# M ultipole invariants and non-G aussian ity 

$K$ ate Land and Joao M agueijo ?

Theoretical Physics G roup, Im perial C ollege, P rince C onsort R oad, London SW 7 2BZ, U K

ABSTRACT
W e propose a fram ew ork for separating the inform ation contained in the CM B multipoles, $a^{\prime} m$, into its algebraically independent com ponents. T hus we cleanly separate inform ation pertaining to the pow er spectrum, non $G$ aussianity and preferred axis e ects. The form alism builds_upon the recently proposed_m ultipole vectors (Copin H uterer \& Starkm an 2003;'Schw arz \& al2004;'K atz \& W eeks 20041) , and we elucidate a few features regarding these vectors, nam ely their lack ofstatisticalindependence for a G aussian random process. In a few cases we explicitly relate our proposed invariants to com ponents of the $n-$ point correlation function (pow er spectrum, bispectrum ). W e nd the invariants' distributions using a mixture of analyticaland num ericalm ethods. W e also evaluate them for the co-added W M AP rst yearm ap.

K ey w ords: cosm ic m icrow ave background -G aussianity tests - statistical isotropy.

## 1 IN TRODUCTION

 (2003) has led us to a new era in observational cosm ology. Yet, various claim s for lunexpected" non-G aussian signals cast a shadow on the parity of the data copio
 $=0^{2}=2$ 'al200 ${ }^{\prime}$;'Hansen \& al 2004''H ansen, B anday \& G orski 2004;
 2003, tasson \& Wadelt
 (2004). G iven that there is no plausible theoretical explanation for these signals, a natural worry is that the $m$ aps are not, after all, fiully free from system atics errors or galactic contam ination.

M ost notably several groups have reported evidence for a preferred axis being selected by large-angle uctuations, either in the form ofm ultipole planarity N-liveira-Costa \& al , $2004 ;$ 'Copi, Huterer \& Stankm an $2003 ;$ Schwarz $\alpha$ al $2001_{1}^{\top}$ coles \& al 20031), N orth-South asym $m$ etries in the power spectrum, three-point function,orbispectrum Eriksen d al "2004a'; Hansen, B anday \& G orski 2004; 'iand \& M agueip 20041 , as well as using other m ethods $\mathbb{E}$ riksen \& al 2004b; Hansen \& al 2004i).

In assessing these asym $m$ etries it is im portant to distinguish issues of non-G aussianity (which should be rotationally invariant) from those of anisotropy (existence of a preferred axis). A part from a subtlety in the de nition of statistical ensem ble (Ferreira \& M agueijo 1997l) these issues should be clearly separated.U nfortunately no system atic ap-

[^0]proach for extracting all the independent invariants under rotations from a given set ofm ultipoles, a'm g has been proposed. The form alism of C opi, H uterer \& Starkm an (2003) does not produce invariants. The invariant ntpoint comelation function Magueijo 1995; Ferreira, M agueijo \& G orski 199\%; $M$ agueijo 200d; ${ }^{\text {M }}$ agueijo \& $M$ edeiros 2003), on the other hand, is aw kw ard to apply and often contains redundant inform ation.

In this letter we rem edy this de ciency in the current form alism.

## 2 STATEMENTOFTHE PROBLEM

M ultipoles are irreducible representations of SO (3), so their $2^{\prime}+1$ degrees of freedom should split into 2 ' 2 invariants and 3 rotational degrees of freedom. Ideally we would like to process the fa, $g$ for a given $m$ utipole ' into the power spectrum $C$, (the G aussian degree of freedom), 2' 3 invariant $m$ easures of non-G aussianity, and a system of axes (assessing isotropy). In addition one should build 3 invariants perm ultipole pair, for exam ple the E uler angles relating the tw o sets ofm ultipole axes. T he latter encode inter-scale correlations.

N o one has ever accom plished th is project for general , but see $\bar{M}$ M agueijo (1995) for a Q uadrupole solution. M ultipoles are equivalent to sym $m$ etric traceless tensors of rank '. The problem is then to extract the independent invariant contractions of these tensors plus a system of axes \{ a generalisation of the concept of eigenvalues and eigenvectors. Typically the invariants produced by this form alism are related to the $n$ point correlation function (bispectrum , trispectrum, etc.) The form alism becom es very com -
plicated very quickly, and no system atic breakdown of independent $n$ point correlation function com ponents has ever been achieved.

