d t\right|\right]  \tag{3.25}\\
& \quad \leq C\left(M\|h\|_{\infty}+1\right)\left(N^{-1} K^{1 / 2} \ell^{(d+2) / 2}+\ell^{-d} r(h)^{d}\right)
\end{align*}
$$

Recall that $r(h)$ denotes the radius of the support of $h$.
We will apply this theorem for $\Omega_{2}$ in the proof of Lemma 3.8 later.
Proof. We follow the argument in Section 3 of [10], where the same Glauber-Kawasaki dynamics $\eta^{N}(t)$ was considered. Note that although the gradient condition was assumed in [10], it was not used in Section 3. We first decompose as

$$
\begin{align*}
E\left[\left|\int_{0}^{T} N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} a_{t, x} f_{x} d t\right|\right] \leq & \leq\left[\left|\int_{0}^{T} N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} a_{t, x} m_{x} d t\right|\right]  \tag{3.26}\\
& +E\left[\left|\int_{0}^{T} N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} a_{t, x} E^{\nu_{1 / 2}}\left[f_{x} \mid \bar{\eta}_{x}^{\ell}\right] d t\right|\right]
\end{align*}
$$

see (3.1) of [10], where $\nu_{1 / 2}$ is the Bernoulli measure with $\rho=1 / 2$ on $\mathcal{X}$ and

$$
m_{x}:=f_{x}-E^{\nu_{1 / 2}}\left[f_{x} \mid \bar{\eta}_{x}^{\ell}\right] .
$$

Then, for the first term in (3.26), Lemma 3.1 of [10] holds; we take $\Theta=0, \theta=1, \varepsilon(N) \downarrow 0$ (so that $\varepsilon^{1-\Theta}=0, \varepsilon^{2 \Theta}=1$ ) and get the next Lemma 3.4. Note that the proof is the same, except that at the last point we estimate

$$
\sup _{t, x, \eta}\left|a_{t, x} m_{x}\right|^{2} \leq(2 M)^{2}\|h\|_{\infty}^{2}
$$

Lemma 3.4. Let $\gamma=\gamma(N)>0$. If $\gamma K \ell_{*}^{d+2} \leq \delta N^{2}$ for some $\delta>0$ small enough, then for all $N$ large enough

$$
E\left[\left|\int_{0}^{T} N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} a_{t, x} m_{x} d t\right|\right] \leq C\left(\frac{K}{\gamma}+\frac{\gamma \ell_{*}^{d+2}}{N^{2}} M^{2}\|h\|_{\infty}^{2}\right),
$$

for some $C>0$. In particular, choosing $\gamma=N K^{1 / 2} \ell_{*}^{-(d+2) / 2} /\left(M\|h\|_{\infty}+1\right)$, the right-hand side is bounded by

$$
2 C N^{-1} K^{1 / 2} \ell_{*}^{(d+2) / 2}\left(M\|h\|_{\infty}+1\right)
$$

For this choice of $\gamma$, the above condition for $\gamma$ is satisfied if (3.24) stated above holds.
Note that the condition ' $\gamma K \ell_{*}^{d+2} \leq \delta N^{2}$ for some $\delta>0$ small enough' was used for the denominator in (3.10) of [10] (with $\theta=1, \varepsilon^{-\Theta}=1$ ), derived by Rayleigh estimate, to stay uniformly positive, say $\geq 1 / 2$. This determines how small $\delta>0$ needs to be.

Next, by Theorem 4.1 of [2] which provides the equivalence of ensembles for general Gibbs measures with precise convergence speed (cf. Lemma 3.2 of [10), we have the following estimate. There exists $C>0$ such that for all $N$ sufficiently large

$$
\begin{equation*}
\sup _{\rho \in[0,1]} \max _{x \in \mathbb{T}_{N}^{d}} \sup _{\eta \in \mathcal{X}_{N}}\left|E^{\nu_{\rho}}\left[\tau_{x} h \mid \bar{\eta}_{x}^{\ell}\right]-\langle h\rangle\left(\bar{\eta}_{x}^{\ell}\right)\right| \leq \frac{C}{\ell^{d}}|\Delta|\|h\|_{\infty} \tag{3.27}
\end{equation*}
$$

where the local function $h$ has a support in $\Delta$ such that $|\Delta| \leq \ell^{d(1-\delta)}$. Note that one may take $h$ for $f_{x}$ in Lemma 3.2 of [10]. Combining the two estimates given in Lemma 3.4 and (3.27), the proof of Theorem 3.3 is concluded.

Remark 3.1. In the estimate (4.10) of [8], taking $\nu_{t} \equiv \nu^{N}\left(=\nu_{1 / 2}^{N}\right)$, the second term on the right-hand side vanishes and also, in the first term $-\mathcal{D}\left(\sqrt{f_{t}} ; \nu^{N}\right)$, one can drop the contribution of the Glauber part (note that this term is not really the Dirichlet form associated with the Glauber generator in the sense that $\nu^{N}$ is not in general a reversible measure of the Glauber part), since it is non-positive in view of (4.9) of [8]. Since a classical one-block estimate (and also two-blocks estimate) was shown relying only on the estimate obtained in this way, we have the same result as Theorem 2.7 of [8] or Theorem 3.1 of [14] even with a diverging Glauber part in our generator $\mathcal{L}_{N}$. In other words, one can show that the expectation in (3.25) with $a_{t, x} \equiv 1$ tends to 0 as $N \rightarrow \infty$ and then $\ell \rightarrow \infty$. But, this is not enough for our purpose.

### 3.3 Boltzmann-Gibbs principle for gradient replacement

For the microscopic function $\Omega_{1}$ which is given in Lemma 3.1] and looks $O(N)$, we need the following Boltzmann-Gibbs principle for the gradient replacement. This is a refinement of Theorem 3.2 of [14] adding the Glauber part and giving the necessary error estimates.

Theorem 3.5. There exists $C>0$ such that

$$
\int_{0}^{T} E^{f_{t}}\left[\Omega_{1}+N^{1-d} \sum_{x \in \mathbb{T}_{N}^{d}}\left(D\left(\bar{\eta}_{x}^{\ell}\right) \partial \lambda(t, x / N), \ell_{*}^{-d} \tau_{x} A_{\ell}\right)\right.
$$

$$
\begin{aligned}
& \left.\quad-\frac{\beta N^{-d}}{2} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, x / N), R\left(\bar{\eta}_{x}^{\ell} ; F\right) \partial \lambda(t, x / N)\right)\right] d t \\
& \leq \frac{C}{\beta} K+\beta^{2} Q_{N, \ell}^{(1)}(\lambda, F)+\beta Q_{\ell}^{(2)}(\lambda, F)
\end{aligned}
$$

for every $\beta>0$, where

$$
\begin{equation*}
A_{\ell}=\left\{A_{\ell, i}(\eta)\right\}_{i=1}^{d}:=\sum_{b=\{x, y\} \in(\Lambda(\ell))^{*}}\left(\eta_{y}-\eta_{x}\right)(y-x), \tag{3.28}
\end{equation*}
$$

denoting the box $\Lambda_{\ell, 0}$ with the center at 0 by $\Lambda(\ell)$, and

$$
\begin{equation*}
R(\rho ; F)=\widehat{c}(\rho ; F)-\widehat{c}(\rho) . \tag{3.29}
\end{equation*}
$$

The error $Q_{N, \ell}^{(1)} \equiv Q_{N, \ell}^{(1)}(\lambda, F)$ is estimated as

$$
\begin{equation*}
\left|Q_{N, \ell}^{(1)}\right| \leq C N^{-1} \ell^{(2 d+4)}\|\partial \lambda\|_{\infty}^{3}\left(1+\|F\|_{0, \infty}^{3}\right) . \tag{3.30}
\end{equation*}
$$

The other error $Q_{\ell}^{(2)} \equiv Q_{\ell}^{(2)}(\lambda, F)$ appears in the computation of the central limit theorem variance (see Section 4) and has a bound

$$
\begin{equation*}
\left|Q_{\ell}^{(2)}\right| \leq\|\partial \lambda\|_{\infty}^{2} Q_{\ell}(F) \tag{3.31}
\end{equation*}
$$

with $Q_{\ell}(F)$ bounded in Corollary 4.3 below.
Before giving a proof of Theorem 3.5, we prepare a key lemma by which one can reduce a non-equilibrium problem into a static problem under the canonical equilibrium measure, sometimes called the Kipnis-Varadhan estimate or the Itô-Tanaka trick. We introduce some notation. For $\Lambda \Subset \mathbb{Z}^{d}$ (i.e., finite subset) and $m \in[0,|\Lambda|] \cap \mathbb{Z}$,

$$
\begin{aligned}
& \mathcal{X}_{\Lambda}=\{0,1\}^{\Lambda}, \quad \mathcal{X}_{\Lambda, m}=\left\{\eta \in \mathcal{X}_{\Lambda} ; \sum_{x \in \Lambda} \eta_{x}=m\right\}, \\
& \nu_{\Lambda, m}=\text { uniform probability measure on } \mathcal{X}_{\Lambda, m},
\end{aligned}
$$

and $\langle\cdot\rangle_{\Lambda, m}$ denotes the expectation with respect to $\nu_{\Lambda, m}$. Then, we have a result similar to Lemmas 3.3 (the case $M(\rho)=0$ ) and 6.1 of [14], but the last term $\frac{C}{\beta}$ in their estimates is replaced by $\frac{C}{\beta} K$ due to the contribution from the Glauber part. We also show an estimate for the error term instead of taking the limit in $N$ as in [14].

Given a positive integer $\ell$, we write $G_{\zeta}=G_{\zeta}(\xi)$ for a function $G=G(\eta)$ when we consider $G$ as a function of $\xi=\left.\eta\right|_{\Lambda(\ell)}$ regarding $\zeta=\left.\eta\right|_{\Lambda(\ell)}$ c as a parameter. The following lemma will be used for the proof of Theorem 3.5 taking $n=d$ and for the proof of Lemma 3.7 below taking $n=1$.

Lemma 3.6. Let $n \in \mathbb{N}, J(t, v)=\left\{J_{i}(t, v)\right\}_{i=1}^{n} \in C^{\infty}\left([0, T] \times \mathbb{T}^{d}, \mathbb{R}^{n}\right), G(\eta)=\left\{G_{i}(\eta)\right\}_{i=1}^{n} \in$ $\mathcal{F}_{0}^{n}$ and $M(\rho)=\left\{M_{i j}(\rho)\right\}_{1 \leq i, j \leq n} \in C\left([0,1], \mathbb{R}^{n} \otimes \mathbb{R}^{n}\right)$. Let $1 \leq \ell \leq N / 2$ (in fact,
$\max _{|y|=1} r\left(c_{0, y}\right)<N-\ell$ is enough). Suppose that $\left\langle G_{\zeta}\right\rangle_{\Lambda(\ell), m}=0$ for every $\zeta$ and $m: 0 \leq m \leq \ell_{*}^{d}$. Then, there exists $C>0$ such that for every $\beta>0$

$$
\begin{aligned}
\int_{0}^{T} E^{f_{t}} & {\left[N^{1-d} \sum_{x \in \mathbb{T}_{N}^{d}} J(t, x / N) \cdot \tau_{x} G(\eta)-\beta N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} J(t, x / N) \cdot M\left(\bar{\eta}_{x}^{\ell}\right) J(t, x / N)\right] d t } \\
\leq & \beta T \sup _{|\theta| \leq\|J\|_{\infty}} \sup _{m, \zeta \in \mathcal{X}_{\Lambda(\ell)}}\left[d \ell_{*}^{d}\left\langle\theta \cdot G_{\zeta}\left(-L_{\Lambda(\ell), \zeta}\right)^{-1} \theta \cdot G_{\zeta}\right\rangle_{\Lambda(\ell), m}-\theta \cdot M\left(m / \ell_{*}^{d}\right) \theta\right] \\
& +\frac{C}{\beta} K+\beta^{2} Q_{N, \ell}^{(1)}(J, G),
\end{aligned}
$$

where $L_{\Lambda(\ell), \zeta}$ is the operator defined by

$$
\begin{equation*}
L_{\Lambda(\ell), \zeta} f(\xi)=\sum_{b \in(\Lambda(\ell))^{*}} c_{b}(\xi \cdot \zeta) \pi_{b} f(\xi), \tag{3.32}
\end{equation*}
$$

for $\xi \in \mathcal{X}_{\Lambda(\ell)}, \zeta \in \mathcal{X}_{\Lambda(\ell)}$, $f$ is a function on $\mathcal{X}_{\Lambda(\ell)}$ and $\xi \cdot \zeta$ denotes the configuration $\eta \in \mathcal{X}$ such that $\left.\eta\right|_{\Lambda(\ell)}=\xi$ and $\left.\eta\right|_{\Lambda(\ell)^{c}}=\zeta$. The error term $Q_{N, \ell}^{(1)} \equiv Q_{N, \ell}^{(1)}(J, G)$ has a bound

$$
\begin{equation*}
\left|Q_{N, \ell}^{(1)}\right| \leq C N^{-1} \ell^{(2 d+4)}\|G\|_{\infty}^{3}\|J\|_{\infty}^{3} . \tag{3.33}
\end{equation*}
$$

Proof. The proof is given by combining that of Lemma 6.1 of [14] and the calculation developed in that of Lemma 3.1 of [10] for Glauber-Kawasaki dynamics (see also Lemma 7.6 of [3] for Glauber-Zero range process).

Setting

$$
W_{N, t}(\eta)=N \sum_{x \in \mathbb{T}_{N}^{d}} J(t, x / N) \cdot \tau_{x} G-\beta \sum_{x \in \mathbb{T}_{N}^{d}} J(t, x / N) \cdot M\left(\bar{\eta}_{x}^{\ell}\right) J(t, x / N),
$$

by the entropy inequality (see (6.2) of [14]) noting that $H\left(P_{f_{0}} \mid P_{\nu^{N}}\right) \leq C N^{d}\left(P_{f_{0}}\right.$ denotes the distribution on the path space $D\left([0, T], \mathcal{X}_{N}\right)$ of $\eta^{N}(\cdot)$ with the initial distribution $f_{0} d \nu^{N}$ ) at the process level, we have

$$
\int_{0}^{T} E^{f_{t}}\left[N^{-d} W_{N, t}(\eta)\right] d t \leq \frac{1}{\beta} N^{-d} \log E_{\nu^{N}}\left[e^{\int_{0}^{T} \beta W_{N, t} d t}\right]+\frac{C}{\beta},
$$

for every $\beta>0$; recall $\nu^{N}=\nu_{1 / 2}^{N}$. Then, similar to (3.6) (with $\varepsilon=0, \varepsilon^{1-\Theta}=0$ ) of [10] shown for Glauber-Kawasaki dynamics, the right-hand side is bounded by

$$
\frac{1}{\beta} N^{-d} \int_{0}^{T} \Omega_{N, \beta}(t) d t+\frac{C}{\beta},
$$

where

$$
\Omega_{N, \beta}(t)=\sup _{\psi: \int \psi^{2} d \nu^{N}=1}\left\{E^{\nu^{N}}\left[\beta W_{N, t} \psi^{2}\right]-E^{\nu^{N}}\left[\psi\left(-\mathcal{L}_{N} \psi\right)\right]\right\} .
$$

Note that

$$
E^{\nu^{N}}\left[\psi\left(-\mathcal{L}_{N} \psi\right)\right]=N^{2} E^{\nu^{N}}\left[\psi\left(-L_{K} \psi\right)\right]+K E^{\nu^{N}}\left[\psi\left(-L_{G} \psi\right)\right] .
$$

For the Glauber part, it was shown in the proof of Lemma 3.1 of [10] that

$$
E^{\nu^{N}}\left[\psi\left(-L_{G} \psi\right)\right] \geq-C N^{d}
$$

This bound gives $\frac{C}{\beta} K$ in the final form of the estimate.
The contribution of the Kawasaki part is computed in [14] and the same bound holds in the present setting until the very end of the proof of Lemma 6.1 of [14]. In fact, (6.3) of [14] is the same as our $\Omega_{N, \beta}(t)$ without the contribution of the Glauber part. The only difference is that in (6.7) of [14], the limsup was taken as $N \rightarrow \infty$, but we have to derive the error estimate. The error is given by the second term in the estimate given in Theorem 6.1 of [14] (the Rayleigh-Schrödinger bound):

$$
Q_{N, \ell, \beta}(V):=\frac{N^{2} T}{\beta\left|(\Lambda(\ell))^{*}\right|} \times 4\|V\|_{\infty}^{3}\left(\sup _{f:\langle f\rangle_{\Lambda(\ell), m}=0} \frac{\left\langle f^{2}\right\rangle_{\Lambda(\ell), m}}{\left\langle-f L_{\Lambda(\ell), \zeta} f\right\rangle_{\Lambda(\ell), m}}\right)^{2}
$$

where $V=N^{-1} \beta\left|(\Lambda(\ell))^{*}\right| \theta \cdot G$; note that the front factor $\frac{N^{2} T}{\beta\left|(\Lambda(\ell))^{*}\right|}$ appears as in $\ell .4, \mathrm{p}$. 28 of [14] and because of the time integral. Since we have a spectral gap estimate for the Kawasaki generator:

$$
\begin{equation*}
\left\langle-f L_{\Lambda(\ell), \zeta} f\right\rangle_{\Lambda(\ell), m} \geq C_{0} \ell^{-2}\left\langle f^{2}\right\rangle_{\Lambda(\ell), m}, \tag{3.34}
\end{equation*}
$$

with a constant $C_{0}>0$ independent of $\zeta, m, \ell$ (see [22] or Appendix A of [14]), we have a bound for the error term:

$$
\begin{aligned}
\left|Q_{N, \ell, \beta}(V)\right| & \leq 4 T N^{-1} \beta^{2}\left|\Lambda(\ell)^{*}\right|^{2}\|\theta \cdot G\|_{\infty}^{3}\left(C_{0}^{-1} \ell^{2}\right)^{2} \\
& \leq C N^{-1} \beta^{2} \ell^{(2 d+4)}\|G\|_{\infty}^{3}\|J\|_{\infty}^{3}
\end{aligned}
$$

for $\theta:|\theta| \leq\|J\|_{\infty}$. This completes the proof of the lemma.
When $K=0$ (i.e. no Glauber part), the proof of Theorem 3.5 without error estimates was given in Sections 4-6 of [14]. Since only the Kawasaki part appears in the first term of the estimate in Lemma 3.6 above, the arguments in Sections 4 and 5 of 14 are applicable in our setting; see Section 4 below for more details and refined estimates.

To rewrite the function in the expectation in Theorem 3.5, we introduce the following three $\mathbb{R}^{d}$-valued functions $A_{\ell}, B_{\ell}$, and $H_{\ell}$ of $\eta$; in fact, $A_{\ell}$ is the same as in (3.28). We denote $\Psi_{i}=\eta_{e_{i}}-\eta_{0}$ and $W_{x, y}(\eta)=c_{x, y}(\eta)\left(\eta_{y}-\eta_{x}\right)$ for the microscopic current, where $e_{i} \in \mathbb{Z}^{d}$ stands for the unit vector in the $i$-th direction.

$$
\begin{align*}
A_{\ell}(\eta) \equiv A_{\ell}(\xi) & =\frac{1}{2} \sum_{x, y \in \Lambda(\ell):|x-y|=1}\left(\xi_{y}-\xi_{x}\right)(y-x)  \tag{3.35}\\
& =\sum_{i=1}^{d} \sum_{x: \tau_{x} e_{i}^{*} \in(\Lambda(\ell))^{*}} \tau_{x} \Psi_{i}(\xi) e_{i}, \\
B_{\ell}(\eta) \equiv B_{\ell, \zeta}(\xi) & =\frac{1}{2} \sum_{x, y \in \Lambda(\ell):|x-y|=1} W_{x, y}(\eta)(y-x) \tag{3.36}
\end{align*}
$$

$$
=-L_{\Lambda(\ell), \zeta}\left(\sum_{x \in \Lambda(\ell)} x \xi_{x}\right),
$$

and

$$
\begin{align*}
H_{\ell}(\eta) \equiv H_{\ell, \zeta, F}(\xi) & =\sum_{x \in \Lambda(\ell-n)} \tau_{x}\left(L^{N} F\right)(\xi \cdot \zeta)  \tag{3.37}\\
& =L_{\Lambda(\ell), \zeta}\left(\sum_{x \in \Lambda(\ell-n)} \tau_{x} F\right)(\xi),
\end{align*}
$$

for a given function $F=\left(F_{i}\right)_{i=1}^{d} \in \mathcal{F}_{0}^{d}$ which is $\mathcal{F}_{\Lambda(n-1)}$-measurable with $n=r(F)+1$.
Proof of Theorem 3.5. We apply Lemma 3.6 with $n=d, J(t, v)=\partial \lambda(t, v)$ and

$$
\begin{align*}
G(\eta) & =\ell_{*}^{-d}\left\{D\left(\bar{\eta}_{\ell}\right) A_{\ell}-B_{\ell}+H_{\ell}\right\}, \\
M(\rho) & =\frac{1}{2}\{\widehat{c}(\rho ; F)-\widehat{c}(\rho)\}\left(=\frac{1}{2} R(\rho ; F)\right) . \tag{3.38}
\end{align*}
$$

Then, we have $\|G\|_{\infty} \leq C\left(1+\|F\|_{0, \infty}\right)$. Indeed, the function $D=D(\rho)$ is bounded from (1.9), $\left\|A_{\ell}\right\|_{\infty} \leq C \ell_{*}^{d},\left\|B_{\ell}\right\|_{\infty} \leq C \ell_{*}^{d}$ since $W_{x, y}$ is bounded, and from

$$
H_{\ell}=\sum_{\{x, y\} \in \Lambda(\ell)^{*}} c_{x y}(\xi \cdot \zeta) \pi_{x y}\left(\sum_{z \in \Lambda(\ell-n)} \tau_{z} F\right),
$$

with $n=r(F)+1$, we have

$$
\left\|H_{\ell}\right\|_{\infty} \leq C \ell_{*}^{d} r(F)^{d}\|F\|_{\infty}=C \ell_{*}^{d}\|F\|_{0, \infty} .
$$

Thus, by (3.33), the error $Q_{N, \ell}^{(1)}(\lambda, F):=Q_{N, \ell}^{(1)}(J, G)$ with $J$ and $G$ determined as above has the estimate (3.30).