A ltematively one $m$ ay extract from the fa،m $g$ a length scale and 'independent unit vectors (the m ultipole vectors) as proposed by Schwarz \& al (2004), and discussed further by K atz \& W eeks (2004). This approach is considerably sim pler and unsunprisingly it has been taken further. H ow ever we see a (correctable) problem with this approach. T hem ultipole vectors are not rotationally invariant, and so they m ix up the issues of isotropy and non-G aussin ity. W e propose to correct this shortcom ing by taking an appropriate num ber of independent inner products betw een these vectors. T hese are the sought-after invariants, and in som e sim ple cases we relate them to the $n$ point correlation function. W e will also extract from the multipole vectors a system of axes, encoding the m ultipole directional in form ation. It is these ax is that are to be used when testing isotropy.

## 3 THEEXAMPLEOFTHEQUADRUPOLE

W e start by considering the quadrupole, which as show $n$ in $M$ agueijo (1995!) $m$ ay be $w$ ritten as

$$
\begin{equation*}
T_{2}=Q_{i j} X^{i} x^{j} \tag{1}
\end{equation*}
$$

$w$ here $Q_{i j}$ is a sym $m$ etric traceless $m$ atrix and $x^{i}$ are cartesian coordinates on the unit sphere. From this $m$ atrix one $m$ ay extract three eigenvectors and tw o independent com binations of invariant eigenvalues $i$. T hese are essentially the power spectrum $C_{2}$ (related to the sum of the squares of i) and the bispectrum B 222 (related to the determ inant of the $m$ atrix, or the product of i).
. - In contrast, follow ing the form alism of atz \& eek (2004) one writes

$$
\begin{equation*}
T_{2}=A_{2} \quad L_{i}^{1} L_{j}^{2} \quad \frac{1}{3}{ }_{i j} L^{1} \quad L^{2} \quad x^{i} x^{j} \tag{2}
\end{equation*}
$$

$w$ here $A$ is a scale and $f L_{i}^{1} ; L_{i}^{2} g$ are two units vectors, encoding the inform ation on non-G aussianity and anisotropy.
$T$ he vectors $\mathrm{fL}_{\mathrm{i}}^{1} ; \mathrm{L}_{i}^{2} \mathrm{~g}$ are not invariant, but one can construct an_invariant by taking $X X_{-}=L^{1} \quad \mathcal{L}^{2}$. A s pointed out to us by 'Starkm an \& Schwarz (2004i), one m ay easily check that the eigenvectors of $Q$ are
$\mathrm{V}^{1}=\mathrm{L}^{1}+\mathrm{L}^{2}$
$\mathrm{V}^{2}=\mathrm{L}^{1} \mathrm{~L}^{2}$
$\mathrm{V}^{3}=\mathrm{L}^{1} \mathrm{~L}^{2}$
These have corresponding eigenvalues $A(X+3)=6$, $A(X$ $3)=6$, and $A X=3$, respectively. U sing results in $M$ agueijd, ${ }^{1}(1995)$ one $m$ ay therefore prove that the power spectrum and buispectrum are:

$$
\begin{align*}
C_{2} & =\frac{\mathrm{A}_{2}^{2}}{6}\left(X^{2}+3\right)  \tag{6}\\
B_{222} & =\frac{\mathrm{A}_{2}^{3} \mathrm{X}}{2^{2} 3^{3}}\left(9 \quad X^{2}\right) \tag{7}
\end{align*}
$$

so that the norm alised bispectrum is
$I_{2}=\frac{B_{222}}{C_{2}^{\frac{3}{2}}}=\frac{X\left(9 X^{2}\right)}{\left(X^{2}+3\right)^{3=2}}$

Figure 1.The average distribution of the modulus of the 2, 3 dot products $X_{i j}$ ( $w$ ith the two anchor vectors chosen at random) form ultipoles ${ }^{\prime}=2$ 10. The dotted line corresponds to the analytical expression found for the quadrupole. W e have also plotted the invariant values for the W M AP rst year data, w ith the anchor vectors chosen at random (short lines along the bottom of each panel).
$T$ hese form ulae bridge the two form alism $s$.
It was proved in $M$ agueijo $(1995)$ that for a $G$ aussian process $\mathrm{C}_{2}, \mathrm{I}_{2}$ and the eigenvectors are independent random variables, and that $I_{2}$ is uniform ly distributed in the range [ $1 ; 1$ ] (and $C_{2}$ has a ${ }_{5}^{2}$ distribution). W e thus can prove that $X$ is statistically independent from $C_{2}$ (but not from A) and from the eigenvectors. By directly evaluating the Jacobian of the transform ation we nd that its distribution is
$P(X)=27 \frac{1 X^{2}}{\left(X^{2}+3\right)^{5=2}}$
that is, 止 is not uniform. W e have con m ed th is result w ith $M$ onte-C arlo sim ulations (see Fig. $\bar{I}_{1}^{1}$, top left panel).
$T$ his elucidates an interesting feature of multipole vectors. Even though they are algebraically independent (in the sense that they contain no redundant in form ation given a concrete quadrupole realization) they are not statistically independent. If vectors $L^{1}$ and $L^{2}$ were statistically isotropic (which they are) and statistically independent, then X would be uniform ly distributed. A s (9, $\mathbf{g}_{1}$ ) show $s$ this is not the case; hence vectors $L^{1}$ and $L^{2}$ are statistically correlated. Speci cally they prefer being orthogonal to being aligned.