Then the proof is concluded by observing that
$Q_{\ell}^{(2)}\left(\|J\|_{\infty}, F\right):=\sup _{|\theta| \leq\|J\|_{\infty}} \sup _{m, \zeta \in \mathcal{X}_{\Lambda(\ell)^{c}}}\left\{\ell_{*}^{d}\left\langle\theta \cdot G_{\zeta},\left(-L_{\Lambda(\ell), \zeta}\right)^{-1} \theta \cdot G_{\zeta}\right\rangle_{\Lambda(\ell), m}-\theta \cdot M\left(m / \ell_{*}^{d}\right) \theta\right\}$
is bounded by $\|J\|_{\infty}^{2}\left|Q_{\ell}(F)\right|$ with $Q_{\ell}(F)$ given in Corollary 4.3. Taking $J=\partial \lambda$ and denoting $Q_{\ell}^{(2)}(\lambda, F):=Q_{\ell}^{(2)}\left(\|\partial\|_{\infty}, F\right)$, we obtain (3.31).

Next, we show the following lemma, in which we evaluate the error to rewrite the term appearing in Theorem 3.5 from $\Omega_{1}$ into another term of order $O(1)$.

Lemma 3.7. Set

$$
\begin{aligned}
Q_{N, \ell}^{(3)}(\lambda)=\int_{0}^{T} E^{f_{t}}\left[N^{1-d}\right. & \sum_{x \in \mathbb{T}_{N}^{d}}\left(D\left(\bar{\eta}_{x}^{\ell}\right) \partial \lambda(t, x / N), \ell_{*}^{-d} \tau_{x} A_{\ell}(\eta)\right) \\
& \left.+N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \sum_{i, j=1}^{d} \partial_{v_{i}} \partial_{v_{j}} \lambda(t, x / N) P_{i j}\left(\bar{\eta}_{x}^{\ell}\right)\right] d t,
\end{aligned}
$$

where $P(\rho) \equiv\left\{P_{i j}(\rho)\right\}_{1 \leq i, j \leq d}:=\int_{0}^{\rho} D\left(\rho^{\prime}\right) d \rho^{\prime}, \rho \in[0,1]$. Then, we have the following upper bound for $Q_{N, \ell}^{(3)} \equiv Q_{N, \ell}^{(3)}(\lambda)$ :

$$
Q_{N, \ell}^{(3)} \leq C\left(\ell^{-1}\left\|\partial^{2} \lambda\right\|_{\infty}+N^{-1}\left\|\partial^{3} \lambda\right\|_{\infty}\right)+C \beta \ell^{-1}\|\partial \lambda\|_{\infty}^{2}+\frac{C}{\beta} K+C \beta^{2} N^{-1} \ell^{2 d-2}\|\partial \lambda\|_{\infty}^{3}
$$

for every $\beta>0$.
Proof. We essentially follow the proof of Lemma 3.4 of [14, but make it more precise. Denote the first and second terms in the expectation $E^{f_{t}}[\cdots]$ by $I_{1}^{N}=I_{1}^{N}(t, \eta)$ and $I_{2}^{N}=I_{2}^{N}(t, \eta)$, respectively. Then, similar to the proof of Lemma 3.4 of [14] (but, with the - sign), we have the decomposition of $I_{1}^{N}$ :

$$
\begin{equation*}
I_{1}^{N}=J_{+}^{N}-J_{-}^{N}, \tag{3.39}
\end{equation*}
$$

where

$$
J_{ \pm}^{N}=N^{1-d} \ell_{*}^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \sum_{i, j=1}^{d} D_{i j}\left(\bar{\eta}_{x}^{\ell}\right) \partial_{v_{j}} \lambda(t, x / N) \tau_{x \pm \ell e_{i}} \widetilde{A}_{\ell, i}(\eta),
$$

and

$$
\widetilde{A}_{\ell, i}=\sum_{x \in \mathbb{Z}^{d}: x_{i}=0,\left|x_{j}\right| \leq \ell \text { for } j \neq i} \eta_{x} .
$$

However, $J_{-}^{N}$ can be rewritten as

$$
\begin{aligned}
J_{-}^{N} & =N^{1-d} \ell_{*}^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \sum_{i, j=1}^{d} D_{i j}\left(\bar{\eta}_{x-e_{i}}^{\ell}\right) \partial_{v_{j}} \lambda\left(t,\left(x-e_{i}\right) / N\right) \tau_{x-(\ell+1) e_{i}} \widetilde{A}_{\ell, i} \\
& =N^{1-d} \ell_{*}^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \sum_{i, j=1}^{d} D_{i j}\left(\bar{\eta}_{x-e_{i}}^{\ell}\right) \partial_{v_{j}} \lambda(t, x / N) \tau_{x-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}+Q_{1, \ell},
\end{aligned}
$$

with an error $Q_{1, \ell} \equiv Q_{1, \ell}(\lambda)$ bounded as

$$
\left|Q_{1, \ell}\right| \leq C_{1} \ell^{-1}\left\|\partial^{2} \lambda\right\|_{\infty},
$$

by noting $\partial_{v_{j}} \lambda\left(t,\left(x-e_{i}\right) / N\right)=\partial_{v_{j}} \lambda(t, x / N)+O\left(\left\|\partial^{2} \lambda\right\|_{\infty} / N\right)$ and $\tau_{x-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}=O\left(\ell^{d-1}\right)$.
Therefore, by (3.39), we obtain

$$
\begin{aligned}
I_{1}^{N}=N^{1-d} \ell_{*}^{-d} & \sum_{x \in \mathbb{T}_{N}^{d}} \sum_{i, j=1}^{d}\left\{D_{i j}\left(\bar{\eta}_{x}^{\ell}\right) \tau_{x+\ell e_{i}} \widetilde{A}_{\ell, i}\right. \\
& \left.-D_{i j}\left(\bar{\eta}_{x-e_{i}}^{\ell}\right) \tau_{x-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}\right\} \partial_{v_{j}} \lambda(t, x / N)-Q_{1, \ell} .
\end{aligned}
$$

On the other hand, since $\partial_{v_{i}} \partial_{v_{j}} \lambda(t, x / N)=N\left\{\partial_{v_{j}} \lambda\left(t,\left(x+e_{i}\right) / N\right)-\partial_{v_{j}} \lambda(t, x / N)\right\}+$ $O\left(\left\|\partial^{3} \lambda\right\|_{\infty} / N\right)$,

$$
I_{2}^{N}=-N^{1-d} \sum_{x \in \mathbb{T}_{N}^{d}} \sum_{i, j=1}^{d}\left\{P_{i j}\left(\bar{\eta}_{x}^{\ell}\right)-P_{i j}\left(\bar{\eta}_{x-e_{i}}^{\ell}\right)\right\} \partial_{v_{j}} \lambda(t, x / N)+Q_{2, N},
$$

with an error $Q_{2, N} \equiv Q_{2, N}(\lambda)$ bounded as

$$
\left|Q_{2, N}\right| \leq C_{2} N^{-1}\left\|\partial^{3} \lambda\right\|_{\infty}
$$

Note that $P_{i j}(\rho)$ is bounded.
From these two equalities for $I_{1}^{N}$ and $I_{2}^{N}, Q_{N, \ell}^{(3)}(\lambda)$ in the statement of the lemma is rewritten as

$$
\begin{equation*}
\int_{0}^{T} E^{f_{t}}\left[N^{1-d} \sum_{x \in \mathbb{T}_{N}^{d}} \sum_{i, j=1}^{d} \partial_{v_{j}} \lambda(t, x / N) Q_{i j ; \ell}(x, \eta)-Q_{1, \ell}+Q_{2, N}\right] d t, \tag{3.40}
\end{equation*}
$$

where

$$
\begin{aligned}
Q_{i j ; \ell}(x, \eta)= & -P_{i j}\left(\bar{\eta}_{x}^{\ell}\right)+P_{i j}\left(\bar{\eta}_{x-e_{i}}^{\ell}\right) \\
& +\ell_{*}^{-d}\left\{D_{i j}\left(\bar{\eta}_{x}^{\ell}\right) \tau_{x+\ell e_{i}} \widetilde{A}, i-D_{i j}\left(\bar{\eta}_{x-e_{i}}^{\ell}\right) \tau_{x-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}\right\} .
\end{aligned}
$$

Now, we apply Lemma 3.6 to estimate (3.40) (except $Q_{1, \ell}$ and $Q_{2, N}$ ) for each fixed $i$ and $j$ from the above; namely, take $n=1, J(t, v)=\partial_{v_{j}} \lambda(t, v), G(\eta) \equiv G_{i j}(\eta)=Q_{i j ; \ell}(0, \eta)$, $M(\rho)=0$ and apply Lemma 3.6 with $\ell+1$ instead of $\ell$ by noting that $\langle G\rangle_{\Lambda(\ell+1), m}=0$ for any $0 \leq m \leq(\ell+1)_{*}^{d} \equiv|\Lambda(\ell+1)|$. Then, noting $\|J\|_{\infty} \leq\|\partial \lambda\|_{\infty}$, we see that (3.40) (except for $Q_{1, \ell}$ and $Q_{2, N}$ ) is bounded by the sum in $i, j$ (note $G=G_{i j}$ ) of

$$
\begin{align*}
& \beta T\|\partial \lambda\|_{\infty}^{2} d(\ell+1)_{*}^{d} \sup _{m, \zeta \in \mathcal{X}_{\Lambda(\ell+1)^{c}}}\left\langle G,\left(-L_{\Lambda(\ell+1), \zeta}\right)^{-1} G\right\rangle_{\Lambda(\ell+1), m}  \tag{3.41}\\
& \quad+\frac{C}{\beta} K+\beta^{2} Q_{N, \ell+1}^{(1)}(\partial \lambda, G) .
\end{align*}
$$

Therefore, recalling the spectral gap of $L_{\Lambda(\ell), \zeta}$ given in (3.34), that is, $\left(-L_{\Lambda(\ell+1), \zeta}\right)^{-1} \leq$ $C_{0}^{-1}(\ell+1)^{2}$, the first term of (3.41) is bounded by

$$
\begin{equation*}
C \beta\|\partial \lambda\|_{\infty}^{2} \ell^{d+2}\left\langle G^{2}\right\rangle_{\Lambda(\ell+1), m} . \tag{3.42}
\end{equation*}
$$

However, by applying Taylor's formula to $P_{i j}$, we have

$$
P_{i j}\left(\bar{\eta}_{0}^{\ell}\right)-P_{i j}\left(\bar{\eta}_{-e_{i}}^{\ell}\right)=D_{i j}\left(\bar{\eta}_{0}^{\ell}\right) \varphi_{i, \ell}(\eta)+\frac{1}{2} D_{i j}^{\prime}\left(\rho^{*}\right) \varphi_{i, \ell}(\eta)^{2}
$$

with some $\rho^{*} \in[0,1]$, where

$$
\begin{align*}
\varphi_{i, \ell}(\eta) & =\bar{\eta}_{0}^{\ell}-\bar{\eta}_{-e_{i}}^{\ell}  \tag{3.43}\\
& =\ell_{*}^{-d}\left\{\tau_{\ell e_{i}} \widetilde{A}_{\ell, i}-\tau_{-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}\right\} .
\end{align*}
$$

Therefore, after cancelling common terms $\ell_{*}^{-d} D_{i j}\left(\bar{\eta}_{0}^{\ell}\right) \tau_{\ell \ell_{i}} \widetilde{A}_{\ell, i}$, we have

$$
\begin{align*}
G(\eta) & =\ell_{*}^{-d}\left\{D_{i j}\left(\bar{\eta}_{0}^{\ell}\right)-D_{i j}\left(\bar{\eta}_{-e_{i}}^{\ell}\right)\right\} \tau_{-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}-\frac{1}{2} D_{i j}^{\prime}\left(\rho^{*}\right) \varphi_{i, \ell}(\eta)^{2}  \tag{3.44}\\
& =\ell_{*}^{-d} D_{i j}^{\prime}\left(\rho^{* *}\right) \varphi_{i, \ell}(\eta) \tau_{-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}-\frac{1}{2} D_{i j}^{\prime}\left(\rho^{*}\right) \varphi_{i, \ell}(\eta)^{2}
\end{align*}
$$

$$
\begin{aligned}
&=\ell_{*}^{-d} D_{i j}^{\prime}\left(\rho^{* *}\right) \varphi_{i, \ell}(\eta)\left(\tau_{-(\ell+1) e_{i}} \widetilde{A}_{\ell, i}-\bar{A}_{\ell, m}\right) \\
&+\ell_{*}^{-d} D_{i j}^{\prime}\left(\rho^{* *}\right) \varphi_{i, \ell}(\eta) \bar{A}_{\ell, m}-\frac{1}{2} D_{i j}^{\prime}\left(\rho^{*}\right) \varphi_{i, \ell}(\eta)^{2}
\end{aligned}
$$

with some $\rho^{* *} \in[0,1]$, where $\bar{A}_{\ell, m}:=\left\langle\widetilde{A}_{\ell, i}\right\rangle_{\Lambda(\ell+1), m} \in\left[0, \ell_{*}^{d-1}\right]$. We have used Taylor's formula again. Since $D_{i j}^{\prime}(\rho)$ is bounded due to (1.8) and

$$
\begin{gather*}
\left\langle\left\{\tau_{-(\ell+1) e_{i}} \tilde{A}_{\ell, i}-\bar{A}_{\ell, m}\right\}^{4}\right\rangle_{\Lambda(\ell+1), m} \leq C_{3} \ell^{2(d-1)},  \tag{3.45}\\
\left\langle\varphi_{i, \ell}(\eta)^{4}\right\rangle_{\Lambda(\ell+1), m} \leq C_{3} \ell^{-2(d+1)}, \tag{3.46}
\end{gather*}
$$

we obtain that (3.42) is bonded by

$$
C \beta\|\partial \lambda\|_{\infty}^{2} \ell^{d+2}\left\{\ell^{-2 d} \sqrt{\ell^{-2(d+1)} \ell^{2(d-1)}}+\ell^{-d-3}+\ell^{-2(d+1)}\right\} \leq 3 C \beta\|\partial \lambda\|_{\infty}^{2} \ell^{-1} .
$$

Here, (3.45) (i.e. in CLT scaling) follows by using Lemma A. 2 in Appendix of 14 taking $n=(\ell+1)_{*}^{d}$ (indeed, the sum of the terms of the form $\left\langle\left(\eta_{1}-m / n\right)^{2}\left(\eta_{2}-m / n\right)^{2}\right\rangle(\leq 1)$ gives the leading order), (3.46) follows from (3.43) and (3.45), and the expectation under $\nu_{\Lambda(\ell+1), m}$ of the square of the middle term on the right-hand side of (3.44) is $O\left(\ell^{-d-3}\right)$ from (3.46).

For $Q_{N, \ell+1}^{(1)} \equiv Q_{N, \ell+1}^{(1)}(\partial \lambda, G)$ in (3.41), since $\|G\|_{\infty} \leq C_{4} \ell^{-2}$ from (3.44), $0 \leq \widetilde{A}_{\ell, i} \leq$ $\ell_{*}^{d-1}$ and $\left|\varphi_{i, \ell}(\eta)\right| \leq \ell_{*}^{-1}$, we have by (3.33) in Lemma 3.6

$$
\left|Q_{N, \ell+1}^{(1)}\right| \leq C N^{-1} \ell^{(2 d+4)} \ell^{-6}\|\partial \lambda\|_{\infty}^{3}=C N^{-1} \ell^{(2 d-2)}\|\partial \lambda\|_{\infty}^{3}
$$

Summarizing these, we obtain the desired upper bound for $Q_{N, \ell}^{(3)}(\lambda)$.

### 3.4 Summary of estimate for $h_{N}(t)$ obtained in above three subsections

Lemma 3.1 (calculation for $\partial_{t} h_{N}(t)$ ), Theorem 3.3 (refined one-block estimate) and Theorem 3.5 (Boltzmann-Gibbs principle for gradient replacement, postponing the estimates for the CLT variances to Section (4) are summarized in the following lemma. The constant $C=C_{T}>0$ may depend on $T$.

Lemma 3.8. Assume $\lambda \in C^{1,3}\left([0, T] \times \mathbb{T}^{d}\right), F \in \mathcal{F}_{0}^{d}$ and the conditions (3.4) and (3.24). Then, setting $\rho(t, v)=\bar{\rho}(\lambda(t, v))$, we have

$$
\begin{aligned}
h_{N}(t) & \leq h_{N}(0)+\int_{0}^{t} E^{f_{t}}[W] d t+Q_{N, \ell, \beta, K}^{\Omega_{1}}(\lambda, F) \\
& +C(\beta+1)\|\partial \lambda\|_{\infty}^{2} \sup _{\rho}\|R(\rho ; F)\|+Q_{N}^{E n}(\lambda, F)+Q_{N, \ell}^{\Omega_{2}}(\lambda, F),
\end{aligned}
$$

for every $\beta>0$ and $1 \leq \ell \leq N / 2$, where $\|R\|$ denotes the operator norm of matrix $R$ (recall (3.29) for $R$ ), $Q_{N}^{E n}(\lambda, F)$ is in Lemma 3.1 and

$$
\begin{equation*}
Q_{N, \ell, \beta, K}^{\Omega_{1}}(\lambda, F):=\frac{C}{\beta} K+\beta^{2} Q_{N, \ell}^{(1)}(\lambda, F)+\beta Q_{\ell}^{(2)}(\lambda, F)+Q_{N, \ell}^{(3)}(\lambda), \tag{3.47}
\end{equation*}
$$

see Theorem [3.5 for $Q_{N, \ell}^{(1)}, Q_{\ell}^{(2)}$ and Lemma 3.7 for $Q_{N, \ell}^{(3)}$. The function $W$ is defined by

$$
\begin{aligned}
W(\eta)= & -N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \dot{\lambda}(t, x / N)\left\{\bar{\eta}_{x}^{\ell}-\rho(t, x / N)\right\} \\
& +N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \operatorname{Tr}\left(\partial^{2} \lambda(t, x / N)\left\{P\left(\bar{\eta}_{x}^{\ell}\right)-P(\rho(t, x / N))\right\}\right) \\
& +\frac{N^{-d}}{2} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, x / N),\left\{\widehat{c}\left(\bar{\eta}_{x}^{\ell}\right)-\widehat{c}(\rho(t, x / N))\right\} \partial \lambda(t, x / N)\right) \\
& +N^{-d} K \sum_{x \in \mathbb{T}_{N}^{d}} \sigma_{G}\left(\bar{\eta}_{x}^{\ell} ; t, x / N\right),
\end{aligned}
$$

where

$$
\begin{equation*}
\sigma_{G}(u ; t, v)=\left(\frac{\left\langle c^{+}\right\rangle_{u}}{\rho(t, v)}-\frac{\left\langle c^{-}\right\rangle_{u}}{1-\rho(t, v)}\right)\{u-\rho(t, v)\} . \tag{3.48}
\end{equation*}
$$

The error $Q_{N, \ell}^{\Omega_{2}}(\lambda, F)$ is estimated as

$$
\begin{align*}
\left|Q_{N, \ell}^{\Omega_{2}}(\lambda, F)\right| \leq & C\left(N^{-1} K^{1 / 2} \ell^{(d+2) / 2}+\ell^{-d}\left(1+r(F)^{d}\right)\right)  \tag{3.49}\\
& \times\left(\|\dot{\lambda}\|_{\infty}+\|\partial \lambda\|_{\infty}^{2}\left(1+\|\mid F\|_{0, \infty}\right)^{2}+\left\|\partial^{2} \lambda\right\|_{\infty}\left(1+\|F\|_{1, \infty}\right)+K\right) \\
+ & C N^{-1}\left(\left\|\partial^{3} \lambda\right\|_{\infty}+\left\|\partial^{2} \lambda\right\|_{\infty}\|\partial \lambda\|_{\infty}+\|\partial \lambda\|_{\infty}^{2}\|\partial \lambda\|_{\infty}\right) .
\end{align*}
$$

In the above estimate, for each $\lambda_{*}>0$, the constant $C=C_{\lambda_{*}}$ can be taken uniformly for $\lambda=\lambda(t, v)$ such that $\|\lambda\|_{\infty} \leq \lambda_{*}$.

When we apply this lemma later in Lemma 3.13, we take $\lambda(t, v)=\bar{\lambda}\left(\rho_{K}(t, v)\right)$ with a solution $\rho_{K}$ of (1.11). Under the condition (1.12) for the initial value $\rho_{0}$, by Lemma 7.1 (the comparison theorem for $\rho_{K}$ ) and recalling (1.15), $\lambda_{*}$ can be taken to be uniform in $K$.

Proof. The proof is similar to Lemma 3.2 of [14], but compared to it, we have the Glauber part and also require to derive an appropriate error estimate. For $\Omega_{1}$, we apply Theorem 3.5 (with an error $\frac{C}{\beta} K+\beta^{2} Q_{N, \ell}^{(1)}+\beta Q_{\ell}^{(2)}$ ) and Lemma 3.7 (with an error $Q_{N, \ell}^{(3)}$ ), and obtain a similar replacement of $\int_{0}^{t} E^{f_{t}}\left[\Omega_{1}\right] d t$ by the following integral shown on p. 15 of [14]:

$$
\begin{aligned}
& \int_{0}^{t}\left\{E^{f_{t}}\left[N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \operatorname{Tr}\left(\partial^{2} \lambda(t, x / N) P\left(\bar{\eta}_{x}^{\ell}\right)\right)\right]\right. \\
& \left.\quad+E^{f_{t}}\left[\frac{\beta N^{-d}}{2} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(t, x / N), R\left(\bar{\eta}_{x}^{\ell} ; F\right) \partial \lambda(t, x / N)\right)\right]\right\} d t
\end{aligned}
$$

with an error replacing $\frac{C t}{\beta}+o(1)$ by $Q_{N, \ell, \beta, K}^{\Omega_{1}}(\lambda, F)$ defined in (3.47). The second term is bounded by $C \beta\|\partial \lambda\|_{\infty}^{2} \sup _{\rho}\|R(\rho ; F)\|$ on the right-hand side of the desired estimate for $h_{N}(t)$.

For $\Omega_{2}$, we apply (3.25) in Theorem 3.3 (refined one-block estimate) to replace $\int_{0}^{t} E^{f_{t}}\left[\Omega_{2}\right] d t$ by

$$
\begin{align*}
\int_{0}^{t} E^{f_{t}}\left[N^{-d}\right. & \sum_{x \in \mathbb{T}_{N}^{d}}\left\{-\dot{\lambda}(t, x / N) \bar{\eta}_{x}^{\ell}\right.  \tag{3.50}\\
& \left.\left.+\frac{1}{2}\left(\partial \lambda(t, x / N), \widehat{c}\left(\bar{\eta}_{x}^{\ell} ; F\right) \partial \lambda(t, x / N)\right)+K \sigma_{G}\left(\bar{\eta}_{x}^{\ell} ; t, x / N\right)\right\}\right] d t
\end{align*}
$$

Note that the ensemble averages of the third and fourth terms of $\Omega_{2}$ vanish: $\left\langle c_{x y}\left(\eta_{x}-\right.\right.$ $\left.\left.\eta_{y}\right)\right\rangle_{\rho}=0,\left\langle c_{x y} \pi_{x y} G\right\rangle_{\rho}=0$ for all $G=G(\eta) \in \mathcal{F}_{0}$. The error for this replacement is estimated by

$$
\begin{aligned}
& C\left(N^{-1} K^{1 / 2} \ell^{(d+2) / 2}+\ell^{-d}\left(1+r(F)^{d}\right)\right) \\
& \quad \times\left(\|\dot{\lambda}\|_{\infty}+\|\partial \lambda\|_{\infty}^{2}\left(1+\|F\|_{0, \infty}\right)^{2}+\left\|\partial^{2} \lambda\right\|_{\infty}\left(1+\|F\|_{1, \infty}\right)+K\right)
\end{aligned}
$$

by applying Theorem 3.3 taking $M=\|\dot{\lambda}\|_{\infty}$ for the first term of $\Omega_{2}, M\|h\|_{\infty} \leq C\|\partial \lambda\|_{\infty}^{2}(1+$ $\left.\|F F\|_{0, \infty}\right)^{2}$ for the second term, $M\|h\|_{\infty} \leq C\left\|\partial^{2} \lambda\right\|_{\infty}$ for the third term, $M\|h\|_{\infty} \leq$ $C\left\|\partial^{2} \lambda\right\|_{\infty}\|F F\|_{1, \infty}$ for the fourth term and $M\|h\|_{\infty} \leq C K$ for the fifth term noting that $\rho(t, v)$ is uniformly away from 0 and $1: e^{-\lambda_{*}} /\left(e^{-\lambda_{*}}+1\right) \leq \rho(t, v) \leq e^{\lambda_{*}} /\left(e^{\lambda_{*}}+1\right)$ for $\lambda$ such that $\|\lambda\|_{\infty} \leq \lambda_{*}$. This gives the first term in the error estimate of $\left|Q_{N, \ell}^{\Omega_{2}}(\lambda, F)\right|$.

Note that $\widehat{c}\left(\bar{\eta}_{x}^{\ell} ; F\right)$ in (3.50) can be replaced by $\widehat{c}\left(\bar{\eta}_{x}^{\ell}\right)$ with an error $C\|\partial \lambda\|_{\infty}^{2} \sup _{\rho}\|R(\rho ; F)\|$.
The reason that we have the second term in the error estimate of $\left|Q_{N, \ell}^{\Omega_{2}}(\lambda, F)\right|$ in (3.49) is as follows. Recalling that $\rho(t, v)=\bar{\rho}(\lambda(t, v))$, we have the identity

$$
\begin{equation*}
-\int_{\mathbb{T}^{d}} \operatorname{Tr}\left(\partial^{2} \lambda(t, v) P(\rho(t, v))\right) d v=\frac{1}{2} \int_{\mathbb{T}^{d}}(\partial \lambda(t, v), \widehat{c}(\rho(t, v)) \partial \lambda(t, v)) d v, \tag{3.51}
\end{equation*}
$$

This is shown by integration by parts and noting

$$
\begin{equation*}
\frac{\partial \bar{\rho}}{\partial \lambda}=\chi(\rho) . \tag{3.52}
\end{equation*}
$$

The terms with $\rho(t, x / N)$ in the second and third terms of $W$ cancels by this identity with an error bounded by

$$
C N^{-1}\left(\left\|\partial^{3} \lambda\right\|_{\infty}+\left\|\partial^{2} \lambda\right\|_{\infty}\|\partial \rho\|_{\infty}+\left\|\partial^{2} \lambda\right\|_{\infty}\|\partial \lambda\|_{\infty}+\|\partial \lambda\|_{\infty}^{2}\|\partial \rho\|_{\infty}\right),
$$

which appears when we discretize the above two integrals in (3.51); note that $P, \widehat{c}$ are bounded and $P, \widehat{c} \in C^{\infty}((0,1))$. Note that $\|\partial \rho\|_{\infty}$ is uniformly bounded by $\|\partial \lambda\|_{\infty}$ for $\lambda$ such that $\|\lambda\|_{\infty} \leq \lambda_{*}$.

### 3.5 Entropy inequality and large deviation error estimate

In Lemma 3.8, $E^{f_{t}}[W]$ is an expectation under $P^{f_{t}}=f_{t} d \nu^{N}$. We apply the entropy inequality to reduce it to the expectation under $P^{\psi_{t}}=\psi_{t} d \nu^{N}$ :

$$
\begin{equation*}
E^{f_{t}}[W] \leq \frac{K}{\delta N^{d}} \log E^{\psi_{t}}\left[e^{\delta N^{d} K^{-1} W}\right]+\frac{K}{\delta} h_{N}(t), \tag{3.53}
\end{equation*}
$$

for every $\delta>0$ (different from $\delta>0$ in $\bar{K}_{\delta}(N)$ ). We study the asymptotic behavior of the first term on the right-hand side via a large deviation type upper bound with an appropriate error estimate under $\psi_{t} d \nu^{N}$; see Theorem 3.9 below.

For $\lambda(\cdot) \in C^{1}\left(\mathbb{T}^{d}\right)$ and $F=F(\eta) \in \mathcal{F}_{0}^{d}$, dropping the $t$-dependence in (2.1), the local equilibrium state $\psi_{\lambda(\cdot), F}^{N}(\eta) d \nu^{N}$ of second order approximation is a probability measure on $\mathcal{X}_{N}$ defined by

$$
\begin{equation*}
\psi_{\lambda(\cdot), F}^{N}(\eta)=Z^{-1} \exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(x / N) \eta_{x}+\frac{1}{N} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(x / N), \tau_{x} F(\eta)\right)\right\}, \tag{3.54}
\end{equation*}
$$

for $\eta \in \mathcal{X}_{N}$, where $Z=Z_{\lambda(\cdot), F, N}$ is the normalization constant with respect to $\nu^{N}$. Then we have the following large deviation type upper bound for $\psi_{\lambda(\cdot), F}^{N} d \nu^{N}$. A similar result is shown in Lemmas 5 and 7 of [30] in the case of $F \equiv 0$ and Theorem 3.3 of [14]. But here, we give its error estimate.

The Bernoulli measure on $\mathcal{X}$ associated with the chemical potential $\lambda \in \mathbb{R}$ is denoted by $\nu_{\lambda}$, that is, $\nu_{\lambda}=\bar{\nu}_{\lambda}^{\otimes \mathbb{Z}^{d}}$, where $\bar{\nu}_{\lambda}$ is a probability measure on $\{0,1\}$ defined by $\bar{\nu}_{\lambda}(\eta):=e^{\lambda \eta} /\left(e^{\lambda}+1\right), \eta=0,1$. We abuse the notation $\nu_{\lambda}$ and $\nu_{\rho}$ which have different parametrizations but are clearly distinguishable. Indeed, $\nu_{\lambda}=\nu_{\bar{\rho}(\lambda)}$, i.e. $\nu_{\rho}$ with $\rho=\bar{\rho}(\lambda)$ defined by (1.14).

The rate function for the large deviation principle for the Bernoulli measure $\nu_{\lambda}$ is denoted by $I(u ; \lambda)$, namely, for $u \in[0,1]$,

$$
\begin{align*}
& I(u ; \lambda)=-\lambda u-q(u)+p(\lambda) \\
& p(\lambda)=\log \left(e^{\lambda}+1\right), \quad q(u)=-\{u \log u+(1-u) \log (1-u)\} \tag{3.55}
\end{align*}
$$

see Section 3.8 for more details.
When we apply the following theorem later, we take $K=K(N)$, but in this theorem, we consider $K$ as a parameter in the function $G(v, \rho)$, such that $\frac{1}{K} \in(0,1]$, and derive an estimate which is uniform in $\frac{1}{R}$.
Theorem 3.9. For every $G_{1}(v, \rho), G_{2}(v, \rho) \in C^{1}\left(\mathbb{T}^{d} \times[0,1]\right)$, we have

$$
\begin{aligned}
& N^{-d} \log E^{\psi_{\lambda(\cdot), F}^{N}}[\exp \widetilde{G}(\eta)] \\
\leq & \sup _{\rho(v) \in C\left(\mathbb{T}^{d} ;[0,1]\right)} \int_{\mathbb{T}^{d}}\{G(v, \rho(v))-I(\rho(v) ; \lambda(v))\} d v+Q_{N, \ell}^{L D}(\lambda, F ; G),
\end{aligned}
$$

where $G(v, \rho)=G_{1}(v, \rho)+\frac{1}{K} G_{2}(v, \rho)$ and

$$
\begin{equation*}
\widetilde{G}(\eta) \equiv \widetilde{G}_{N, \ell}(\eta)=\sum_{x \in \mathbb{T}_{N}^{d}} G\left(x / N, \bar{\eta}_{x}^{\ell}\right) . \tag{3.56}
\end{equation*}
$$

The error term $Q_{N, \ell}^{L D}(\lambda, F ; G)$ has an estimate which is uniform in $\frac{1}{K} \in(0,1]$ :

$$
\begin{aligned}
\left|Q_{N, \ell}^{L D}(\lambda, F ; G)\right| \leq & C N^{-1}\|\partial \lambda\|_{\infty}\|F\|_{\infty}+C N^{-1} \ell\left(\|\partial \lambda\|_{\infty}+\left\|\partial G_{1}\right\|_{\infty}+\left\|\partial G_{2}\right\|_{\infty}\right) \\
& +C \ell^{-d}\left(\log \ell+\|\lambda\|_{\infty}+\left\|\partial_{\rho} G_{1}\right\|_{\infty}+\left\|\partial_{\rho} G_{2}\right\|_{\infty}\right)
\end{aligned}
$$

where $\partial G_{i}=\partial_{v} G_{i}$ for $i=1,2$.

This theorem will be shown in Section 3.8. We will apply this theorem for the first term on the right-hand side of (3.53), which determines $G_{1}$ and $G_{2}$ by

$$
\begin{equation*}
\delta N^{d} K^{-1} W(\eta)=\sum_{x \in \mathbb{T}_{N}^{d}}\left\{G_{1}\left(x / N, \bar{\eta}_{x}^{\ell}\right)+K^{-1} G_{2}\left(x / N, \bar{\eta}_{x}^{\ell}\right)\right\} \tag{3.57}
\end{equation*}
$$

see Theorem 3.11 below. The definition of $\widetilde{G}$ was slightly different from (3.56) in Theorem 3.3 of [14], but (3.56) is more convenient for our application.

The following corollary was used in Section 2; see (2.6). The contribution of $F_{N}$ is negligible because of the property $\left\|F_{N}\right\|_{\infty} \leq C N^{1-\epsilon}$ for some $C, \epsilon>0$.

Corollary 3.10. Choose $\lambda=\lambda_{N}$ and $F=F_{N}$ as in Section 5.2 below, namely, $\lambda=\lambda_{K(N)}$ with $K(N) \leq \bar{\delta} \log N$ for some $\bar{\delta}>0$ and $\lambda_{K}$ satisfying $\left\|\partial \lambda_{K}\right\|_{3, \infty} \leq C K^{\gamma}$ for some $\gamma>0$, $F=\Phi_{n(N)}$ with $\Phi_{n}$ and $n(N)=N^{a_{1}}$ satisfying (5.10) and (5.11). Then, we have

$$
\varlimsup_{N \rightarrow \infty} N^{-d} \log P_{\lambda(\cdot), F}^{\psi^{N}}\left(\mathcal{A}_{N, \phi, \varepsilon}\right)<0, \quad \varepsilon>0, \phi \in C^{\infty}\left(\mathbb{T}^{d}\right)
$$

where $\mathcal{A}_{N, \phi, \varepsilon}$ is the subset of $\mathcal{X}_{N}$ defined by (2.5) with $\rho^{N}(t)$ and $\rho_{K}(t, v)$ replaced by $\rho^{N}$ defined by (1.4) with $\eta_{x}$ instead of $\eta_{x}^{N}(t)$ and $\bar{\rho}(\lambda(v))$, respectively.

Proof. We follow the proof of Corollary B. 1 of [14]. Consider

$$
g(\eta) \equiv g_{\ell}(\eta)=N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \phi(x / N)\left\{\bar{\eta}_{x}^{\ell}-\bar{\rho}(\lambda(x / N))\right\}
$$

Then, from $\phi \in C^{\infty}\left(\mathbb{T}^{d}\right)$ and the conditions for $\lambda$ and $\ell=N^{a_{2}}=N^{1 /(2 d+5)}, \mathcal{A}_{N, \phi, \varepsilon} \subset$ $\{|g(\eta)|>\varepsilon / 2\}$ for large enough $N$. Furthermore, taking $G(v, \rho)=\phi(v)\{\rho-\bar{\rho}(\lambda(v))\}-\varepsilon / 2$, by (3.56)

$$
\widetilde{G}(\eta) \equiv \widetilde{G}_{N, \ell}(\eta)=\sum_{x \in \mathbb{T}_{N}^{d}}\left[\phi(x / N)\left\{\bar{\eta}_{x}^{\ell}-\bar{\rho}(\lambda(x / N))\right\}-\varepsilon / 2\right]=N^{d}\{g(\eta)-\varepsilon / 2\}
$$

Therefore, by Theorem 3.9, for any $\delta>0$

$$
\begin{aligned}
& N^{-d} \log P^{\psi_{\lambda(\cdot), F}^{N}}(g(\eta)>\varepsilon / 2) \leq N^{-d} \log E^{\psi_{\lambda(\cdot), F}^{N}}\left[e^{\delta \widetilde{G}_{N, \ell}}\right] \\
& \quad \leq \sup _{\rho(v) \in C\left(\mathbb{T}^{d} ;[0,1]\right)} \int_{\mathbb{T}^{d}}\{\delta G(v, \rho(v))-I(\rho(v) ; \lambda(v))\} d v+Q_{N, \ell}^{L D}(\lambda, F ; \delta G) .
\end{aligned}
$$

However, for the large deviation rate function $I(\rho ; \lambda)$, we have

$$
\begin{equation*}
I(\rho ; \lambda(v)) \geq C(\rho-\bar{\rho}(\lambda(v)))^{2}, \quad \rho \in[0,1] \tag{3.58}
\end{equation*}
$$

for some $C>0$, since $\frac{\partial^{2} I}{\partial u^{2}}(u ; \lambda)=\frac{1}{\chi(u)}>0$ and $I(u ; \lambda)=0$ if and only if $u=\bar{\rho}(\lambda)$. From this, we see that there exists $\delta>0$ small enough such that

$$
\delta G(v, \rho)-I(\rho ; \lambda(v)) \leq-\varepsilon \delta / 4
$$

for all $\rho \in[0,1]$.

For the error term, noting $\phi \in C^{\infty}\left(\mathbb{T}^{d}\right)$, we have

$$
\left|Q_{N, \ell}^{L D}(\lambda, F ; \delta G)\right| \leq C N^{-1}\|\partial \lambda\|_{\infty}\|F\|_{\infty}+C N^{-1} \ell\left(1+\|\partial \lambda\|_{\infty}\right)+C \ell^{-d}\left(\log \ell+\|\lambda\|_{\infty}\right),
$$

which tends to 0 as $N \rightarrow \infty$ under the choice of $\lambda=\lambda_{N}, F=F_{N}$ and $\ell=\ell(N)$ stated above. This concludes

$$
\varlimsup_{N \rightarrow \infty} N^{-d} \log P^{\psi_{\lambda(\cdot), F}^{N}}(g(\eta)>\varepsilon / 2)<0 .
$$

A similar result can be shown for the event $\{g(\eta)<-\varepsilon / 2\}$. This completes the proof of the corollary.

### 3.6 Further estimate for $h_{N}(t)$

The next theorem is immediate by combing Lemma [3.8, (3.53) and Theorem [3.9, A corresponding result was given for $h(t)=\overline{\lim }_{N \rightarrow \infty} h_{N}(t)$ in Theorem 2.1 of [14] (the error estimate of $o(1)$ was sufficient in [14]). But, in the present setting, for the reason already noted, we need a bound for $h_{N}(t)$ with an appropriate error estimate.

To state the theorem, let us define $g(t)$ as follows:

$$
\begin{aligned}
& g(t) \equiv g_{\delta, K}(t)=\sup _{u(v) \in C\left(\mathbb{T}^{d} ;[0,1]\right)} \int_{\mathbb{T}^{d}}\left\{\frac{\delta}{K} \cdot \sigma(u(v) ; t, v)-I(u(v) ; \lambda(t, v))\right\} d v, \\
& \sigma(u ; t, v) \equiv \sigma_{K}(u ; t, v)=-\dot{\lambda}(t, v)\{u-\rho(t, v)\}+\operatorname{Tr}\left(\partial^{2} \lambda(t, v)\{P(u)-P(\rho(t, v))\}\right) \\
& \\
& \quad+\frac{1}{2}(\partial \lambda(t, v),\{\widehat{c}(u)-\widehat{c}(\rho(t, v))\} \partial \lambda(t, v))+K \sigma_{G}(u ; t, v) .
\end{aligned}
$$

Recall $\rho(t, v)=\bar{\rho}(\lambda(t, v))$, Lemma 3.7 for $P(\rho)$ and (3.48) for $\sigma_{G}(u ; t, v)$.
In view of (3.57) and $W$ given in Lemma 3.8, we take

$$
\begin{align*}
G_{1}(v, \rho)= & \delta \cdot \sigma_{G}(\rho ; t, v), \\
G_{2}(v, \rho)= & \delta\left[-\dot{\lambda}(t, v)\{\rho-\rho(t, v)\}+\operatorname{Tr}\left(\partial^{2} \lambda(t, v)\{P(\rho)-P(\rho(t, v))\}\right)\right.  \tag{3.59}\\
& \left.\quad+\frac{1}{2}(\partial \lambda(t, v),\{\widehat{c}(\rho)-\widehat{c}(\rho(t, v))\} \partial \lambda(t, v))\right] .
\end{align*}
$$

The corresponding error $\int_{0}^{T} Q_{N, \ell}^{L D}(\lambda(s), F ; G) d s$ integrated in $s$ will be denoted by $Q_{N, \ell, \delta}^{L D}(\lambda, F)$.
Theorem 3.11. Assume $\lambda \in C^{1,3}\left([0, T] \times \mathbb{T}^{d}\right), F \in \mathcal{F}_{0}^{d}$ and the conditions (3.4) and (3.24). Then, there exist $\delta_{0}, C>0$ such that for any $0<\delta<\delta_{0}, \beta>0$ and $1 \leq \ell \leq N / 2$, we have

$$
\begin{align*}
h_{N}(t) \leq & h_{N}(0)+\frac{K}{\delta} \int_{0}^{t} g(s) d s+\frac{K}{\delta} \int_{0}^{t} h_{N}(s) d s  \tag{3.60}\\
& +Q_{N, \ell, \beta, K}^{\Omega_{1}}(\lambda, F)+Q_{N, \ell, \delta}^{L D}(\lambda, F) \\
& +C(\beta+1)\|\partial \lambda\|_{\infty}^{2} \sup _{\rho \in[0,1]}\|R(\rho ; F)\|+Q_{N}^{E n}(\lambda, F)+Q_{N, \ell}^{\Omega_{2}}(\lambda, F) .
\end{align*}
$$

The estimate is uniform in $\lambda$ such that $\|\lambda\|_{\infty} \leq \lambda_{*}$ for each $\lambda_{*}>0$ as we noted in Lemma 3.8 .

See Section 5.1 for a summary of several error terms that appear in the estimate (3.60). In this theorem, it is not necessary that $\lambda$ is determined from the solution $\rho_{K}(t, v)$ of (1.11) as $\lambda(t, v)=\bar{\lambda}\left(\rho_{K}(t, v)\right)$. We assume this in Lemma 3.13 below.

Remark 3.2. Compared to Theorem 2.1 of [14], the term $K \sigma_{G}$, which results from the Glauber part, is new. Since $K \sigma_{G}$ and therefore $\sigma$ contains a diverging factor $K$, we change $\delta \cdot \sigma$ to $\frac{\delta}{K} \cdot \sigma$ in the definition of $g$. From this (and when applying the entropy inequality), we have $\frac{K}{\delta}$ in front of $\int_{0}^{t} g d s$ in the estimate in Theorem 3.11. The reason for having $\frac{K}{\delta}$ in front of $\int_{0}^{t} h_{N} d s$ in the estimate in Theorem 3.11 is that, when we apply the entropy inequality, we need to pay for $K$ in $K \sigma_{G}$ by the entropy factor; recall (3.53).

### 3.7 Proof of Proposition 2.1

The following lemma was shown in Lemma 2.1 of [14].

## Lemma 3.12.

$$
\inf _{F \in \mathcal{F}_{0}^{d}} \sup _{\rho \in[0,1]}\|R(\rho ; F)\|=0 .
$$

In fact, 9 improved the result of this lemma giving the decay rate in $n$ of $R(\rho ; F)$ approximated by $F$ satisfying $r(F) \leq n$; see (5.10) below.

The next lemma is shown in (2.6) in [14 when $K=0$. We can easily extend it to the case where $K \geq 1$, since we put $\frac{\delta}{K}$ in front of $\sigma$ in the definition of $g(t)$.
Lemma 3.13. Let $\rho(t, v) \equiv \rho_{K}(t, v)$ be the solution of the hydrodynamic equation (1.11) with $\rho_{0}$ satisfying the condition (1.12), and define $\lambda(t, v)$ as $\lambda(t, v)=\bar{\lambda}(\rho(t, v))$. Then, we have

$$
\begin{equation*}
g(t) \equiv g_{\delta_{*}, K}(t) \leq 0, \tag{3.61}
\end{equation*}
$$

by making $\delta_{*}>0$ small enough.
Proof. We first recall (3.58) to have

$$
\begin{equation*}
I(u ; \lambda(t, v)) \geq C\{u-\rho(t, v)\}^{2} \tag{3.62}
\end{equation*}
$$

for some $C>0$. Note that the large deviation rate function $I(u ; \lambda)$ is determined only from $\nu_{\lambda}$ and especially it doesn't depend on $K$.