## 4 THEGENERALPROCEDURE

For a generalm ultipole we have 'vectors and we could take as invariants allpossible inner products betw een them. Th is

Figure 2．The distribution of the m odulus of the dot products form ultipoles＇$=2 \quad 10, \mathrm{w}$ ith anchor vectors $\mathrm{L}^{1}$ and $\mathrm{L}^{2}$ chosen as the m ost orthogonal pair of $m$ ultipole vectors．T he solid lines are for dot products $X_{1 i}$ and $X_{2 i}$ ，and the dotted line show $s$ the $\mathrm{X}_{12}$ distribution．TheW M AP results are also plotted（short lines along the bottom，dashed line the $\mathrm{X}_{12}$ result）．
w ould clearly lead to m uch redundant inform ation，in con－ tradiction $w$ ith the requirem ents laid dow $n$ in Section A possible way out is to select two \anchor＂vectors $\mathrm{L}^{1}$ and $\mathrm{L}^{2}$ ，consider their dot product $\mathrm{X}_{12}=\mathrm{L}^{1} \quad \mathrm{Z}^{1}$ ，and then for 36 i6 the two products $X_{1 i}=L^{1}$ L and $X_{2 i}=L^{2}$ 亡． W e thus obtain $2^{\prime} 3$ algebraically independent invariants． In Fig．${ }^{n}$＇，we plot their distribution for 26 ＇ 610 after the order and direction（ ）of the＇vectors has been random ised． The anchor vectors $\mathrm{L}^{1}$ and $\mathrm{L}^{2}$ are therefore selected at ran－ dom，so that all $\mathrm{X}_{\mathrm{ij}}$ invariants for a given multipole have the sam e distribution． w e checked that the invariants x are uncorrelated．A swe can this distribution is＇dependent， and the tendency for $m u l t$ ipole vectors to soek orthogonal directions is less pronounced for higher multipoles． W e have also plotted these invariants as com puted forthe W－M AP＿co－ added $m$ asked rst year $m$ ap（details in＇工and $\underset{\text { 区 }}{ }$ M agueijo＇ （2004）I．No evidence for non－G aussian ity is found，but we defer a closer scrutiny to a fiture publication．

The proposed procedure provides an interesting $G$ aus－ sian ity test．In particular it can be easily applied to extract all the relevant inform ation for high＇；in contrast isolat－ ing such inform ation from the $n$－point correlation function is $m$ ost cum bersom $e$ ．H ow ever the suggested algorithm suf－ fers from the drawback that the anchor vectors $\mathrm{L}^{1}$ and $\mathrm{L}^{2}$ are selected at random，and so the procedure is not repro－ ducible．

W em ay correct this by in posing a criterium for their selection，for exam $\mathrm{ple} \mathrm{L}^{1}$ and $\mathrm{L}^{2} \mathrm{~m}$ ay be taken as the m ost orthogonal am ong the given＇vectors． W e m ay then form
the \eigenvectors＂（three orthogonal vectors）：

$$
\begin{align*}
\mathrm{V}^{1} & =\mathrm{L}^{1}+\mathrm{L}^{2}  \tag{10}\\
\mathrm{~V}^{2} & =\mathrm{L}^{1} \mathrm{~L}^{2}  \tag{11}\\
\mathrm{~V}^{3} & =\mathrm{L}^{1} \mathrm{~L}^{2} \tag{12}
\end{align*}
$$

as the natural variables for encoding the m ultipole direction－ ality．For invariants we $m$ ay take the power spectrum and the 2＇ 3 quantities：

$$
\begin{align*}
X_{12} & =L^{1}  \tag{13}\\
X_{1 i} & =L^{1}  \tag{14}\\
X_{2 i} & =L^{2} \tag{15}
\end{align*}
$$