On the other hand, we have $\sigma(\rho(t, v) ; t, v)=0$ and moreover, noting that $\frac{\partial}{\partial u} \sigma_{G}(\rho(t, v) ; t, v)=$ $\frac{1}{\chi(\rho(t, v))} f(\rho(t, v))$,

$$
\begin{align*}
\frac{\partial \sigma}{\partial u}(\rho(t, v) ; t, v) & =-\dot{\lambda}(t, v)+\operatorname{Tr}\left(\partial^{2} \lambda(t, v) D(\rho(t, v))\right)  \tag{3.63}\\
& +\frac{1}{2}\left(\partial \lambda(t, v), \hat{c}^{\prime}(\rho(t, v)) \partial \lambda(t, v)\right)+\frac{K}{\chi(\rho(t, v))} f(\rho(t, v))=0
\end{align*}
$$

where $\widehat{c}^{\prime}$ denotes the matrix obtained by differentiating each element of $\widehat{c}$ in $\rho$. In fact, one can easily recognize that (3.63) is equivalent to the hydrodynamic equation (1.11) itself by noting (3.52). Therefore, by Taylor's formula

$$
\sigma(u ; t, v)=\frac{1}{2} \frac{\partial^{2} \sigma}{\partial u^{2}}\left(u_{0} ; t, v\right)\{u-\rho(t, v)\}^{2}
$$

for some $u_{0} \in[0,1]$; note that (1.8) implies $\sigma \in C^{\infty}$ as a function of $u$. However, $\frac{\partial^{2}}{\partial u^{2}}(\sigma-$ $\left.K \sigma_{G}\right)(u ; t, v)$ is bounded on $[0,1] \times[0, T] \times \mathbb{T}^{d}$ and also independent of $K$, while

$$
\left|K \frac{\partial^{2} \sigma_{G}}{\partial u^{2}}(u ; t, v)\right|=\left|K \frac{\partial^{2}}{\partial u^{2}}\left[\left(\frac{\left\langle c^{+}\right\rangle_{u}}{\rho(t, v)}-\frac{\left\langle c^{-}\right\rangle_{u}}{1-\rho(t, v)}\right)\{u-\rho(t, v)\}\right]\right| \leq C_{1} K,
$$

for some $C_{1}>0$, since $0<c \leq \rho(t, v) \leq 1-c<1$ for some $c \in(0,1 / 2)$ by Lemma 7.1 below; also recall the comment below Lemma 3.8. Thus we obtain

$$
|\sigma(u ; t, v)| \leq\left(C_{1} K+C_{2}\right)\{u-\rho(t, v)\}^{2} .
$$

This combined with (3.62) completes the proof of (3.61) recalling $K \geq 1$.
Proof of Proposition 2.1. Proposition 2.1 follows from Theorem 3.11, Lemma 3.13 and a refined version of Lemma 3.12 given in (5.10) below. In fact, by (3.60) in Theorem 3.11 taking $F=F_{N}$ as in Proposition 2.1 (i.e., as in Section 5.2) (and $\lambda_{*}=\log (1-c) / c>0$ with $c$ in the proof of Lemma 3.13), and by Lemma 3.13 with $\delta_{*}>0$ sufficiently small, we have

$$
\begin{aligned}
h_{N}(t) \leq & h_{N}(0)+\frac{K}{\delta_{*}} \int_{0}^{t} h_{N}(s) d s+Q_{N, \ell, \beta, K}^{\Omega_{1}}\left(\lambda, F_{N}\right)+Q_{N, \ell, \delta_{*}}^{L D}\left(\lambda, F_{N}\right) \\
& +C(\beta+1)\|\partial \lambda\|_{\infty}^{2} \sup _{\rho \in[0,1]}\left\|R\left(\rho ; F_{N}\right)\right\|+Q_{N}^{E n}\left(\lambda, F_{N}\right)+Q_{N, \ell}^{\Omega_{2}}\left(\lambda, F_{N}\right) .
\end{aligned}
$$

Therefore, with the help of Gronwall's inequality, we have

$$
\begin{align*}
0 \leq h_{N}(t) \leq e^{K t / \delta_{*}} & \left(h_{N}(0)+Q_{N, \ell, \beta, K}^{\Omega_{1}}\left(\lambda, F_{N}\right)+Q_{N, \ell, \delta_{*}}^{L D}\left(\lambda, F_{N}\right)\right.  \tag{3.64}\\
& +C(\beta+1)\|\partial \lambda\|_{\infty}^{2} \sup _{\rho \in[0,1]}\left\|R\left(\rho ; F_{N}\right)\right\| \\
& \left.+Q_{N}^{E n}\left(\lambda, F_{N}\right)+Q_{N, \ell}^{\Omega_{2}}\left(\lambda, F_{N}\right)\right) .
\end{align*}
$$

Choosing $\beta=\beta(N), \ell=\ell(N), F_{N}, K=K(N)$ as in Section 5.2 below, we can show that each of the nine terms (recall that $Q_{N, \ell, \beta, K}^{\Omega_{1}}\left(\lambda, F_{N}\right)$ consists of four terms as in (3.47)) multiplied by $e^{K T / \delta_{*}}$ on the right-hand side of (3.64) is bounded by $\bar{C} N^{-\kappa}$ for some $\bar{C}=\bar{C}_{T}>0$ and $\kappa>0$. Therefore, we conclude $h_{N}(t) \leq C N^{-\kappa}, t \in[0, T]$ for $C=9 \bar{C}$.

### 3.8 Proof of Theorem 3.9

First we recall some known facts on thermodynamic functions; see [15] and Appendix B of [14] with $J \equiv 0, H_{\Lambda} \equiv 0$ and $R_{1}=0$. For a finite domain $\Lambda \Subset \mathbb{Z}^{d}(\Lambda \neq \emptyset)$, a chemical potential $\lambda \in \mathbb{R}$ and particle number $k: 0 \leq k \leq|\Lambda|$, define grand canonical and canonical partition functions by

$$
\begin{align*}
& Z_{\Lambda, \lambda}=\sum_{\eta_{\Lambda} \in \mathcal{X}_{\Lambda}} \exp \left\{\lambda \sum_{x \in \Lambda} \eta_{x}\right\}=e^{p(\lambda)|\Lambda|},  \tag{3.65}\\
& Z_{\Lambda, k}=\sum_{\eta_{\Lambda} \in \mathcal{X}_{\Lambda}: \sum_{x \in \Lambda} \eta_{x}=k} 1=\binom{|\Lambda|}{k}, \tag{3.66}
\end{align*}
$$

respectively, where $\mathcal{X}_{\Lambda}=\{0,1\}^{\Lambda}$ and recall (3.55) for $p(\lambda)$. Then,

$$
\begin{equation*}
\log Z_{\Lambda, k}=|\Lambda| q(k /|\Lambda|)+\frac{1}{2} \log \frac{|\Lambda|}{2 \pi k(|\Lambda|-k)}+o(1), \tag{3.67}
\end{equation*}
$$

as $|\Lambda|, k \rightarrow \infty$; recall (3.55) for $q(u)$. (Note, for $k=0$ or $|\Lambda|, Z_{\Lambda, 0}=Z_{\Lambda,|\Lambda|}=1$ and $q(0)=$ $q(1)=0$.) Indeed, by Stirling's formula $n!\sim n^{n} e^{-n} \sqrt{2 \pi n}\left(a_{n} \sim b_{n}\right.$ means $a_{n} / b_{n} \rightarrow 1$ as $n \rightarrow \infty$ ), we have

$$
\begin{aligned}
\log Z_{\Lambda, k}= & \log (|\Lambda|!/ k!(|\Lambda|-k)!) \\
= & |\Lambda| \log |\Lambda|-|\Lambda|+\frac{1}{2} \log 2 \pi|\Lambda|-\left\{k \log k-k+\frac{1}{2} \log 2 \pi k\right\} \\
& -\left\{(|\Lambda|-k) \log (|\Lambda|-k)-(|\Lambda|-k)+\frac{1}{2} \log 2 \pi(|\Lambda|-k)\right\}+o(1) \\
= & |\Lambda| \log |\Lambda|-k \log k-(|\Lambda|-k) \log (|\Lambda|-k)+\frac{1}{2} \log \frac{|\Lambda|}{2 \pi k(|\Lambda|-k)}+o(1) \\
= & |\Lambda|\left\{-\frac{k}{|\Lambda|} \log \frac{k}{|\Lambda|}-\left(1-\frac{k}{|\Lambda|}\right) \log \left(1-\frac{k}{|\Lambda|}\right)\right\}+\frac{1}{2} \log \frac{|\Lambda|}{2 \pi k(|\Lambda|-k)}+o(1),
\end{aligned}
$$

as $|\Lambda|, k \rightarrow \infty$, and this shows (3.67).
The functions $p(\lambda)$ and $-q(\rho)$ are continuous and convex, and satisfy

$$
\begin{align*}
p(\lambda) & =\sup _{\rho \in[0,1]}\{q(\rho)+\lambda \rho\},  \tag{3.68}\\
q(\rho) & =\inf _{\lambda \in \mathbb{R}}\{p(\lambda)-\lambda \rho\} . \tag{3.69}
\end{align*}
$$

For each $\rho \in[0,1]$, there exists a unique $\lambda=\bar{\lambda}(\rho) \in \overline{\mathbb{R}}:=\mathbb{R} \cup\{ \pm \infty\}$ such that

$$
\begin{equation*}
p(\lambda)=q(\rho)+\lambda \rho . \tag{3.70}
\end{equation*}
$$

Before proceeding to the proof of Theorem [3.9, we prepare a similar statement for finite volume Bernoulli measures with constant chemical potentials. For $\Lambda \Subset \mathbb{Z}^{d}(\Lambda \neq \emptyset)$, $\lambda \in \mathbb{R}$, the finite volume (grand canonical) Bernoulli measure $\nu_{\Lambda, \lambda}$ on $\Lambda$, which is a probability measure on $\mathcal{X}_{\Lambda}$, is defined by

$$
\begin{equation*}
\nu_{\Lambda, \lambda}(\eta)=Z_{\Lambda, \lambda}^{-1} \exp \left\{\lambda \sum_{x \in \Lambda} \eta_{x}\right\} \equiv \bar{\nu}_{\lambda}^{\otimes \Lambda}(\eta), \quad \eta \in \mathcal{X}_{\Lambda} . \tag{3.71}
\end{equation*}
$$

Proposition 3.14. For every $\lambda \in \mathbb{R}$ and $G(\rho)=G_{1}+\frac{1}{K} G_{2} \in C^{1}([0,1])$,

$$
\ell_{*}^{-d} \log E^{\nu_{\Lambda(\ell), \lambda}}\left[\exp \left\{\ell_{*}^{d} G\left(\bar{\eta}_{0}^{\ell}\right)\right\}\right]=\sup _{\rho \in[0,1]}\{G(\rho)-I(\rho ; \lambda)\}+Q_{\ell}(\lambda, G),
$$

recall $\Lambda(\ell)=\Lambda_{\ell, 0}$ in (3.1) and (3.22) for $\bar{\eta}_{0}^{\ell}$. We have an estimate for the error term $Q_{\ell}(\lambda, G)$, which is uniform in $\frac{1}{K} \in(0,1]$ :

$$
\begin{equation*}
\left|Q_{\ell}(\lambda, G)\right| \leq C \ell^{-d}\left(\log \ell+|\lambda|+\left\|G^{\prime}\right\|_{\infty}\right), \tag{3.72}
\end{equation*}
$$

where $G^{\prime} \equiv \partial_{\rho} G$.

Proof. By (3.65), setting $\bar{\eta}_{\Lambda}=\frac{1}{|\Lambda|} \sum_{x \in \Lambda} \eta_{x}$ for $\Lambda \subset \mathbb{Z}^{d}$ in general, we have

$$
\begin{aligned}
I & :=\frac{1}{|\Lambda|} \log E^{\nu_{\Lambda, \lambda}}\left[\exp \left\{|\Lambda| G\left(\bar{\eta}_{\Lambda}\right)\right\}\right] \\
& =\frac{1}{|\Lambda|} \log \left[\sum_{\eta \in \mathcal{X}_{\Lambda}} \exp \left\{\lambda \sum_{x \in \Lambda} \eta_{x}+|\Lambda| G\left(\bar{\eta}_{\Lambda}\right)\right\}\right]-\frac{1}{|\Lambda|} \log Z_{\Lambda, \lambda} \\
& =\frac{1}{|\Lambda|} \log \left[\sum_{m=0}^{|\Lambda|} Z_{\Lambda, m} \exp \{\lambda m+|\Lambda| G(m /|\Lambda|)\}\right]-p(\lambda) .
\end{aligned}
$$

Then we apply (3.67) for $Z_{\Lambda, m}$. First note that

$$
\begin{equation*}
\frac{4}{|\Lambda|} \leq \frac{|\Lambda|}{m(|\Lambda|-m)} \leq 2 \tag{3.73}
\end{equation*}
$$

for $1 \leq m \leq|\Lambda|-1,|\Lambda| \geq 2$. Therefore, by (3.67), $Z_{\Lambda, m} \leq e^{|\Lambda| q(m /|\Lambda|)+\frac{1}{2} \log \frac{2}{2 \pi}+C_{1}}$ for $0 \leq m \leq|\Lambda|,|\Lambda| \geq 2$ (including $m=0,|\Lambda|)$. Thus, denoting $a^{*}:=\sup _{\rho \in[0,1]}\{G(\rho)-$ $I(\rho ; \lambda)\}+p(\lambda)$ and estimating all terms in the sum in $m$ by using $a^{*}$, we have an upper bound of $I$ :

$$
\begin{aligned}
I & \leq \frac{1}{|\Lambda|} \log \left[(|\Lambda|+1) \exp \left\{|\Lambda| a^{*}+C_{2}\right\}\right]-p(\lambda) \\
& =\frac{1}{|\Lambda|}\left[\log (|\Lambda|+1)+|\Lambda| a^{*}+C_{2}\right]-p(\lambda) \\
& \leq a^{*}-p(\lambda)+\frac{C}{|\Lambda|} \log |\Lambda|
\end{aligned}
$$

(Note that the constant $C$ is uniform in $G$; indeed, $C=2$ is enough for large $|\Lambda|$.)
Next, we show the lower bound for $I$. The supremum for $a^{*}$ is attained at some $\rho_{*} \in[0,1]$. (Note that $q$ is concave and $q(0)=q(1)=0$, and $q^{\prime}(\rho)=\log (1-\rho) / \rho$ so that $q^{\prime}(0)=+\infty, q^{\prime}(1)=-\infty$.) Since $G \in C^{1}([0,1])$, choosing $m$ such that $\frac{m}{|\Lambda|}$ is close to $\rho_{*}$ in the sense that $\left|\frac{m}{|\Lambda|}-\rho_{*}\right| \leq \frac{1}{|\Lambda|}$ and $\frac{m}{|\Lambda|} \leq \rho_{*}$ (if $\rho_{*} \leq \frac{1}{2}$ ) or $\frac{m}{|\Lambda|} \geq \rho_{*}$ (if $\rho_{*}>\frac{1}{2}$ ), we have

$$
\left|\left\{G\left(\rho_{*}\right)-I\left(\rho_{*} ; \lambda\right)\right\}-\{G(m /|\Lambda|)-I(m /|\Lambda| ; \lambda)\}\right| \leq \frac{\left\|G^{\prime}\right\|_{\infty}+|\lambda|}{|\Lambda|}+\left|q\left(\rho_{*}\right)-q(m /|\Lambda|)\right|
$$

Here, $\left|q\left(\rho_{*}\right)-q(m /|\Lambda|)\right|$ is estimated as

$$
\left|q\left(\rho_{*}\right)-q(m /|\Lambda|)\right| \leq \frac{C_{3}}{|\Lambda|}
$$

for some $C_{3}=C_{3}(\varepsilon)>0$ if $0<\varepsilon \leq \rho_{*} \leq 1-\varepsilon<1$. If $0<\rho_{*} \leq \varepsilon$, since $\frac{m}{|\Lambda|} \leq \rho_{*}$, we have $\left|q^{\prime}\left(\frac{m}{|\Lambda|}\right)\right| \geq\left|q^{\prime}(\rho)\right|$ for every $\rho \in\left[m /|\Lambda|, \rho_{*}\right]$ and therefore

$$
\left|q\left(\rho_{*}\right)-q(m /|\Lambda|)\right| \leq \frac{1}{|\Lambda|}\left|q^{\prime}\left(\frac{m}{|\Lambda|}\right)\right|=\frac{1}{|\Lambda|} \log \frac{|\Lambda|-m}{m} \leq \frac{1}{|\Lambda|} \log |\Lambda| .
$$

The case $1>\rho_{*} \geq 1-\varepsilon$ is similar.

Then, taking only the term given by this $m$ in the sum of $I$ and using the lower bound in (3.73) for $Z_{\Lambda, m}$, we have

$$
\begin{aligned}
I & \geq \frac{1}{|\Lambda|} \log \left[\exp \left\{|\Lambda|\left(a^{*}-\frac{\left\|G^{\prime}\right\|_{\infty}+|\lambda|+C_{3}+\log |\Lambda|}{|\Lambda|}\right)+\frac{1}{2} \log \frac{4}{2 \pi|\Lambda|}\right\}\right]-p(\lambda) \\
& =a^{*}-\frac{\left\|G^{\prime}\right\|_{\infty}+|\lambda|+C_{3}+\log |\Lambda|}{|\Lambda|}-\frac{\log |\Lambda|-\log \frac{2}{\pi}}{2|\Lambda|}-p(\lambda) \\
& \geq a^{*}-p(\lambda)-\frac{C}{|\Lambda|}\left(\log |\Lambda|+|\lambda|+\left\|G^{\prime}\right\|_{\infty}\right)
\end{aligned}
$$

We therefore have the conclusion with the estimate (3.72) by taking $\Lambda=\Lambda(\ell)$.
We are now ready to give the proof of Theorem 3.9, As we noted, this theorem is an extension of Theorem 3.3 of [14] and gives a further error estimate. Because the definition of $\widetilde{G}$ is different, the proof is modified by applying Hölder's inequality.

Proof of Theorem 3.9. To apply Proposition 3.14 by localizing in space, finally to obtain the estimate in terms of a spatial integral and also to match with the scale $\ell$ in $\widetilde{G}$, we divide $\mathbb{T}_{N}^{d}$ into disjoint boxes $\left\{\Lambda_{\ell, a}\right\}_{a}$ with side length $\ell_{*}=2 \ell+1$ and centered at $a \in$ $\ell_{*} \mathbb{T}_{N / \ell_{*}}^{d}=\left\{\ell_{*}, 2 \ell_{*}, \ldots, N\right\}^{d}$, assuming $N / \ell_{*} \in \mathbb{N}$ for simplicity (if not, we may make the side lengths of some of the boxes smaller or larger by 1 ).

Since $x \in \mathbb{T}_{N}^{d}$ is uniquely decomposed as $x=y+a$ with $y \in \Lambda(\ell)=\Lambda_{\ell, 0}$ and $a \in \ell_{*} \mathbb{T}_{N / \ell_{*}}^{d}$ (we write $a(x)$ for $a$ ) according to this division, writing the sum and the product in $a \in \ell_{*} \mathbb{T}_{N / \ell_{*}}^{d}$ by $\sum_{a}^{*}$ and $\prod_{a}^{*}$, respectively, we have

$$
\begin{aligned}
I & :=E^{\nu_{\lambda(\cdot), F}^{N}}[\exp \widetilde{G}(\eta)] \\
& \left.=Z_{\lambda(\cdot), F, N}^{-1} E^{\nu^{N}}\left[\exp \left\{\sum_{y \in \Lambda(\ell)} \sum_{a}^{*}\left[G(y+a) / N, \bar{\eta}_{y+a}^{\ell}\right)+\lambda(a / N) \bar{\eta}_{y+a}^{\ell}\right]+R(\eta)\right\}\right] \\
& =Z_{\lambda(\cdot), F, N}^{-1} E^{\nu^{N}}\left[\prod_{y \in \Lambda(\ell)} \exp \left\{\sum_{a}^{*}\left[G\left((y+a) / N, \bar{\eta}_{y+a}^{\ell}\right)+\lambda(a / N) \bar{\eta}_{y+a}^{\ell}\right]\right\} \cdot e^{R(\eta)}\right] \\
& \leq e^{\|R\|_{\infty}} Z_{\lambda(\cdot), F, N}^{-1} \prod_{y \in \Lambda(\ell)} E^{\nu^{N}}\left[\exp \left\{\ell_{*}^{d} \sum_{a}^{*}\left[G\left((y+a) / N, \bar{\eta}_{y+a}^{\ell}\right)+\lambda(a / N) \bar{\eta}_{y+a}^{\ell}\right]\right\}\right]^{1 / \ell_{*}^{d}}
\end{aligned}
$$

where $R(\eta)=R_{1}+R_{2}$ and

$$
\begin{aligned}
R_{1} & =\frac{1}{N} \sum_{x \in \mathbb{T}_{N}^{d}}\left(\partial \lambda(x / N), \tau_{x} F(\eta)\right) \\
R_{2} & =\sum_{x \in \mathbb{T}_{N}^{d}}\left(\lambda(x / N) \eta_{x}-\lambda(a(x) / N) \bar{\eta}_{x}^{\ell}\right)
\end{aligned}
$$

For the last line, we have first estimated $e^{R} \leq e^{\|R\|_{\infty}}$ and then applied Hölder's inequality under $\nu^{N}$. Two error terms $R_{1}$ and $R_{2}$ are estimated as follows:

$$
\begin{equation*}
\left|R_{1}(\eta)\right| \leq N^{d-1}\|\partial \lambda\|_{\infty}\|F\|_{\infty}, \quad\left|R_{2}(\eta)\right| \leq \ell_{*} N^{d-1}\|\partial \lambda\|_{\infty} \tag{3.74}
\end{equation*}
$$

In fact, for $R_{2}$, note that the sum of the second term of $R_{2}$ can be rewritten as

$$
\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(a(x) / N) \ell_{*}^{-d} \sum_{z \in \Lambda(\ell)} \eta_{x+z}=\sum_{x^{\prime} \in \mathbb{T}_{N}^{d}} \eta_{x^{\prime}} \ell_{*}^{-d} \sum_{z \in \Lambda(\ell)} \lambda\left(a\left(x^{\prime}-z\right) / N\right)
$$

Since $\bar{\eta}_{y+a}^{\ell}$ are functions of $\left.\eta\right|_{\Lambda_{\ell, y+a}}$, they are independent for different $a$ under $\nu^{N}$. Therefore, the last expectation in the bound for $I$ is factorized and is rewritten as

$$
\begin{aligned}
& E^{\nu^{N}}\left[\exp \left\{\ell_{*}^{d} \sum_{a}^{*}\left[G\left((y+a) / N, \bar{\eta}_{y+a}^{\ell}\right)+\lambda(a / N) \bar{\eta}_{y+a}^{\ell}\right]\right\}\right] \\
& =\prod_{a}^{*} E^{\nu^{N}}\left[\exp \left\{\ell_{*}^{d}\left[G\left((y+a) / N, \bar{\eta}_{y+a}^{\ell}\right)+\lambda(a / N) \bar{\eta}_{y+a}^{\ell}\right]\right\}\right] \\
& =\prod_{a}^{*}\left(Z_{\Lambda_{\ell, y+a}, \lambda(a / N)} \cdot 2^{-\ell_{*}^{d}}\right) E^{\nu_{\Lambda, y+a}, \lambda(a / N)}\left[\exp \left\{\ell_{*}^{d} G\left((y+a) / N, \bar{\eta}_{y+a}^{\ell}\right)\right\}\right] .
\end{aligned}
$$

In the second line, $\nu^{N}$ can be replaced by $\bar{\nu}_{1 / 2}^{\otimes \Lambda_{\ell, y+a}}$ and, recalling (3.71), we obtain the third line. Thus, noting the shift-invariance of $Z_{\Lambda, \lambda}$ and $\nu_{\Lambda, \lambda}$ in $\Lambda$, and $\prod_{y} \prod_{a}^{*}=\prod_{x}$, we have

$$
I \leq e^{\|R\|_{\infty}} Z_{\lambda(\cdot), F, N}^{-1} \prod_{a}^{*} Z_{\Lambda(\ell), \lambda(a / N)} \cdot 2^{-\ell_{*}^{d}} \times \prod_{x \in \mathbb{T}_{N}^{d}} E^{\nu_{\Lambda(\ell), \lambda(a(x) / N)}}\left[\exp \left\{\ell_{*}^{d} G\left(x / N, \bar{\eta}_{0}^{\ell}\right)\right\}\right]^{1 / \ell_{*}^{d}}
$$

and therefore,

$$
\begin{align*}
N^{-d} \log I \leq & N^{-d}\|R\|_{\infty}+N^{-d} \log \left(Z_{\lambda(\cdot), F, N}^{-1} \prod_{a}^{*} Z_{\Lambda(\ell), \lambda(a / N)} \cdot 2^{-\ell_{*}^{d}}\right)  \tag{3.75}\\
& +N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \ell_{*}^{-d} \log E^{\nu_{\Lambda(\ell), \lambda(a(x) / N)}}\left[\exp \left\{\ell_{*}^{d} G\left(x / N, \bar{\eta}_{0}^{\ell}\right)\right\}\right]
\end{align*}
$$

For the partition functions, recalling that

$$
\begin{aligned}
& Z_{\Lambda, \lambda} \cdot 2^{-|\Lambda|}=E^{\bar{\nu}_{1 / 2}^{\otimes \Lambda}}\left[\exp \left\{\lambda \sum_{x \in \Lambda} \eta_{x}\right\}\right], \quad \lambda \in \mathbb{R} \\
& Z_{\lambda(\cdot), F, N}=E^{\nu^{N}}\left[\exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(x / N) \eta_{x}+R_{1}(\eta)\right\}\right],
\end{aligned}
$$

and changing $\Lambda(\ell)$ to $\Lambda_{\ell, a}$ in $Z_{\Lambda(\ell), \lambda(a / N)}$, we obtain

$$
\prod_{a}^{*} Z_{\Lambda_{\ell, a}, \lambda(a / N)} \cdot 2^{-\ell_{*}^{d}}=Z_{\widetilde{\lambda}(\cdot), 0, N}
$$

where $\widetilde{\lambda}(v)=\sum_{a}^{*} \lambda(a / N) 1_{\Lambda_{\ell, a}}(N v)$ is a step function on $\mathbb{T}^{d}$ and $F=0$ on the right-hand side. To replace the step function $\widetilde{\lambda}(\cdot)$ with the original function $\lambda(\cdot)$, note that

$$
\frac{Z_{\widetilde{\lambda}(\cdot), 0, N}}{Z_{\lambda(\cdot), 0, N}}=\frac{E^{\nu_{N}}\left[\exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \widetilde{\lambda}(x / N) \eta_{x}\right\}\right]}{E^{\nu_{N}}\left[\exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(x / N) \eta_{x}\right\}\right]}
$$

$$
\begin{aligned}
& =\frac{E^{\nu_{N}}\left[\exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(x / N) \eta_{x}+\sum_{x \in \mathbb{T}_{N}^{d}}(\widetilde{\lambda}(x / N)-\lambda(x / N)) \eta_{x}\right\}\right]}{E^{\nu_{N}}\left[\exp \left\{\sum_{x \in \mathbb{T}_{N}^{d}} \lambda(x / N) \eta_{x}\right\}\right]} \\
& \leq e^{\ell N^{d-1}\|\partial \lambda\|_{\infty}} .
\end{aligned}
$$

To compare two partition functions with and without $F$, we have

$$
\frac{Z_{\lambda(\cdot), 0, N}}{Z_{\lambda(\cdot), F, N}} \leq e^{\left\|R_{1}\right\|_{\infty}}
$$

Summarizing these and noting (3.74), we have shown for first two terms in (3.75) that

$$
\begin{align*}
N^{-d}\|R\|_{\infty} & +N^{-d} \log \left(Z_{\lambda(\cdot), F, N}^{-1} \prod_{a}^{*} Z_{\Lambda(\ell), \lambda(a / N)} \cdot 2^{-\ell_{*}^{d}}\right)  \tag{3.76}\\
& \leq C N^{-1}\|\partial \lambda\|_{\infty}\left(\ell+\|F\|_{\infty}\right) .
\end{align*}
$$

For the last term of (3.75), one can apply Proposition 3.14 to see that

$$
\begin{aligned}
N^{-d} & \sum_{x \in \mathbb{T}_{N}^{d}} \ell_{*}^{-d} \log E^{\nu_{\Lambda(\ell), \lambda(a(x) / N)}}\left[\exp \left\{\ell_{*}^{d} G\left(x / N, \vec{\eta}_{0}^{\ell}\right)\right\}\right] \\
& =N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}}\left\{\sup _{\rho \in[0,1]}\{G(x / N, \rho)-I(\rho ; \lambda(a(x) / N))\}+Q_{\ell}(\lambda(a(x) / N), G(x / N, \cdot))\right\},
\end{aligned}
$$

and

$$
\begin{equation*}
\left|Q_{\ell}(\lambda(a(x) / N), G(x / N, \cdot))\right| \leq \frac{C}{\ell^{d}}\left(\log \ell+\|\lambda\|_{\infty}+\left\|\partial_{\rho} G_{1}\right\|_{\infty}+\left\|\partial_{\rho} G_{2}\right\|_{\infty}\right) . \tag{3.77}
\end{equation*}
$$

Moreover, one can estimate

$$
\begin{equation*}
N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} \sup _{\rho \in[0,1]}\{G(x / N, \rho)-I(\rho ; \lambda(a(x) / N))\} \leq \sup _{\rho: s t e p ~ o n ~}^{\mathbb{T}^{d}} \mid \mathbb{G}(\rho)+Q_{\ell, N}, \tag{3.78}
\end{equation*}
$$

where the supremum on the right-hand side is taken over all step functions $\rho(v)$ on $\mathbb{T}^{d}$,

$$
\begin{equation*}
Q_{\ell, N} \equiv Q_{\ell, N}(\lambda ; G)=\frac{2 \ell}{N}\left(\|\partial \lambda\|_{\infty}+\left\|\partial_{v} G_{1}\right\|_{\infty}+\left\|\partial_{v} G_{2}\right\|_{\infty}\right) \tag{3.79}
\end{equation*}
$$

and

$$
\mathbb{G}(\rho)=\int_{\mathbb{T}^{d}}\{G(v, \rho(v))-I(\rho(v) ; \lambda(v))\} d v,
$$

for $\rho \in L^{1}\left(\mathbb{T}^{d} ;[0,1]\right)$. Indeed, we first replace $G(x / N, \rho)$ in (3.78) by $G(a(x) / N, \rho)$ with an error within $\ell N^{-1}\left(\left\|\partial_{v} G_{1}\right\|_{\infty}+\left\|\partial_{v} G_{2}\right\|_{\infty}\right)$, and then the supremum is attained at some $\rho(a(x) / N)$ for each $a=a(x)$. This defines a step function $\rho(v)=\sum_{a}^{*} \rho(a / N) 1_{\Lambda_{\ell, a}}(N v)$, and leads to the functional $\mathbb{G}(\rho)$, but with an discretization also for $G$ and $\lambda$ in the variable $v$. The error of removing these discretization in $G$ and $\lambda$ is estimated by using

$$
\sup _{\left|v_{1}-v_{2}\right| \leq \ell / N}\left|\lambda\left(v_{1}\right)-\lambda\left(v_{2}\right)\right| \leq \ell N^{-1}\|\partial \lambda\|_{\infty},
$$

$$
\begin{aligned}
& \sup _{\left|v_{1}-v_{2}\right| \leq \ell / N} \sup _{\rho \in[0,1]}\left|G\left(v_{1}, \rho\right)-G\left(v_{2}, \rho\right)\right| \leq \ell N^{-1}\left(\left\|\partial_{v} G_{1}\right\|_{\infty}+\left\|\partial_{v} G_{2}\right\|_{\infty}\right) \\
& \left|\int_{\mathbb{T}^{d}} p(\lambda(v)) d v-N^{-d} \sum_{x \in \mathbb{T}_{N}^{d}} p(\lambda(a(x) / N))\right| \leq \ell N^{-1}\left\|p^{\prime}\right\|_{\infty}\|\partial \lambda\|_{\infty} \leq \ell N^{-1}\|\partial \lambda\|_{\infty}
\end{aligned}
$$

and obtain (3.78) with $Q_{\ell, N}$ given by (3.79).
Since $\mathbb{G}(\rho)$ is continuous in $\rho \in L^{1}\left(\mathbb{T}^{d} ;[0,1]\right)$ and $C\left(\mathbb{T}^{d} ;[0,1]\right)$ is dense in $L^{1}\left(\mathbb{T}^{d} ;[0,1]\right)$, we obtain the conclusion of the theorem from (3.76), (3.77), (3.78) and (3.79).

## 4 Error estimates for the CLT variances

We now give the error estimates for the variational quantity appearing in Lemma 3.6, which is sometimes called the central limit theorem (CLT) variance; recall also the error term $Q_{\ell}^{(2)}(\lambda, F)$ in Theorem 3.5. Recall that this quantity is defined by means of the localized Kawasaki generator $L_{\Lambda(\ell), \zeta}$ given in (3.32) and defined on the box $\Lambda(\ell)=\Lambda_{\ell, 0}$ centered at 0 , where we denoted $\zeta=\left.\eta\right|_{\Lambda(\ell)^{c}}$ and $\xi=\left.\eta\right|_{\Lambda(\ell)}$ for $\eta \in \mathcal{X}$. In particular, the Glauber part plays no role and the arguments in Sections 4 (characterization of closed forms) and 5 (computation of variances) of [14] are valid as is in our setting.

However, these are not sufficient for our purpose to derive appropriate decay rates for the error terms. In particular, for the CLT variance of $A_{\ell}$, a qualitative convergence result as $\ell \rightarrow \infty$ (see (4.8) below) is known and shown based on the characterization of the closed forms, initiated by Varadhan [28] for the Ginzburg-Landau type model. But, this is weak for our purpose and, to fill the gap, Theorem 4.2 below was shown in 9 ] by a new technique inspired by the method of the quantitative homogenization. This theorem provides an appropriate decay rate of the CLT variance of $A_{\ell}$ and, in particular, the characterization of the closed forms was not used for the proof of this theorem.

For $f, g: \mathcal{X}_{\Lambda(\ell), m} \rightarrow \mathbb{R}$ which satisfy $\langle f\rangle_{\Lambda(\ell), m}=\langle g\rangle_{\Lambda(\ell), m}=0$, we define

$$
\begin{aligned}
& \Delta_{\ell, m, \zeta}(f, g)=\left\langle f\left(-L_{\Lambda(\ell), \zeta}\right)^{-1} g\right\rangle_{\Lambda(\ell), m} \\
& \Delta_{\ell, m, \zeta}(f)=\Delta_{\ell, m, \zeta}(f, f)
\end{aligned}
$$

where $m \in\left[0, \ell_{*}^{d}\right] \cap \mathbb{Z}$ and $\zeta \in \mathcal{X}_{\Lambda(\ell)^{c}}$. Recall three $\mathbb{R}^{d}$-valued functions $A_{\ell}, B_{\ell}$ and $H_{\ell}$, which are defined by (3.35), (3.36), and (3.37), respectively, and $n=r(F)+1$ in $H_{\ell}$.

Proposition 4.1. For $F \in \mathcal{F}_{0}^{d}$ and $\theta, \tilde{\theta} \in \mathbb{R}^{d}:|\theta|=|\tilde{\theta}|=1$, set

$$
\begin{aligned}
Q_{\ell}^{(4)}(F) & \equiv Q_{\ell}^{(4)}(F ; \theta, m, \zeta)=\ell_{*}^{-d} \Delta_{\ell, m, \zeta}\left(\theta \cdot\left(B_{\ell, \zeta}-H_{\ell, \zeta, F}\right)\right)-\frac{1}{2} \theta \cdot \widehat{c}\left(m / \ell_{*}^{d} ; F\right) \theta \\
Q_{\ell}^{(5)}(F) & \equiv Q_{\ell}^{(5)}(F ; \theta, \tilde{\theta}, m, \zeta)=\ell_{*}^{-d} \Delta_{\ell, m, \zeta}\left(\tilde{\theta} \cdot A_{\ell}, \theta \cdot\left(B_{\ell, \zeta}-H_{\ell, \zeta, F}\right)\right)-(\theta \cdot \tilde{\theta}) \chi\left(m / \ell_{*}^{d}\right)
\end{aligned}
$$

Then, we have

$$
\begin{align*}
& \left|Q_{\ell}^{(4)}(F)\right| \leq C r(F)^{d}\left(1+\|F\|_{0, \infty}^{2}\right) \ell^{-1}  \tag{4.1}\\
& \left|Q_{\ell}^{(5)}(F)\right| \leq C r(F)^{2 d}\|F\|_{\infty} \ell^{-d}+C \ell^{-1} \tag{4.2}
\end{align*}
$$

uniformly in $\theta, \tilde{\theta} \in \mathbb{R}^{d}:|\theta|=|\tilde{\theta}|=1, m \in\left[0, \ell_{*}^{d}\right] \cap \mathbb{Z}$ and $\zeta \in \mathcal{X}_{\Lambda(\ell)}$, where $\theta \cdot \tilde{\theta}$ stands for the inner product of $\theta$ and $\tilde{\theta} \in \mathbb{R}^{d}$ which has been denoted by $(\theta, \tilde{\theta})$ in the previous sections.

Proof. We use the following two identities shown in the proof of Proposition 5.1 of [14]:

$$
\begin{align*}
& \ell_{*}^{-d} \Delta_{\ell, m, \zeta}\left(\theta \cdot\left(B_{\ell}-H_{\ell}\right)\right)  \tag{4.3}\\
& =\frac{1}{2} \ell_{*}^{-d} \sum_{b=\tau_{x} e_{i}^{*} \in(\Lambda(\ell))^{*}}\left\langle c_{b}\left[\theta \cdot e_{i}\left(\xi_{x+e_{i}}-\xi_{x}\right)-\pi_{b}\left(\sum_{y \in \Lambda(\ell-n)} \tau_{y} F \cdot \theta\right)\right]^{2}\right\rangle_{\Lambda(\ell), m},
\end{align*}
$$

and

$$
\begin{align*}
& \ell_{*}^{-d} \Delta_{\ell, m, \zeta}\left(\tilde{\theta} \cdot A_{\ell}, \theta \cdot\left(B_{\ell}-H_{\ell}\right)\right)  \tag{4.4}\\
& =\ell_{*}^{-d}\left\langle\left\{\sum_{i=1}^{d} \tilde{\theta}_{i} \sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}} \tau_{y} \Psi_{i}\right\}\left\{\sum_{x \in \Lambda(\ell)}(\theta \cdot x) \xi_{x}+\sum_{x \in \Lambda(\ell-n)} \tau_{x}(\theta \cdot F)\right\}\right\rangle_{\Lambda(\ell), m} \\
& =\ell_{*}^{-d} \sum_{i=1}^{d} \tilde{\theta}_{i} \sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}} \sum_{x \in \Lambda(\ell)}\left\langle\tau_{y} \Psi_{i}\left\{(\theta \cdot x) \xi_{x}+1_{x \in \Lambda(\ell-n)} \tau_{x}(\theta \cdot F)\right\}\right\rangle_{\Lambda(\ell), m} .
\end{align*}
$$

To show (4.1), we first replace the expectation on the right-hand side of (4.3) under the canonical equilibrium measure $\nu_{\Lambda(\ell), m}$ by that under the grandcanonical equilibrium measure $\nu_{\rho}$ with $\rho=m / \ell_{*}^{d}$ :

$$
\begin{equation*}
\frac{1}{2} \ell_{*}^{-d} \sum_{b=\tau_{x} e_{i}^{*} \in(\Lambda(\ell))^{*}}\left\langle c_{b}\left[\theta \cdot e_{i}\left(\xi_{x+e_{i}}-\xi_{x}\right)-\pi_{b}\left(\sum_{y \in \Lambda(\ell-n)} \tau_{y} F \cdot \theta\right)\right]^{2}\right\rangle\left(m / \ell_{*}^{d}\right) \tag{4.5}
\end{equation*}
$$

By the equivalence of ensembles (3.27) (with $\left.|\Delta| \leq r(F)^{d}\right)$ and recalling $|\theta|=1$, the error for this replacement is bounded by

$$
C r(F)^{d}\left(1+\|F\|_{0, \infty}^{2}\right) \ell^{-d}
$$

Then, if $b=\tau_{x} e_{i}^{*} \in(\Lambda(\ell-2 n))^{*}$, the sum in $y \in \Lambda(\ell-n)$ in (4.5) can be replaced by the sum in $y \in \mathbb{Z}^{d}$, Thus, by the translation invariance of $\nu_{\rho}$, (4.5) is equal to

$$
\begin{aligned}
& \frac{1}{2} \ell_{*}^{-d} \sum_{i=1}^{d} \sharp\left\{b \in(\Lambda(\ell-2 n))^{*}: i \text { th directed }\right\} \\
& \\
& \quad \times\left\langle c_{e_{i}^{*}}\left[\theta \cdot e_{i}\left(\xi_{e_{i}}-\xi_{0}\right)-\pi_{e_{i}^{*}}\left(\sum_{y \in \mathbb{Z}^{d}} \tau_{y} F \cdot \theta\right)\right]^{2}\right\rangle\left(m / \ell_{*}^{d}\right),
\end{aligned}
$$

with an error bounded by

$$
C\left(1+\|F\|_{0, \infty}^{2}\right) \frac{\left|(\Lambda(\ell))^{*} \backslash(\Lambda(\ell-2 n))^{*}\right|}{\ell_{*}^{d}} \leq C^{\prime}\left(1+\|F\|_{0, \infty}^{2}\right) n \ell^{-1}
$$

Finally, noting that $\sharp\left\{b \in(\Lambda(\ell-2 n))^{*}: i\right.$ th directed $\} / \ell_{*}^{d}=\frac{(2(\ell-2 n))^{d}}{(2 \ell+1)^{d}}=1+O\left(\frac{n}{\ell}\right)$ and recalling $n=r(F)+1$, the above expression can be replaced by

$$
\begin{equation*}
\frac{1}{2} \sum_{i=1}^{d}\left\langle c_{e_{i}^{*}}\left[\theta \cdot e_{i}\left(\xi_{e_{i}}-\xi_{0}\right)-\pi_{e_{i}^{*}}\left(\sum_{y \in \mathbb{Z}^{d}} \tau_{y} F \cdot \theta\right)\right]^{2}\right\rangle\left(m / \ell_{*}^{d}\right), \tag{4.6}
\end{equation*}
$$

with an error bounded by

$$
C r(F)\left(1+\|F\|_{0, \infty}^{2}\right) \ell^{-1}
$$

However, by the identity at the bottom of p. 22 of [14], (4.6) is equal to $\frac{1}{2} \theta \cdot \widehat{c}\left(m / \ell_{*}^{d} ; F\right) \theta$ and we obtain the estimate (4.1).