（for 36 i 6 ｀）．These encode all the relevant non－G aussian degrees of freedom．

The transform ation from $a_{m}$ into these variables is invertible（up to discrete uncertainties related to branch choice）and provides a solution to our problem，as phrased in Section 1 ．The proposed variables for a given multipole ＇are the power spectrum C，（G aussian degree of freedom）， the 2， 3 inner products $X$（non－redundant non－G aussian invariants），and the orthogonal vectors $\mathrm{fV}^{1} ; \mathrm{V}^{2} ; \mathrm{V}^{3} \mathrm{~g}$（ m ea－ sures of an isotropy）．T he procedure reduces to the one found for the quadrupole when $v=2 . W$ ithin this fram ew ork the inter－＇correlations are $m$ easured by the Euler angles relat－ ing the system s of axes $\mathrm{fV}^{1} ; \mathrm{V}^{2} ; \mathrm{V}^{3} \mathrm{~g}$ associated w ith each pair ofm ultipoles．T hese should be uniform ly distributed for a G aussian distribution or indeed for any theory in which the various＇are uncorrelated．

In F ig． anchor vectors $L^{1}$ and $L^{2}$ de ned as the $m$ ost orthogonal． W e have used 12，500 realizations to $m$ ake these histogram $s$ ． $P\left(X_{12}\right)$ peaks around zero．The other $X$ distributions are the sam e．W e also plotted the invariants for theW MAP rst year data，again nding no evidence for non－G aussianity． W e have checked that the eigenvectors， $\mathrm{V}^{\text {i }}$ ，are uniform ly distributed．

N otice that the invariants $X$ cannot be independent variables，since their ranges of variation are interconnected． $T h$ is is to be com pared w ith the lack of independence am ong the various vectors $L^{i}$ ，as dem onstrated in the previous Sec－ tion．

N aturally we could have de ned the two anchor vec－ tors $L^{1}$ and $L^{2}$ in di erent ways，for exam ple the tw o most aligned vectors．The invariant $X_{12}$ would then be peaked around one．W e plot the counterpart of Fig． temative de nition in Fig． $\bar{B}_{1}^{1}$ ．

## 5 BRIDGINGTHETWOFORMALISMS

For higher m ultipoles，relating the proposed form alism and the $n$ point correlation function，as done in Section for the quadrupole，becom es very involved．For instance，for the octopole the counterpart of（ $\left(l_{1}^{1}\right)$ and $(\mathbb{4})$ is：

$$
\begin{equation*}
T_{3}=Q_{i j k} x^{i} x^{j} x^{k}=A_{3} \quad L_{i}^{1} L_{j}^{2} L_{k}^{3} \quad \frac{1}{3}{ }_{i j} R_{k} \quad x^{i} x^{j} x^{k} \tag{16}
\end{equation*}
$$

where one should note that term $s$ in fi；j；kg are sym－ $m$ etrized．$T$ he rem ainder $R_{k}$ is：
$R_{k}=\frac{3}{5} L^{(1} \quad L L_{k}^{3)}$

Figure 3. The distribution of the m odulus of dot products for multipoles ${ }^{\prime}=2 \quad 10, \mathrm{w}$ ith anchor vectors $\mathrm{L}^{1}$ and $\mathrm{L}^{2}$ chosen as the $m$ ost aligned pair of $m$ ultipole vectors. The solid lines are for dot products $\bar{x}_{1 i} \overline{a n d}^{-\bar{x}_{2 i}}$, and the dotted line show ${ }^{-}$the
 along the bottom, dashed line the $X_{12}$ result).
and a set of 2' 3 non-G aussian statistics $\{$ and a set of axes encoding the m ultipole directionality. T he E uler angles relating sets of axes associated w ith pairs ofm ultipoles m easure inter-' correlations. T his provides an elegant answ er to a long unsolved problem \{ how to process the inform ation contained in a given m ap into its relevant non-redundant degrees of freedom.

Even though we have com puted som e of the proposed invariants for theW M AP rst yearm ap, we defer to a future publication a m ore system atic application of this fram ew ork to real data. W e stress that the form alism is easily applicable for high ' multipoles. This is to be contrasted with the $n$-point correlation function. E ven though it is trivial to evaluate the bispectrum at high ' Land \& M agueijo 2004) it becom es very di cult to distill all the non-redundant inform ation contained in a given multipole in term $s$ of su ciently high order com ponents of the correlation function. The proposed form alism is farm ore e cient.

## ACKNOW LEDGEMENTS

W e would like to thank D om inik Schwarz, G lenn Starkm an and Je W eeks for discussion and help $w$ ith thispro ject. $T$ he results in thispaper have been derived using the H EA LP ixil package (G orski, Hivon \& W andelt 199\%), aswellas the pub_licly available codes described in "C opi, H uterer \& Starkm an'
 national cosm ology supercom puter.

## 6 C ONCLUSIONS

H arm on ic (Fourier) space is the naturalarena for com paring theory and observation for $G$ aussian theories. In severalpast studies it was also found to be a useful ground for testing the hypothesis of G aussian ity. In this paper we showed further that the degrees of freedom in the spherical harm on ic com ponents farm $g$ can be sim ply separated into a set of algebraically independent invariants \{ the pow er spectrum