To show (4.2), we first note the exchangeability under the canonical measure $\nu_{\Lambda(\ell), m}$, that is, $\eta$ and $\eta^{x, y}$ have the same distributions under $\nu_{\Lambda(\ell), m}$ for $x, y \in \Lambda(\ell), x \neq y$. This is easily seen from the uniformity of $\nu_{\Lambda(\ell), m}$ or the invariance of $\sum_{z \in \Lambda(\ell)} \eta_{z}$ under the transform $\eta \mapsto \eta^{x, y}$. In the expression (4.4), the right-hand side looks like $O\left(\ell^{2 d} / \ell^{d}\right)$, but due to the exchangeability under $\eta \mapsto \eta^{y, y+e_{i}}$, we have

$$
\left\langle\tau_{y} \Psi_{i} \xi_{x}\right\rangle_{\Lambda(\ell), m}=\left\langle\left(\eta_{y+e_{i}}-\eta_{y}\right) \xi_{x}\right\rangle_{\Lambda(\ell), m}=0
$$

if $x \neq y, y+e_{i}$ and

$$
\left\langle\tau_{y} \Psi_{i} \tau_{x}(\theta \cdot F)\right\rangle_{\Lambda(\ell), m}=0
$$

if $y, y+e_{i} \notin \tau_{x}(\operatorname{supp} F)$, i.e., $y-x, y-x+e_{i} \notin \operatorname{supp} F$, especially, if $|y-x| \geq r(F)+1$.
In particular, the first part of the sum (4.4) (related to $\xi_{x}$ ) is equal to

$$
\begin{aligned}
\ell_{*}^{-d} & \sum_{i=1}^{d} \tilde{\theta}_{i} \sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}}\left\langle\tau_{y} \Psi_{i}\left\{(\theta \cdot y) \xi_{y}+\left(\theta \cdot y+e_{i}\right) \xi_{y+e_{i}}\right\}\right\rangle_{\Lambda(\ell), m} \\
& =\ell_{*}^{-d} \sum_{i=1}^{d} \tilde{\theta}_{i} \sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}}\left\{-(\theta \cdot y)+\left(\theta \cdot y+e_{i}\right)\right\} \chi_{\Lambda(\ell), m} \\
& =\frac{(2 \ell)^{d}}{(2 \ell+1)^{d}}(\tilde{\theta} \cdot \theta) \chi_{\Lambda(\ell), m},
\end{aligned}
$$

by noting that both $x=y$ and $y+e_{i}$ satisfy $x \in \Lambda(\ell)$ and then recalling the uniformity of $\nu_{\Lambda(\ell), m}$, where

$$
\chi_{\Lambda(\ell), m}:=-\left\langle\Psi_{i} \xi_{0}\right\rangle_{\Lambda(\ell), m}\left(=-\left\langle\left(\xi_{e_{i}}-\xi_{0}\right) \xi_{0}\right\rangle_{\Lambda(\ell), m}\right) .
$$

However, by the equivalence of ensembles (3.27), we have

$$
\left|\chi_{\Lambda(\ell), m}-\chi\left(m / \ell_{*}^{d}\right)\right| \leq C \ell^{-d} .
$$

Therefore, the first part of the sum (4.4) behaves as

$$
(\tilde{\theta} \cdot \theta) \chi\left(m / \ell_{*}^{d}\right)+O(1 / \ell)
$$

On the other hand, as we pointed out above, the second part of the sum (4.4) (related to $F$ ) can be restricted to the terms of $x \in \Lambda(\ell):|x-y| \leq r(F)$. Then, applying the
equivalence of ensembles (3.27) (with $\left.|\Delta| \leq r(F)^{d}\right)$, we can replace it by

$$
\begin{equation*}
\ell_{*}^{-d} \sum_{i=1}^{d} \tilde{\theta}_{i} \sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}} \sum_{x \in \Lambda(\ell):|x-y| \leq r(F)}\left\langle\tau_{y} \Psi_{i} 1_{x \in \Lambda(\ell-n)} \tau_{x}(\theta \cdot F)\right\rangle\left(m / \ell_{*}^{d}\right) \tag{4.7}
\end{equation*}
$$

with an error bounded by

$$
C r(F)^{2 d}\|F\|_{\infty} \ell^{-d} .
$$

Denoting $\rho=m / \ell_{*}^{d}$, since $\left\langle\tau_{y} \Psi_{i} \tau_{x}(\theta \cdot F)\right\rangle_{\rho}=0$ if $|x-y| \geq r(F)+1$, we can drop the condition $|x-y| \leq r(F)$ in the sum (4.7) and obtain for each $i$

$$
\begin{aligned}
& \ell_{*}^{-d} \sum_{y: \tau \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}} \sum_{x \in \Lambda(\ell-n):|x-y| \leq r(F)}\left\langle\tau_{y} \Psi_{i} \tau_{x}(\theta \cdot F)\right\rangle_{\rho} \\
& \quad=\ell_{*}^{-d} \sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}} \sum_{x \in \Lambda(\ell-n)}\left\langle\tau_{y} \Psi_{i} \tau_{x}(\theta \cdot F)\right\rangle_{\rho}=0 .
\end{aligned}
$$

Here, to see that the last sum vanishes, we first observe

$$
\sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}} \tau_{y} \Psi_{i}=\sum_{y: \tau_{y} e_{i}^{*} \in(\Lambda(\ell))^{*}}\left(\eta_{y+e_{i}}-\eta_{y}\right)=\sum_{z_{+} \in \partial_{+}^{i} \Lambda(\ell)} \eta_{z_{+}}-\sum_{z_{-} \in \partial_{-}^{i} \Lambda(\ell)} \eta_{z_{-}},
$$

where $\partial_{ \pm}^{i} \Lambda(\ell)=\left\{z=\left(z_{j}\right)_{j=1}^{d} ; z_{i}= \pm \ell,\left|z_{j}\right| \leq \ell(j \neq i)\right\}$, and $\tau_{x}(\theta \cdot F)$ is $\Lambda(\ell-1)$ measurable for $x \in \Lambda(\ell-n)$. In particular, these variables are independent under $\nu_{\rho}$. Since $\left\langle\eta_{z_{+}}-\eta_{z_{-}}\right\rangle_{\rho}=0$, we see that the last sum vanishes.

Summing up these calculations and bounds, we get (4.2).
For the CLT variance of $A_{\ell}$, it was shown in Theorem 5.1 of [14] that

$$
\begin{equation*}
\lim _{\ell, m \rightarrow \infty, m / \ell_{*}^{d} \rightarrow \rho} \ell_{*}^{-d} \Delta_{\ell, m, \zeta}\left(\theta \cdot A_{\ell}\right)=2\left(\theta \cdot \widetilde{c}^{-1}(\rho) \theta\right) \chi^{2}(\rho), \tag{4.8}
\end{equation*}
$$

uniformly in $\rho \in[0,1]$ and $\eta \in \mathcal{X}$, where $\zeta=\left.\eta\right|_{\Lambda(\ell)^{c} \text {. This is the key in the gradient }}$ replacement and shown based on a characterization of closed forms given in Corollary 4.1 of [14]. However, this is not sufficient for our purpose. Then, recently more detailed analysis has been developed by applying the method in the quantitative homogenization theory and, as a by-product, a decay rate in the limit (4.8) was obtained as in the following theorem; see (7.12) in 9].

Theorem 4.2. ([9]) For $m \in\left[0, \ell_{*}^{d}\right] \cap \mathbb{Z}, \zeta \in \mathcal{X}_{\Lambda(\ell)^{\text {c }}}$ and $\theta \in \mathbb{R}^{d}:|\theta|=1$, set

$$
Q_{\ell}^{(6)}(m, \zeta, \theta)=\ell_{*}^{-d} \Delta_{\ell, m, \zeta}\left(\theta \cdot A_{\ell}\right)-2\left(\theta \cdot \widehat{c}^{-1}\left(m / \ell_{*}^{d}\right) \theta\right) \chi^{2}\left(m / \ell_{*}^{d}\right)
$$

Then, there exist $C>0$ and $\alpha_{1}>0$ such that

$$
\left|Q_{\ell}^{(6)}(m, \zeta, \theta)\right| \leq C \ell^{-\alpha_{1}}
$$

uniformly in $m \in\left[0, \ell_{*}^{d}\right] \cap \mathbb{Z}, \zeta \in \mathcal{X}_{\Lambda(\ell)^{c}}$ and $\theta \in \mathbb{R}^{d}:|\theta|=1$.

The following corollary is immediate from Proposition 4.1 and Theorem 4.2, and gives a quantitative refinement of Corollary 5.1 of [14].

Corollary 4.3. Taking the supremum over all $m \in\left[0, \ell_{*}^{d}\right] \cap \mathbb{Z}, \zeta \in \mathcal{X}_{\Lambda(\ell)^{c}}$ and $\theta \in \mathbb{R}^{d}$ : $|\theta|=1$, set

$$
\begin{aligned}
& Q_{\ell}(F):=\sup \mid \ell_{*}^{-d} \Delta_{\ell, m, \zeta}\left(\theta \cdot\left\{D\left(m / \ell_{*}^{d}\right) A_{\ell}-\left(B_{\ell, \zeta}-H_{\ell, \zeta, F}\right)\right\}\right) \\
& \left.-\frac{1}{2}\left\{\theta \cdot \widehat{c}\left(m / \ell_{*}^{d} ; F\right) \theta-\theta \cdot \widehat{c}\left(m / \ell_{*}^{d}\right) \theta\right\} \right\rvert\,
\end{aligned}
$$

where $D(\rho)$ is the diffusion matrix defined in (1.7). Then, $Q_{\ell}(F)$ is estimated as

$$
Q_{\ell}(F) \leq C\left(1+r(F)^{2 d}\right)\left(1+\|F\|_{0, \infty}^{2}\right) \ell^{-1}+C \ell^{-\alpha_{1}}
$$

for some $C>0$ and $\alpha_{1}>0$.
Proof. Apply (4.1), (4.2) and Theorem 4.2) see the proof of Proposition 7.1 of 9 for more details.

## 5 Choice of $\beta, \ell, F, K$

### 5.1 Summary of the error estimates

Here we summarize the estimates for the error terms appearing in (3.64). Note that $\lambda(t, v)$ is now determined from the hydrodynamic equation (1.11) as in Lemma 3.13 and, in particular, the Schauder estimate (2.4) is applicable. We use the exponent

$$
\gamma:=\max \left\{3 \alpha_{0}, \alpha_{0}+1\right\}>0
$$

determined from $\alpha_{0}>0$ in (2.4). In the following, the constant $C=C_{T}>0$ changes from line to line and depends on $T$.

The term $Q_{N, \ell, \beta, K}^{\Omega_{1}}(\lambda, F)$ is the error for $\Omega_{1}$ with the non-gradient microscopic current function. It is given in (3.47) as

$$
\begin{equation*}
Q_{N, \ell, \beta, K}^{\Omega_{1}}(\lambda, F)=\frac{C}{\beta} K+\beta^{2} Q_{N, \ell}^{(1)}(\lambda, F)+\beta Q_{\ell}^{(2)}(\lambda, F)+Q_{N, \ell}^{(3)}(\lambda), \tag{5.1}
\end{equation*}
$$

where the first three terms are obtained in Theorem [3.5 and the last one in Lemma 3.7. Here, the term $Q_{N, \ell}^{(1)} \equiv Q_{N, \ell}^{(1)}(\lambda, F)$ is estimated in (3.30), and together with the Schauder estimate (2.4), we have

$$
\begin{equation*}
\left|Q_{N,,}^{(1)}\right| \leq C N^{-1} K^{\gamma} \ell^{2 d+4}\left(1+\|F\|_{0, \infty}^{3}\right) \tag{5.2}
\end{equation*}
$$

The term $Q_{\ell}^{(2)} \equiv Q_{\ell}^{(2)}(\lambda, F)$ is for the gradient replacement and is estimated in (3.31) together with (2.4) as

$$
\begin{equation*}
\left|Q_{\ell}^{(2)}\right| \leq C K^{\gamma} Q_{\ell}(F) \tag{5.3}
\end{equation*}
$$

and by Corollary 4.3,

$$
\begin{equation*}
Q_{\ell}(F) \leq C\left(1+r(F)^{2 d}\right)\left(1+\|F\|_{0, \infty}^{2}\right) \ell^{-1}+C \ell^{-\alpha_{1}} \tag{5.4}
\end{equation*}
$$

for some $\alpha_{1}>0$. The term $Q_{N, \ell}^{(3)} \equiv Q_{N, \ell}^{(3)}(\lambda)$ given in Lemma 3.7 is independent of $F$ and it is estimated from above as

$$
\begin{equation*}
Q_{N, \ell}^{(3)} \leq C K^{\gamma}\left(\ell^{-1}+N^{-1}\right)+C \beta K^{\gamma} \ell^{-1}+\frac{C}{\beta} K+C \beta^{2} K^{\gamma} N^{-1} \ell^{2 d-2} . \tag{5.5}
\end{equation*}
$$

The term $Q_{N, \ell, \delta_{*}}^{L D}(\lambda, F)$ appears in the large deviation estimate (see Theorems 3.11 and (3.9) after applying the entropy inequality and, by noting that we have $\left\|\partial_{v} G_{i}\right\|_{\infty} \leq C K^{\gamma}$, $\left\|\partial_{\rho} G_{i}\right\|_{\infty} \leq C K^{\gamma}$ for $i=1,2$ by Schauder estimates (2.3), (2.4) and the comparison theorem (Lemma 7.1) used for $\|\lambda\|_{\infty}$, it is estimated as

$$
\begin{equation*}
\left|Q_{N, \ell, \delta_{*}}^{L D}(\lambda, F)\right| \leq C N^{-1} K^{\gamma}\left(\ell+\|F\|_{\infty}\right)+C \ell^{-d}\left(\log \ell+K^{\gamma}\right) . \tag{5.6}
\end{equation*}
$$

The term $Q_{N}^{E n}(\lambda, F)$ is the error in the entropy calculation and is estimated as in (3.3). Indeed, together with the Schauder estimate (2.4) and the comparison theorem (Lemma 7.1), we have

$$
\begin{equation*}
\left|Q_{N}^{E n}(\lambda, F)\right| \leq C N^{-1} K^{\gamma}\left(1+\|F\|_{2, \infty}\right)^{3}, \tag{5.7}
\end{equation*}
$$

if the condition (3.4), in particular,

$$
\begin{equation*}
N^{-1} K^{\gamma}\|F\|_{0, \infty} \leq 1 \tag{5.8}
\end{equation*}
$$

is satisfied.
The term $Q_{N, \ell}^{\Omega_{2}}(\lambda, F)$ estimated in (3.49) is the error for the one-block estimate (3.25) applied for the gradient term $\Omega_{2}$, adding the discretization error of (3.51). Applying the Schauder estimate (2.4), it is bounded as

$$
\begin{align*}
\left|Q_{N, \ell}^{\Omega_{2}}(\lambda, F)\right| \leq C K^{\gamma} & \left(N^{-1} K^{1 / 2} \ell^{(d+2) / 2}+\ell^{-d}\left(1+r(F)^{d}\right)\right)  \tag{5.9}\\
& \times\left(1+\|F\|_{0, \infty}^{2}+\|F\|_{1, \infty}\right)+C K^{\gamma} N^{-1} .
\end{align*}
$$

### 5.2 Choice of $\beta, \ell, F, K$

By Lemma 4.4 and Proposition 6.9 of [9] (see also Theorem 1.2 and Section 7 of [9), one can find a sequence of local functions $\Phi_{n}=\Phi_{n}(\eta) \in\left(\mathcal{F}_{0}\right)^{d}$ on $\mathcal{X}$ such that

$$
\begin{equation*}
r\left(\Phi_{n}\right) \leq n, \quad \sup _{\rho \in[0,1]}\left\|R\left(\rho ; \Phi_{n}\right)\right\| \leq C_{2} n^{-\alpha_{2}}, \quad\left\|\Phi_{n}\right\|_{\infty} \leq C_{2} n^{2} \log n, \tag{5.10}
\end{equation*}
$$

for some $C_{2}>0$ and $\alpha_{2}>0$. We will choose $n=n(N), \ell=\ell(N), K=K(N)$ and $\beta=\beta(n)$, from which we can determine $\beta(N):=\beta(n(N))$ and $F_{N}:=\Phi_{n(N)}$ (i.e. $\Phi_{n}$ with $n=n(N)$ ), respectively. In fact, we will choose $1 \leq n=N^{a_{1}} \ll \ell=N^{a_{2}} \ll N$ with exponents

$$
\begin{equation*}
0<a_{1}<a_{2}:=1 /(2 d+5)<1 . \tag{5.11}
\end{equation*}
$$

In particular, the radius $r\left(\Phi_{n}\right)$ of the support of $\Phi_{n}$ is much smaller than $\ell$ so that the arguments in Section 4 work smoothly for $F=F_{N}$; note that $n$ in $H_{\ell}(\eta)$ in (3.37) is taken as $n=r(F)+1$ so that it is $n+1$ with $n$ given here.

For $K=K(N) \geq 1$, we assume

$$
\begin{equation*}
1 \leq K \leq \bar{K}_{\delta}(N):=\delta \log N \tag{5.12}
\end{equation*}
$$

and will make $\delta>0$ sufficiently small. In particular, by (5.11) and (5.12), the condition (3.24) holds (note that $\delta>0$ in (3.24) is different from that in (5.12)). Moreover, also noting (5.10), the condition (5.8) holds. We will take $\beta=n^{\alpha_{2} / 2}$.

In (3.64), setting $c_{*}:=T / \delta_{*}$ with $\delta_{*}>0$ chosen in Lemma 3.13, the factor $e^{K t / \delta_{*}}$ is bounded by $e^{c_{*} K} \leq N^{c_{*} \delta}$ for $t \in[0, T]$. We also bound $K, K^{\gamma} \leq C N^{c_{*} \delta}$ for simplicity. Below we give a bound for each of the nine terms in (3.64) (recall that $Q_{N, \ell, \beta, K}^{\Omega_{1}}\left(\lambda, F_{N}\right)$ consists of four terms as in (3.47) or equivalently (5.1)) first choosing $a_{1}>0$ small enough and then $c_{*} \delta=T \delta / \delta_{*}$, so $\mathfrak{c}=T \delta$ in Proposition 2.1 and Theorem 1.1, further small. The constants $\bar{C}$ and $\kappa$ below may change from line to line but they can always be taken as $\bar{C}=\bar{C}_{T}>0$ and $\kappa>0(\bar{C}$ large enough depending on $T$, while $\kappa$ small enough depending on $\mathfrak{c}$ but independently of $T$ and $\delta$ ).

1. The term $\beta^{2} Q_{N, \ell}^{(1)}(\lambda, F) \cdot e^{c_{*} K}$ in (5.1) with $e^{c_{*} K}$ is bounded, from (5.2) and (5.10), by

$$
C n^{\alpha_{2}} N^{-1} \ell^{2 d+4} n^{3 d+7} N^{2 c_{*} \delta} \leq \bar{C} N^{-\kappa}
$$

Note that $\ell^{2 d+4}=N^{(2 d+4) /(2 d+5)}$ by (5.11).
2. The term $\beta Q_{\ell}^{(2)}(\lambda, F) \cdot e^{c_{*} K}$ in (5.1) is bounded, from (5.3), (5.4) and (5.10), by

$$
C n^{\alpha_{2} / 2}\left(n^{4 d+5} \ell^{-1}+\ell^{-\alpha_{1}}\right) N^{2 c_{*} \delta} \leq \bar{C} N^{-\kappa}
$$

3. The upper bound of $Q_{N, \ell}^{(3)}(\lambda) \cdot e^{c_{*} K}$ in (5.1) is given, from (5.5), by

$$
C\left\{\ell^{-1}+N^{-1}+n^{\alpha_{2} / 2} \ell^{-1}+n^{-\alpha_{2} / 2}+n^{\alpha_{2}} N^{-1} \ell^{2 d-2}\right\} N^{2 c_{*} \delta} \leq \bar{C} N^{-\kappa}
$$

4. The term $\left|Q_{N, \ell, \delta_{*}}^{L D}(\lambda, F)\right| \cdot e^{c_{*} K}$ is bounded, from (5.6) and (5.10), by

$$
C\left\{N^{-1}\left(\ell+n^{3}\right)+\ell^{-d} \log \ell\right\} N^{2 c_{*} \delta} \leq \bar{C} N^{-\kappa}
$$

5. Noting that (5.8) is satisfied, the term $Q_{N}^{E n}(\lambda, F) \cdot e^{c_{*} K}$ is bounded, from (5.7) and (5.10), by

$$
C N^{-1} n^{3 d+13} N^{2 c_{*} \delta} \leq \bar{C} N^{-\kappa}
$$

6. The term $\left|Q_{N, \ell}^{\Omega_{2}}(\lambda, F)\right| \cdot e^{c_{*} K}$ is bounded, from (5.9) and (5.10), by

$$
C\left(N^{-1} \ell^{(d+2) / 2}+\ell^{-d} n^{d}\right) n^{2 d+5} N^{3 c_{*} \delta}+C N^{2 c_{*} \delta} N^{-1} \leq \bar{C} N^{-\kappa}
$$

7. The term $(\beta+1) K^{\gamma} \sup _{\rho \in[0,1]}\|R(\rho ; F)\| \cdot e^{c_{*} K}$ is bounded, from (5.10), by

$$
C n^{\alpha_{2} / 2} N^{2 c_{*} \delta} n^{-\alpha_{2}} \leq \bar{C} N^{-\kappa},
$$

by choosing $\delta>0$ small, once $a_{1}>0$ is determined in the above procedure.
8. The term $\frac{C}{\beta} K \cdot e^{c_{*} K}$ in (5.1) with $e^{c_{*} K}$ is bounded by

$$
C n^{-\alpha_{2} / 2} N^{2 c_{*} \delta} \leq \bar{C} N^{-\kappa},
$$

by choosing $\delta>0$ small enough.
9. Finally, by the assumption $h_{N}(0) \leq C_{1} N^{-\kappa_{1}}, C_{1}, \kappa_{1}>0$ of Proposition 2.1, we have

$$
h_{N}(0) e^{c_{*} K} \leq \bar{C} N^{-\kappa} .
$$

Nine terms in (3.64) are all bounded by $\bar{C} N^{-\kappa}$ and therefore one can conclude the proof of Proposition 2.1 as already stated at the end of Section 3.7.

## 6 Schauder estimates

Here we give the proof of the Schauder estimates (2.3) for the solution $\rho=\rho(t, v) \equiv \rho_{K}(t, v)$ of (1.11). We apply the results given in 21 for linear second order parabolic partial differential equations (PDEs). See also [20], but an explicit dependence of the constants in the estimates on several data of the equation is not clearly indicated as in (6.6), (6.7) below.

Before showing the Schauder estimates, we briefly note that the equation (1.11) has a unique classical solution $\rho(t, v) \in C^{1,3}\left([0, \infty) \times \mathbb{T}^{d}\right)$ under the condition $\rho_{0} \in C^{4}\left(\mathbb{T}^{d}\right)$ for its initial value; recall (1.12) in which $\rho_{0} \in C^{5}\left(\mathbb{T}^{d}\right)$ is assumed. In fact, noting that (1.11) is a quasi-linear equation in divergence form (0.1) in Chapter V of [20], p.417, by Theorem 6.1 of [20], p. 452, we see that it has a unique classical solution $\rho(t, v) \in C^{1,2}\left([0, \infty) \times \mathbb{T}^{d}\right)$ if $\rho_{0} \in C^{3}\left(\mathbb{T}^{d}\right)$. Note that the consistency condition (6.3) assumed in Theorem 6.1 is unnecessary in our setting, since $\mathbb{T}^{d}$ has no boundary. To obtain $C^{1,3}$-property, we consider the equation for the derivative $\rho_{(k)}:=\partial_{v_{k}} \rho(t, v)$ for each fixed $k: 1 \leq k \leq d$. By a simple calculation, we see that $\rho_{(k)}$ satisfies the equation (0.1) of [20] with

$$
\begin{aligned}
& a_{i}(v, t, p)=\sum_{j=1}^{d} D_{i j}(\rho(t, v)) p_{j}+\sum_{j=1}^{d} D_{i j}^{\prime}(\rho(t, v)) \partial_{v_{k}} \rho(t, v) \partial_{v_{j}} \rho(t, v), \\
& a(v, t)=-f^{\prime}(\rho(t, v)) \partial_{v_{k}} \rho(t, v),
\end{aligned}
$$

where we regard that $\rho(t, v), \partial_{v_{k}} \rho(t, v)$ and $\partial_{v_{i}} \rho(t, v)$ are all given. Then, applying Theorem 6.1 of [20] again, we see that $\rho_{(k)} \in C^{1,2}\left([0, \infty) \times \mathbb{T}^{d}\right)$ if $\partial_{v_{k}} \rho_{0} \in C^{3}\left(\mathbb{T}^{d}\right)$ for each $k$. This shows $\rho(t, v) \in C^{1,3}\left([0, \infty) \times \mathbb{T}^{d}\right)$ under the condition $\rho_{0} \in C^{4}\left(\mathbb{T}^{d}\right)$.

Now we show the Schauder estimates. To apply the results of [21], the first step is to show the Hölder continuity of the solution of the nonlinear PDE (1.11).

For this purpose, first in (1.11) dropping the term $K f(\rho(t, v))$ and replacing $D(\rho(t, v))$ by $D(t, v)=\left\{D_{i j}(t, v)\right\}_{1 \leq i, j \leq d}$ which is symmetric matrix-valued Borel measurable function on $[0, T] \times \mathbb{T}^{d}$ satisfying a bound similar to (1.9): $c_{*}|\theta|^{2} \leq(\theta, D(t, v) \theta) \leq c^{*}|\theta|^{2}$ for $\theta \in \mathbb{R}^{d}$ with $c_{*}, c^{*}>0$, we consider a solution $u^{(0)}=u^{(0)}(t, v)$ of the linear parabolic PDE

$$
\begin{equation*}
\partial_{t} u^{(0)}=\sum_{i, j=1}^{d} \partial_{v_{i}}\left\{D_{i j}(t, v) \partial_{v_{j}} u^{(0)}\right\}, \quad t \geq 0, v \in \mathbb{T}^{d} \tag{6.1}
\end{equation*}
$$

with initial value $u_{0}$. Let $p(t, v ; s, \xi), v, \xi \in \mathbb{T}^{d}, 0 \leq s<t \leq T$ be the associated fundamental solution. Then, we have the following Nash Hölder estimates; cf. [27, [24] and related estimates can also be found in [20].

Lemma 6.1. There exist $\sigma \in(0,1]$ and $C>0$ such that

$$
\begin{equation*}
\left|u^{(0)}\left(t_{1}, v_{1}\right)-u^{(0)}\left(t_{2}, v_{2}\right)\right| \leq C\left\|u_{0}\right\|_{\infty}\left(\frac{\left|t_{1}-t_{2}\right|^{1 / 2} \vee\left|v_{1}-v_{2}\right|}{\left(t_{1} \wedge t_{2}\right)^{1 / 2}}\right)^{\sigma} \tag{6.2}
\end{equation*}
$$

for $t_{1}, t_{2} \in(0, T], v_{1}, v_{2} \in \mathbb{T}^{d}$ and

$$
\begin{equation*}
\left|p\left(t_{1}, v_{1} ; 0, \xi_{1}\right)-p\left(t_{2}, v_{2} ; 0, \xi_{2}\right)\right| \leq \frac{C}{\left(t_{1} \wedge t_{2}\right)^{d / 2}}\left(\frac{\left|t_{1}-t_{2}\right|^{1 / 2} \vee\left|v_{1}-v_{2}\right| \vee\left|\xi_{1}-\xi_{2}\right|}{\left(t_{1} \wedge t_{2}\right)^{1 / 2}}\right)^{\sigma} \tag{6.3}
\end{equation*}
$$

for $t_{1}, t_{2} \in(0, T], v_{1}, v_{2}, \xi_{1}, \xi_{2} \in \mathbb{T}^{d}$.
Proof. To show (6.2), we separate into two cases: $\left(t_{1} \vee t_{2}\right) \geq 2\left(t_{1} \wedge t_{2}\right)$ and $\left(t_{1} \vee t_{2}\right)<$ $2\left(t_{1} \wedge t_{2}\right)$. In the case $\left(t_{1} \vee t_{2}\right) \geq 2\left(t_{1} \wedge t_{2}\right)$, since $\left|t_{1}-t_{2}\right|=\left(t_{1} \vee t_{2}\right)-\left(t_{1} \wedge t_{2}\right) \geq\left(t_{1} \wedge t_{2}\right)$, (6.2) is obvious with $C=2$, noting $\left\|u^{(0)}(t)\right\|_{\infty} \leq\left\|u_{0}\right\|_{\infty}$ by the maximum principle; see Lemma 7.1 below with $f \equiv 0$.

In the other case $\left(t_{1} \vee t_{2}\right)<2\left(t_{1} \wedge t_{2}\right)$, we take $t_{0}=2\left(t_{1} \wedge t_{2}\right), R=\sqrt{2}\left(t_{1} \wedge t_{2}\right)^{1 / 2}$, $\delta=\sqrt{2 / 3}$ and $x_{0}=v_{1}$ in Theorem 4.1 of [24] (or Theorem II.1.8 of [27], although it is stated only for the time-homogeneous case). Note that $t_{0}-R^{2}=0$ and $t_{1}, t_{2} \in$ $\left(t_{0}-(\delta R)^{2}, t_{0}\right)=\left(2 / 3\left(t_{1} \wedge t_{2}\right), 2\left(t_{1} \wedge t_{2}\right)\right)$. Then, by Theorem 4.1 of [24], (6.2) holds if $\left|v_{1}-v_{2}\right| \leq \sqrt{4 / 3}\left(t_{1} \wedge t_{2}\right)^{1 / 2}$. If $\left|v_{1}-v_{2}\right| \geq \sqrt{4 / 3}\left(t_{1} \wedge t_{2}\right)^{1 / 2}$, (6.2) is obvious with $C=2$.

To show (6.3), taking $\delta=\left(t_{1} \wedge t_{2}\right)^{1 / 2}$ in Corollary 4.2 of [24] (or Corollary II.1.9 of [27]), this holds if $\left|v_{1}-v_{2}\right| \vee\left|\xi_{1}-\xi_{2}\right| \leq\left(t_{1} \wedge t_{2}\right)^{1 / 2}$. Conversely, if $\left|v_{1}-v_{2}\right| \vee\left|\xi_{1}-\xi_{2}\right| \geq\left(t_{1} \wedge t_{2}\right)^{1 / 2}$, by Aronson's Gaussian upper bound (see Theorem 1.2 of [24]), we have

$$
\begin{aligned}
\left|p\left(t_{1}, v_{1} ; 0, \xi_{1}\right)-p\left(t_{2}, v_{2} ; 0, \xi_{2}\right)\right| & \leq p\left(t_{1}, v_{1} ; 0, \xi_{1}\right)+p\left(t_{2}, v_{2} ; 0, \xi_{2}\right) \\
& \leq C t_{1}^{-d / 2}+C t_{2}^{-d / 2} \leq 2 C\left(t_{1} \wedge t_{2}\right)^{-d / 2}
\end{aligned}
$$

and this is bounded by the right-hand side of (6.3) (with $C$ replaced by $2 C$ ).
This lemma is used to show the Hölder continuity of the solution $\rho(t, v) \equiv \rho_{K}(t, v), K \geq$ 1 of (1.11) with $\rho(0)=\rho_{0}$. The regularity of $\rho_{0}$ allows to remove the singularity of $\rho(t, v)$ near $t=0$.

Lemma 6.2. Assume the condition (1.12) for $\rho_{0}$. Then, we have

$$
\begin{equation*}
\left|\rho\left(t_{1}, v_{1}\right)-\rho\left(t_{2}, v_{2}\right)\right| \leq C K\left(\left|t_{1}-t_{2}\right|^{\sigma / 2}+\left|v_{1}-v_{2}\right|^{\sigma}\right), \quad t_{1}, t_{2} \in[0, T], v_{1}, v_{2} \in \mathbb{T}^{d} \tag{6.4}
\end{equation*}
$$

for some $\sigma \in(0,1]$. Since $D(\rho)=\left\{D_{i j}(\rho)\right\}_{1 \leq i, j \leq d} \in C^{\infty}([0,1])$, we have a similar Hölder estimate for $D_{i j}(\rho(t, v))$.

Proof. The proof is similar to that of Corollary 2.6 of [13] (in the discrete setting). First, let $D(t, v)$ be as above and let $g(t, v)$ be a bounded Borel measurable function. We consider the linear PDE

$$
\partial_{t} u=\sum_{i, j=1}^{d} \partial_{v_{i}}\left\{D_{i j}(t, v) \partial_{v_{j}} u\right\}+g(t, v), \quad t \geq 0, v \in \mathbb{T}^{d},
$$

with $u(0)=u_{0}$. Then, by Duhamel's formula, we have

$$
u(t, v)=u^{(0)}(t, v)+\int_{0}^{t} d s \int_{\mathbb{T}^{d}} g(s, \xi) p(t, v ; s, \xi) d \xi,
$$

where $u^{(0)}(t, v)$ is the solution of (6.1). Then, by Lemma 6.1 (actually only by (6.2)), similar to the proof of Theorem 2.2 of [13], we get

$$
\begin{equation*}
\left|u\left(t_{1}, v_{1}\right)-u\left(t_{2}, v_{2}\right)\right| \leq C\left(\left\|u_{0}\right\|_{\infty}+\|g\|_{\infty}\right)\left(\frac{\left|t_{1}-t_{2}\right|^{1 / 2}+\left|v_{1}-v_{2}\right|}{\left(t_{1} \wedge t_{2}\right)^{1 / 2}}\right)^{\sigma}, \tag{6.5}
\end{equation*}
$$

for $t_{1}, t_{2} \in(0, T], v_{1}, v_{2} \in \mathbb{T}^{d}$.
To improve the regularity near $t=0$, we apply a trick similar to the one used in the proof of Theorem 2.5 of [13]. We supplementarily consider the heat equation on $\mathbb{T}^{d}$

$$
\partial_{s} U=\Delta U, \quad s \in(0,1]
$$

with $U(0)=\rho_{0}$, and set $\hat{U}(t):=U(1-t)$ and $\hat{h}(t, v):=-\Delta \hat{U}(t, v)$ for $t \in[0,1)$. Then, $\hat{U}(t, v)$ satisfies the equation

$$
\partial_{t} \hat{U}=-\Delta \hat{U}=\Delta \hat{U}+2 \hat{h} .
$$

Since $h(t):=\hat{h}(1-t)=-\Delta U(t)$ satisfies $\partial_{t} h(t)=\Delta h(t)$ with $h(0)=-\Delta U(0)=-\Delta \rho_{0}$, we see by the maximum principle that $\|h(t)\|_{\infty} \leq\left\|\Delta \rho_{0}\right\|_{\infty}<\infty$ by (1.12).

To apply (6.5) for our equation (1.11), define $\hat{\rho}(t, v),\left\{\hat{D}_{i j}(t, v)\right\}$ and $\hat{g}(t, v)$, respectively, by

$$
\begin{aligned}
& \hat{\rho}(t, v)=\left\{\begin{aligned}
\rho(t-1, v), & t \in[1, T+1], \\
\hat{U}(t, v), & t \in[0,1) .
\end{aligned}\right. \\
& \hat{D}_{i j}(t, v)=\left\{\begin{aligned}
D_{i j}(\rho(t-1, v)), & t \in[1, T+1], \\
\delta_{i j}, & t \in[0,1),
\end{aligned}\right. \\
& \hat{g}(t, v)=\left\{\begin{aligned}
K f(\rho(t-1, v)), & t \in[1, T+1], \\
2 \hat{h}(t, v), & t \in[0,1),
\end{aligned}\right.
\end{aligned}
$$

where $\rho(t, v) \equiv \rho_{K}(t, v)$ is the solution of (1.11) with initial value $\rho_{0}$. Then, these functions satisfy

$$
\partial_{t} \hat{\rho}=\sum_{i, j=1}^{d} \partial_{v_{i}}\left(\hat{D}_{i j}(t, v) \partial_{v_{i}} \hat{\rho}\right)+\hat{g}(t, v),
$$

with $\hat{\rho}(0, v)=U(1)$. Note that $\|U(1)\|_{\infty} \leq\left\|\rho_{0}\right\|_{\infty}$. So, noting that $\|\hat{g}\|_{\infty} \leq K\|f\|_{\infty}+$ $2\left\|\Delta \rho_{0}\right\|_{\infty}$ and $\left\{\hat{D}_{i j}\right\}$ satisfies the uniform positive-definiteness and boundedness conditions, from (6.5) with $T$ replaced by $T+1$, we have

$$
\left|\hat{\rho}\left(t_{1}, v_{1}\right)-\hat{\rho}\left(t_{2}, v_{2}\right)\right| \leq C\left(\left\|\rho_{0}\right\|_{\infty}+\|\hat{g}\|_{\infty}\right)\left(\frac{\left|t_{1}-t_{2}\right|^{1 / 2}+\left|v_{1}-v_{2}\right|}{\left(t_{1} \wedge t_{2}\right)^{1 / 2}}\right)^{\sigma}
$$

for $t_{1}, t_{2} \in(0, T+1], v_{1}, v_{2} \in \mathbb{T}^{d}$. The desired bound (6.4) is obtained by restricting the above estimate to $[1, T+1]$ and shifting it by 1 in time.

Now we apply Theorem 4.8 of [21], in particular the detailed estimate given on p. 59 for a solution $u$ of the linear equation (4.22) of [21] cited below. Before explaining it, let us first recall several Hölder norms for functions on $\Omega=[0, T] \times \mathbb{T}^{d}$ from pp.46-47 of [21]. The sup-norm on $\Omega$ is denoted by $\|\cdot\|_{\infty}=|\cdot|_{0} \equiv|\cdot|_{0}^{(0)}$ and let $\alpha \in(0,1]$. The (semi) norms $[u]_{\alpha}^{(b)}, b=0,1,|u|_{\alpha}^{(1)}$ and $|u|_{1+\alpha}^{*} \equiv|u|_{1+\alpha}^{(0)}$ are defined for functions $u$ on $\Omega$ which may have a singularity like $t^{-1 / 2}$ or others near $t=0$, respectively, by

$$
\begin{aligned}
& {[u]_{\alpha}^{(b)}=} \sup _{X \neq Y}(t \wedge s)^{(\alpha+b) / 2} \frac{|u(X)-u(Y)|}{|X-Y|^{\alpha}}, \quad b=0,1, \\
&|u|_{\alpha}^{(1)}=|u|_{0}^{(1)}+[u]_{\alpha}^{(1)}, \quad|u|_{0}^{(1)}=\sup _{\Omega} t^{1 / 2}|u(X)|, \\
&|u|_{1+\alpha}^{(0)}:=\|u\|_{\infty}+\left|\partial_{v} u\right|_{0}^{(1)}+[u]_{1+\alpha}^{(0)}+\langle u\rangle_{1+\alpha}^{(0)} \\
& \equiv\|u\|_{\infty}+\sup _{\Omega} t^{1 / 2}\left|\partial_{v} u(X)\right|+\sup _{X \neq Y}(t \wedge s)^{(1+\alpha) / 2} \frac{\left|\partial_{v} u(X)-\partial_{v} u(Y)\right|}{|X-Y|^{\alpha}} \\
& \quad+\sup _{X \neq Y, x=y}(t \wedge s)^{(1+\alpha) / 2} \frac{|u(X)-u(Y)|}{|X-Y|^{1+\alpha}},
\end{aligned}
$$

where $X=(t, v), Y=\left(s, v^{\prime}\right) \in \Omega$ and $|X-Y|=\max \left\{|x-y|,|t-s|^{1 / 2}\right\}$. Note that $d(X, Y)=\min \{d(X), d(Y)\}=\min \left\{t^{1 / 2}, s^{1 / 2}\right\}=(t \wedge s)^{1 / 2}$ and $\langle u\rangle_{\alpha}^{(1)}=0$ in the norm $|u|_{\alpha}^{(1)}$ on p. 47 of [21]. The norm $|u|_{1+\alpha}$ for functions $u$ without singularity near $t=0$ is defined on p. 46 of 21] as

$$
|u|_{1+\alpha}:=\|u\|_{\infty}+\left\|\partial_{v} u\right\|_{\infty}+\sup _{X \neq Y} \frac{\left|\partial_{v} u(X)-\partial_{v} u(Y)\right|}{|X-Y|^{\alpha}}+\sup _{X \neq Y, x=y} \frac{|u(X)-u(Y)|}{|X-Y|^{1+\alpha}} .
$$

The detailed estimate mentioned above clarifies the dependence of the constants in the estimate on various data; see (6.6) below. The equation (4.22) of [21] is defined as follows on $\Omega$ and written by dropping the sums in $i, j$ as

$$
\begin{equation*}
-\partial_{t} u+\partial_{v_{i}}\left(a^{i j} \partial_{v_{j}} u+b^{i} \partial_{v_{i}} u\right)+c^{i} \partial_{v_{i}} u+c^{0} u=\partial_{v_{i}} f^{i}+g, \tag{4.22}
\end{equation*}
$$

where $a^{i j}, b^{i}, f^{i}$ are $\alpha$-Hölder continuous and $c^{i}, c^{0}, g$ are bounded measurable functions on $\Omega$ that satisfy

$$
\begin{align*}
& \lambda|\xi|^{2} \leq a^{i j} \xi_{i} \xi_{j} \leq \Lambda|\xi|^{2}, \quad\left[a^{i j}\right]_{\alpha}^{(0)} \leq A,  \tag{4.20a}\\
& \left|b^{i}\right|_{\alpha}^{(1)} \leq B,  \tag{4.20b}\\
& \left\|c^{i}\right\|_{\infty} \leq c_{1}, \quad\left\|c^{0}\right\|_{\infty} \leq c_{2},  \tag{4.20c}\\
& \left|f^{i}\right|_{\alpha}^{(1)} \leq F, \quad\|g\|_{\infty} \leq G, \tag{4.21}
\end{align*}
$$

for some positive constants $\lambda, \Lambda, A, B, c_{1}, c_{2}, F$ and $G$. Then, we have

$$
\begin{equation*}
|u|_{1+\alpha}^{*}\left(\equiv|u|_{1+\alpha}^{(0)}\right) \leq C(d, \alpha, \lambda, \Lambda)\left(M\|u\|_{\infty}+F+G\right) \tag{6.6}
\end{equation*}
$$

with

$$
\begin{equation*}
M=\left[1+A+c_{1}\right]^{(1+\alpha) / \alpha}+\sum_{i}\left(\left|b^{i}\right|_{0}^{(1)}\right)^{1+\alpha}+c_{2}+\sum_{i}\left[b^{i}\right]_{\alpha}^{(1)} . \tag{6.7}
\end{equation*}
$$

In our applications, we will take $b^{i}=c^{i}=0$. Note that the above conditions (4.20c) and (4.21) are simplifications of those in [21] by noting that $\|\cdot\|_{p, \delta}^{(b)} \leq C\|\cdot\|_{\infty}$ for $b=1,2$, but these will suffice for our purpose.

First, we consider (1.11) to be a linear equation (4.22) for $u=\rho$ with $a^{i j}=D_{i j}(\rho(t, v))$, $g=-K f(\rho(t, v))$ where $\rho(t, v)$ is already given and $b^{i}=c^{i}=c^{0}=f^{i}=0$. Then, since (6.4) implies $\left[a^{i j}\right]_{\sigma}^{(0)} \leq C K$ (note that $(t \wedge s)^{\alpha / 2} \leq T^{\alpha / 2}$ is bounded), one can take $\alpha=\sigma, A=C K$ in the estimate (4.20a) and $G=C K$ in (4.21). So, noting $M=[1+A]^{(1+\sigma) / \sigma} \leq C K^{(1+\sigma) / \sigma}$ and $\|u\|_{\infty} \leq 1$, we obtain by (6.6) the estimate:

$$
\begin{equation*}
|\rho|_{1+\sigma}^{*} \leq C K^{(1+\sigma) / \sigma}, \tag{6.8}
\end{equation*}
$$

for the solution $\rho$ of (1.11). Here and in the following, we use the comparison theorem for (1.11), that is, under our assumption (1.12) for the initial value $\rho_{0}$, we have $0<c \leq$ $\rho(t, v) \leq 1-c<1$ for some $c \in(0,1 / 2)$; see Lemma 7.1 below.

Considering the extended system in time similar to the proof of Lemma 6.2 (see also Theorem 4.2 of [13]), the regularity of the initial value $\rho_{0}(v)$ improves the estimate (6.8) into that without singularity near $t=0$. In fact, we have the following lemma.

Lemma 6.3. For the norm without singularity, we have

$$
\begin{equation*}
|\rho|_{1+\sigma} \leq C K^{(1+\sigma) / \sigma} . \tag{6.9}
\end{equation*}
$$

Proof. Since we need to extend $a^{i j}$ to $\hat{a}^{i j}$ while preserving its $\sigma$-Hölder property, we modify the choice of $\hat{D}_{i j}$ in the proof of Lemma 6.2. We take $\hat{b}^{i}=\hat{c}^{i}=\hat{c}^{0}=\hat{f}^{i}=0$ and define $\hat{u}(t, v),\left\{\hat{a}^{i j}(t, v)\right\}$ and $\hat{g}(t, v)$, respectively, by

$$
\begin{align*}
& \hat{u}(t, v)=\left\{\begin{aligned}
\rho(t-1, v), & t \in[1, T+1], \\
\hat{U}(t, v), & t \in[0,1) .
\end{aligned}\right. \\
& \hat{a}^{i j}(t, v)=\left\{\begin{aligned}
D_{i j}(\rho(t-1, v)), & t \in[1, T+1], \\
D_{i j}\left(\rho_{0}(v)\right), & t \in[0,1),
\end{aligned}\right. \tag{6.10}
\end{align*}
$$

$$
\hat{g}(t, v)=\left\{\begin{aligned}
-K f(\rho(t-1, v)), & t \in[1, T+1], \\
-2 \hat{h}(t, v), & t \in[0,1),
\end{aligned}\right.
$$

where $\hat{U}(t):=U(1-t)$ is defined from the solution $U(s), s \in[0,1]$ of the equation

$$
\partial_{s} U=L_{\rho_{0}} U \equiv \partial_{v_{i}}\left(D_{i j}\left(\rho_{0}(v)\right) \partial_{v_{j}} U\right), \quad s \in(0,1],
$$

with initial value $U(0)=\rho_{0}$, and $\hat{h}(t, v):=-L_{\rho_{0}} \hat{U}(t, v), t \in[0,1]$. Then, $\hat{U}(t)$ satisfies the equation

$$
\partial_{t} \hat{U}=-L_{\rho_{0}} \hat{U}=L_{\rho_{0}} \hat{U}+2 \hat{h} .
$$

For $\hat{g}$, the measurability is sufficient.
Note that $h(t):=\hat{h}(1-t)=-L_{\rho_{0}} U(t)$ satisfies the equation $\partial_{t} h(t)=L_{\rho_{0}} h(t)$ and $h(0)=\hat{h}(1)=-L_{\rho_{0}} U(0)=-L_{\rho_{0}} \rho_{0}$. Thus, according to the maximum principle noting

$$
L_{\rho_{0}} u=D_{i j}\left(\rho_{0}\right) \partial_{v_{i}} \partial_{v_{j}} u+D_{i j}^{\prime}\left(\rho_{0}\right) \partial_{v_{i}} \rho_{0} \cdot \partial_{v_{j}} u
$$

we see

$$
\|h(t)\|_{\infty} \leq\left\|L_{\rho_{0}} \rho_{0}\right\|_{\infty} \leq C\left(\left\|\partial^{2} \rho_{0}\right\|_{\infty}+\left\|\partial \rho_{0}\right\|_{\infty}^{2}\right)<\infty
$$

since $\rho_{0} \in C^{2}\left(\mathbb{T}^{d}\right)$ by our condition (1.12). So we have $\|\hat{g}\|_{\infty} \leq C K$.
Since $\left[\hat{a}^{i j}\right]_{\sigma}^{(0)} \leq C K$, (6.8) holds for the extended solution $\hat{u}(t, v)$ on $[0, T+1]$. Restricting this estimate to $[1, T+1]$, (6.9) follows.

Second, we take the derivative of (1.11) in $v_{k}$ and obtain by dropping the sum in $i, j$

$$
\begin{align*}
\partial_{t} \rho_{v_{k}} & =\partial_{v_{i}}\left(\partial_{v_{k}}\left\{D_{i j}(\rho) \partial_{v_{j}} \rho\right\}\right)+K f^{\prime}(\rho) \rho_{v_{k}}  \tag{6.11}\\
& =\partial_{v_{i}}\left\{D_{i j}(\rho) \partial_{v_{j}} \rho_{v_{k}}\right\}-\partial_{v_{i}} f^{i,(1)}(\rho)+K f^{\prime}(\rho) \rho_{v_{k}}
\end{align*}
$$

where

$$
f^{i,(1)}(\rho):=-\sum_{j=1}^{d} D_{i j}^{\prime}(\rho) \rho_{v_{k}} \rho_{v_{j}} .
$$

We consider this equation to be a linear equation (4.22) for $u=\rho_{v_{k}}$ with $a^{i j}=D_{i j}(\rho)$, $b^{i}=c^{i}=0, f^{i}=f^{i,(1)}(\rho)$ (here both $\rho_{v_{k}}=\rho_{v_{k}}(t, v)$ and $\rho_{v_{j}}=\rho_{v_{j}}(t, v)$ are considered already given) and $c^{0}=K f^{\prime}(\rho)$. We may add a bounded function $g$ (actually, $\hat{g}$ ) to apply for the proof of the next Lemma 6.4. Then, one can take $A=C K, F=C K\left(K^{(1+\sigma) / \sigma}\right)^{2}$ by using (6.4) (for Hölder estimate for $\left.D^{\prime}(\rho)\right)$ and (6.9) (noting that we can drop $t^{1 / 2}$ and $(t \wedge s)^{(1+\alpha) / 2}$ in the norm $\left|f^{i}\right|_{\alpha}^{(1)}$, since these are bounded) and $c_{2}=C K$. Thus, by (6.6) with $G$ for $g$ (for later use, currently $g=0$ ), we obtain the estimate:

$$
\begin{equation*}
|u|_{1+\sigma}^{*} \leq C\left(M\|u\|_{\infty}+K^{2(1+\sigma) / \sigma+1}+G\right) \tag{6.12}
\end{equation*}
$$

with $M=[1+A]^{(1+\sigma) / \sigma}+K$. Therefore, noting $\|u\|_{\infty}=\left\|\rho_{v_{k}}\right\|_{\infty} \leq C K^{(1+\sigma) / \sigma}$ by (6.9) and $G=0$, we have

$$
\begin{equation*}
|\partial \rho|_{1+\sigma}^{*} \leq C K^{2(1+\sigma) / \sigma+1} . \tag{6.13}
\end{equation*}
$$

We can apply a similar argument to the proof of Lemma 6.3 to remove the singularity near $t=0$.

Lemma 6.4. For the norm without singularity, we have

$$
\begin{equation*}
|\partial \rho|_{1+\sigma} \leq C K^{2(1+\sigma) / \sigma+1} . \tag{6.14}
\end{equation*}
$$

Proof. We take $\left\{\hat{a}^{i j}(t, v)\right\}$ as in (6.10) and $\hat{b}^{i}=\hat{c}^{i}=0$. Then, for each $k$, we define $\hat{u}(t, v)$, $\left\{\hat{f}^{i}(t, v)\right\}, \hat{c}^{0}(t, v)$ and $\hat{g}(t, v)$, respectively, by

$$
\begin{align*}
& \hat{u}(t, v)=\left\{\begin{aligned}
\rho_{v_{k}}(t-1, v), & t \in[1, T+1], \\
\hat{V}(t, v), & t \in[0,1) .
\end{aligned}\right. \\
& \hat{f}^{i}(t, v)=\left\{\begin{aligned}
f^{i,(1)}(\rho(t-1, v)), & t \in[1, T+1], \\
f^{i,(1)}\left(\rho_{0}(v)\right), & t \in[0,1),
\end{aligned}\right.  \tag{6.15}\\
& \hat{c}^{0}(t, v)=\left\{\begin{array}{rr}
K f^{\prime}(\rho(t-1, v)), & t \in[1, T+1], \\
0, & t \in[0,1),
\end{array}\right. \\
& \hat{g}(t, v)=\left\{\begin{aligned}
0, & t \in[1, T+1], \\
-2 \hat{h}(t, v), & t \in[0,1),
\end{aligned}\right.
\end{align*}
$$

where $\hat{V}(t) \equiv \hat{V}_{k}(t):=V(1-t)$ is defined from the solution $V(s), s \in[0,1]$ of the equation

$$
\partial_{s} V=L_{\rho_{0}} V-\partial_{v_{i}} f^{i,(1)}\left(\rho_{0}\right), \quad s \in(0,1]
$$

with initial value $V(0)=\partial_{v_{k}} \rho_{0}$, and $\hat{h}(t, v):=-L_{\rho_{0}} \hat{V}(t, v), t \in[0,1]$, where $L_{\rho_{0}}$ is the same as in the proof of Lemma 6.3. Then, $\hat{V}(t)$ satisfies the equation

$$
\partial_{t} \hat{V}=-L_{\rho_{0}} \hat{V}+\partial_{v_{i}} f^{i,(1)}\left(\rho_{0}\right)=L_{\rho_{0}} \hat{V}+2 \hat{h}+\partial_{v_{i}} f^{i,(1)}\left(\rho_{0}\right)
$$

Note that $h(t):=\hat{h}(1-t)=-L_{\rho_{0}} V(t)$ satisfies the equation

$$
\partial_{t} h(t)=L_{\rho_{0}} h(t)+L_{\rho_{0}} \partial_{v_{i}} f^{i,(1)}\left(\rho_{0}\right)
$$

and $h(0)=-L_{\rho_{0}} \partial_{v_{k}} \rho_{0}$. Thus, by applying Duhamel's formula

$$
h(t)=e^{t L_{\rho_{0}}} h(0)+\int_{0}^{t} e^{(t-s) L_{\rho_{0}}} L_{\rho_{0}} \partial_{v_{i}} f^{i,(1)}\left(\rho_{0}\right) d s
$$

with the semigroup $e^{t L_{\rho_{0}}}$ generated by $L_{\rho_{0}}$, which is a contraction under the sup-norm by the maximum principle, we see

$$
\|h(t)\|_{\infty} \leq\left\|L_{\rho_{0}} \partial_{v_{k}} \rho_{0}\right\|_{\infty}+\left\|L_{\rho_{0}} \partial_{v_{i}} f^{i,(1)}\left(\rho_{0}\right)\right\|_{\infty}<\infty, \quad t \in[0,1],
$$

since $\rho_{0} \in C^{4}\left(\mathbb{T}^{d}\right)$ by the condition (1.12). So $G=\|\hat{g}\|_{\infty} \leq C$.
This shows (6.14) by applying (6.12) for the extended solution defined on $[0, T+1]$.
These two lemmas also imply an estimate for $\partial_{t} \rho$. Indeed, expanding the right-hand side of (1.11) by noting $D_{i j}(\rho) \in C^{\infty}([0,1])$, and then applying (6.9) and (6.14), we obtain

$$
\begin{equation*}
\left\|\partial_{t} \rho\right\|_{\infty} \leq C K^{2(1+\sigma) / \sigma+1} \tag{6.16}
\end{equation*}
$$

Third, we take the derivative of (6.11) in $v_{\ell}$ and obtain

$$
\begin{equation*}
\partial_{t} \rho_{v_{k} v_{\ell}}=\partial_{v_{i}}\left\{D_{i j}(\rho) \partial_{v_{j}} \rho_{v_{k} v_{\ell}}\right\}-\partial_{v_{i}} f^{i,(2)}(\rho)+K f^{\prime}(\rho) \rho_{v_{k} v_{\ell}}+K f^{\prime \prime}(\rho) \rho_{v_{k}} \rho_{v_{\ell}}, \tag{6.17}
\end{equation*}
$$

where

$$
f^{i,(2)}(\rho)=-\sum_{j=1}^{d}\left\{D_{i j}^{\prime}(\rho) \rho_{v_{\ell}} \rho_{v_{j} v_{k}}+D_{i j}^{\prime \prime}(\rho) \rho_{v_{\ell}} \rho_{v_{k}} \rho_{v_{j}}+D_{i j}^{\prime}(\rho) \partial_{v_{\ell}}\left(\rho_{v_{k}} \rho_{v_{j}}\right)\right\} .
$$

We consider this equation to be a linear equation (4.22) for $u=\rho_{v_{k} v_{\ell}}$ with $a^{i j}=D_{i j}(\rho)$, $b^{i}=c^{i}=0, f^{i}=f^{i,(2)}$ (regarding all terms in $f^{i,(2)}$ already given), $c^{0}=K f^{\prime}(\rho)$ and $g=-K f^{\prime \prime}(\rho) \rho_{v_{k}} \rho_{v_{\ell}}$ (with all terms already given). Then, one can take $A=C K, F=$ $C K^{2}\left(K^{(1+\sigma) / \sigma}\right)^{3}$ by using (6.4), (6.9) and (6.14), $c_{2}=C K$ and $G=C K \cdot K^{2(1+\sigma) / \sigma}$. Thus, by (6.6), we obtain the estimate:

$$
|u|_{1+\sigma}^{*} \leq C\left(M\|u\|_{\infty}+K^{3(1+\sigma) / \sigma+2}\right)
$$

with $M=[1+A]^{(1+\sigma) / \sigma}+K$. Therefore, noting $\|u\|_{\infty}=\left\|\rho_{v_{k} v_{\ell}}\right\|_{\infty} \leq C K^{2(1+\sigma) / \sigma+1}$ by (6.14), we have

$$
\begin{equation*}
\left|\partial^{2} \rho\right|_{1+\sigma}^{*} \leq C K^{3(1+\sigma) / \sigma+2} . \tag{6.18}
\end{equation*}
$$

We can again use the same argument as above to remove the singularity near $t=0$.
Lemma 6.5. For the norm without singularity, we have

$$
\begin{equation*}
\left|\partial^{2} \rho\right|_{1+\sigma} \leq C K^{3(1+\sigma) / \sigma+2} . \tag{6.19}
\end{equation*}
$$

Proof. Take $\left\{\hat{a}^{i j}(t, v)\right\}$ as in (6.10), $\hat{c}^{0}(t, v)$ as in (6.15)) and $\hat{b}^{i}=\hat{c}^{i}=0$. Then, for each $k, \ell$, we define $\hat{u}(t, v),\left\{\hat{f}^{i}(t, v)\right\}$ and $\hat{g}(t, v)$, respectively, by

$$
\begin{align*}
& \hat{u}(t, v)=\left\{\begin{aligned}
\rho_{v_{k} v_{\ell}}(t-1, v), & t \in[1, T+1], \\
\hat{V}(t, v), & t \in[0,1) .
\end{aligned}\right. \\
& \hat{f}^{i}(t, v)=\left\{\begin{aligned}
f^{i,(2)}(\rho(t-1, v)), & t \in[1, T+1], \\
f^{i,(2)}\left(\rho_{0}(v)\right), & t \in[0,1),
\end{aligned}\right.  \tag{6.20}\\
& \hat{g}(t, v)=\left\{\begin{aligned}
K f^{\prime \prime}(\rho(t-1, v)) \rho_{v_{k}}(t-1, v) \rho_{v_{\ell}}(t-1, v), & t \in[1, T+1], \\
-2 \hat{h}(t, v), & t \in[0,1),
\end{aligned}\right.
\end{align*}
$$

where $\hat{V}(t) \equiv \hat{V}_{k, \ell}(t):=V(1-t)$ is defined from the solution $V(s), s \in[0,1]$ of the equation

$$
\partial_{s} V=L_{\rho_{0}} V-\partial_{v_{i}} f^{i,(2)}\left(\rho_{0}\right), \quad s \in(0,1],
$$

with initial value $V(0)=\partial_{v_{k}} \partial_{v_{\ell}} \rho_{0}$, and $\hat{h}(t, v):=-L_{\rho_{0}} \hat{V}(t, v), t \in[0,1]$. Then, $\hat{V}(t)$ satisfies the equation

$$
\partial_{t} \hat{V}=-L_{\rho_{0}} \hat{V}+\partial_{v_{i}} f^{i,(2)}\left(\rho_{0}\right)=L_{\rho_{0}} \hat{V}+2 \hat{h}+\partial_{v_{i}} f^{i,(2)}\left(\rho_{0}\right) .
$$

Note that $h(t):=\hat{h}(1-t)=-L_{\rho_{0}} V(t, v)$ satisfies the equation

$$
\partial_{t} h(t)=L_{\rho_{0}} h(t)+L_{\rho_{0}} \partial_{v_{i}} f^{i,(2)}\left(\rho_{0}\right)
$$

and $h(0)=-L_{\rho_{0}} \partial_{v_{k}} \partial_{v_{\ell}} \rho_{0}$. Thus, by Duhamel's formula similarly as before, we see

$$
\|h(t)\|_{\infty} \leq\left\|L_{\rho_{0}} \partial_{v_{k}} \partial_{v_{\ell}} \rho_{0}\right\|_{\infty}+\left\|L_{\rho_{0}} \partial_{v_{i}} f^{i,(2)}\left(\rho_{0}\right)\right\|_{\infty}<\infty,
$$

since $\rho_{0} \in C^{5}\left(\mathbb{T}^{d}\right)$ by the condition (1.12). Thus, $\|\hat{g}\|_{\infty}$ has the same bound by $G$ stated above. This shows (6.19) by applying (6.18) for the extended solution.

Finally for $\partial_{v_{k}} \partial_{t} \rho$, using (6.11), expanding the terms on the right-hand side and recalling $D(\rho), f(\rho) \in C^{\infty}([0,1])$, we obtain from (6.9), (6.14) and (6.19)

$$
\begin{equation*}
\left\|\partial_{v_{k}} \partial_{t} \rho\right\|_{\infty} \leq C K^{3(1+\sigma) / \sigma+2} . \tag{6.21}
\end{equation*}
$$

The estimate (2.3) follows from (6.9), (6.14), (6.16), (6.19), and (6.21).

## 7 Comparison theorem

The following lemma is standard and follows directly from the maximum principle. Recall that $f(0)>0$ and $f(1)<0$ for $f$ in the PDE (1.11) and $K>0$.

Lemma 7.1. For the solution $\rho(t, v)$ of (1.11), if $0<\rho_{-} \leq \rho_{0}(v) \leq \rho_{+}<1$, then we have $\rho_{-} \wedge \alpha_{-} \leq \rho(t, v) \leq \rho_{+} \vee \alpha_{+}$for all $t \geq 0$, where $\alpha_{-}=\min \{\alpha \in[0,1] ; f(\alpha)=0\}>0$ and $\alpha_{+}=\max \{\alpha \in[0,1] ; f(\alpha)=0\}<1$.

Proof. To show the upper bound, set $w(t, v):=\rho_{+} \vee \alpha_{+}+\varepsilon-\rho(t, v)$ for $\varepsilon>0$ small enough such that $\rho_{+} \vee \alpha_{+}+\varepsilon<1$. Noting $w(0, v)>0$, assume that there exist $t_{0}>0$ and $v_{0} \in \mathbb{T}^{d}$ such that $w(t, v)>0$ for $t \in\left[0, t_{0}\right)$ and $w\left(t_{0}, v_{0}\right)=0$. Then, we have

$$
\begin{align*}
& \partial_{t} w\left(t_{0}, v_{0}\right)-\sum_{i, j=1}^{d} \partial_{v_{i}}\left\{D_{i j}(\rho) \partial_{v_{j}} w\right\}\left(t_{0}, v_{0}\right)  \tag{7.1}\\
& \quad=-K f\left(\rho\left(t_{0}, v_{0}\right)\right)=-K f\left(\rho_{+} \vee \alpha_{+}+\varepsilon\right)>0 .
\end{align*}
$$

However, we see that $\partial_{t} w\left(t_{0}, v_{0}\right) \leq 0$ and, since $w\left(t_{0}, \cdot\right)$ takes the minimum value 0 at $v=v_{0}$, recalling (1.8) and (1.9) for $D(\rho)$, similar to [5], p.345, p. 390, we have

$$
\sum_{i, j=1}^{d} \partial_{v_{i}}\left\{D_{i j}(\rho) \partial_{v_{j}} w\right\}\left(t_{0}, v_{0}\right) \geq 0
$$

This contradicts with (7.1) and therefore we have that $\rho(t, v)<\rho_{+} \vee \alpha_{+}+\varepsilon$ for all $\varepsilon>0$ and $t \geq 0$. Thus the upper bound is shown. The proof for the lower bound is similar.

## 8 Non-degeneracy and boundedness of diffusion matrix

This problem was studied in [26] in more general setting reversible under the Gibbs measures. Nevertheless, we give the proof, in particular that of the lower bound, since it turns out to be explicit in the setting reversible under the Bernoulli measures.

Lemma 8.1. The bound (1.9) holds for $(\theta, D(\rho) \theta)$.
Proof. The upper bound $(\theta, D(\rho) \theta) \leq c^{*}|\theta|^{2}$ is easily obtained by taking $F=0$; see [26]. To show the lower bound, noting $\pi_{0, x}\left(\eta_{x}-\eta_{0}\right)=-2\left(\eta_{x}-\eta_{0}\right)$ for $x:|x|=1$, we have

$$
\begin{aligned}
\left\langle\left(\eta_{x}-\eta_{0}\right) \pi_{0, x}\left(\sum_{y} \tau_{y} \theta \cdot F\right)\right\rangle_{\rho} & =-2 \sum_{y}\left\langle\left(\eta_{x}-\eta_{0}\right) \tau_{y} \theta \cdot F\right\rangle_{\rho} \\
& =-2 \sum_{y}\left\langle\left(\eta_{x+y}-\eta_{y}\right) \theta \cdot F\right\rangle_{\rho}=0 .
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
|\theta \cdot x|\left\langle\left(\eta_{x}-\eta_{0}\right)^{2}\right\rangle_{\rho} & =\left|\left\langle\left(\eta_{x}-\eta_{0}\right)\left(\theta \cdot x\left(\eta_{x}-\eta_{0}\right)-\pi_{0, x}\left(\sum_{y} \tau_{y} \theta \cdot F\right)\right)\right\rangle_{\rho}\right| \\
& \leq\left\langle\left(\eta_{x}-\eta_{0}\right)^{2}\right\rangle_{\rho}^{1 / 2}\left\langle\frac{c_{0, x}}{c_{*}}\left(\theta \cdot x\left(\eta_{x}-\eta_{0}\right)-\pi_{0, x}\left(\sum_{y} \tau_{y} \theta \cdot F\right)\right)^{2}\right\rangle_{\rho}^{1 / 2}
\end{aligned}
$$

Then, taking the square and summing in $x:|x|=1$ in both sides, we obtain

$$
(2 \chi(\rho))^{2} \sum_{|x|=1}|\theta \cdot x|^{2} \leq \frac{4 \chi(\rho)}{c_{*}}(\theta, \widehat{c}(\rho ; F) \theta)
$$

for every $F \in \mathcal{F}_{0}^{d}$. This implies the lower bound $(\theta, D(\rho) \theta) \geq c_{*}|\theta|^{2}$.

## Acknowledgements

The author thanks Chenlin Gu for helpful discussions, especially for his deep insights from the quantitative homogenization and its extension to the hydrodynamic limit. This work was supported in part by the International Scientists Project of BJNSF, No. IS23007.
