#### Abstract

Using the Boltzm ann equation with a Langevin-like tem describing the stochastic force in a baryon-photon plasm a, we investigate the in uence of the incoherent electron-photon scattering on the subhorizon evolution of the cosm ic m icrow ave radiation. The stochastic uctuation caused by each collision on average is found to be sm all. Nevertheless, it leads to a signi cant B row nian drifting of the phase in the acoustic oscillation, and the coherent oscillations cannot be $m$ aintained during their dynam ical evolution. As a consequence, the proposed D oppler peaks probably do not exist.

 PACS num bers: 98.70.V c, 98.80 Es , 05.40 .+ jThe anisotropies of the cosm ic $m$ icrow ave background (CMB) provide a key to the understanding of the origin of prim ordial uctuations and the them al history of the early universe. The spectrum of the CM B anisotropy on large angular scales has been found to be consistent w ith the in ationary scenario of the early universe'[i]]. It is generally believed that $m$ any cosm ological param eters can be determ ined from the ne structures in the power spectrum of CM B anisotropy. Am ong them, the possible existence of D oppler peaks $\{$ the peaks in the CM B anisotropy spectrum on an angular scale of about one degree or less has attracted $m$ uch attention End $_{1}$.

It has been shown theoretically that the am plitude and the position of these D oppler peaks are functions of the spatial curvatures, $m$ ass density, reionization tim e, cosm ological constant etc. Thus, a precision $m$ easurem ent of the $D$ oppler peaks $m$ ay provide us an e ective tool to determ ine various cosm ic param eters. H ow ever, the observed am plitudes of the CM B anisotropy on degree-scale have not so farbeen very conchusive in determ ining the existence of the D oppler peaks. Indeed, som e observations seem s to exhibit high am plitudes as expected in a D oppler-peak scenario, while others show no peak am plinudes [2̄1]. O ne m ay assert at this stage that the expected peaks have not yet been clearly identi ed in current data, but would be determ ined by a new generations of the CM B anisotropy observations.

In this letter, we shall take a di erent approach to reexam ine the theoretical foundation of the prediction of the D oppler peaks. In particular, we shall argue based on a stochastic Boltzm ann equation that the coherence of acoustic oscillations in the baryon-photon plasm a will be largely disturbed, and $m$ ay even be totally erased if the stochastic force of the incoherent scattering is included. In the standard theory of the CM B evolution $\left.\left\lvert\, \begin{array}{l}\bar{\beta} \\ \hline\end{array}\right.\right]$, the acoustic oscillations in the baryon-photon plasm a on subhorizon scales are treated coherently, i.e. di erent modes are frozen at di erent phases of their oscillation. The position of the D oppler peaks is then calculated by the phase at the recom bination. H ow ever, the inclusion of correlation due to the stochastic term in the baryon-photon plasm a w ill lead to a phase random ization. The coherence of the oscillations could be $m$ aintained if there is a $m$ echanism for providing a negative entropy current to prevent the decoherence due to the
phase random ization (like a laser). U nfortunately, no such mechanism exists in the epoch of recom bination, while the existence of a stochastic force term in the kinetic equation is inevitable in a system with dissipation. W e shall show that the phase random izations introduced by the incoherent electron-photon scattering are, indeed, substantial, and as a result, the D oppler peaks will be erased. Instead, one expects a large dispersion of the am plitudes in the CM B power spectrum due to di erent realizations on subhorizon scales, re ecting the stochastic nature of the phases. W e suggest that the dispersed observations of the CM B angular power spectrum on degree-scale, though very coarse at this stage, are in support of our view .

Let us use conventional notations in the theory of the CM B anisotropy [13, 1 . Since the coherent oscillations of the D oppler peaks act only on subhorizon scales, the choioe of gauge is irrelevant for our calculation. The evolution of the photon distribution function $f(t ; x ; p)$ is calculated by the Boltzm ann equation

$$
\begin{equation*}
\frac{d f}{d t} \quad \frac{@ f}{@ t}+\frac{d x^{i}}{d t} \frac{@ f}{@ x^{i}}+\frac{d p_{0}}{d t} \frac{@ f}{@ p_{0}}+\frac{d}{d t} \frac{\varrho f}{@ i}=C[f]: \tag{1}
\end{equation*}
$$

where $i$ is the direction cosines of $p_{i} w$ th respect to the corresponding spatial coordinate. The left hand side of eq.(1) describes the free-stream ing, and the right hand side is the collision term given by

$$
\begin{align*}
C[f]= & d q d q^{Z} d p w\left(p ; q ; p^{0} ; q^{0}\right) \\
& f g\left(t ; x ; q^{0}\right) f\left(t ; x ; p^{0}\right)[1+f(t ; x ; p)] \\
& g(t ; x ; q) f(t ; x ; p)\left[1+f\left(t ; x ; p^{0}\right)\right] g \tag{2}
\end{align*}
$$

$w$ here $g$ is the electron distribution function, and the collision rate $W$ is determ ined by the C om pton scattering betw een electron and photon from state $\left(q^{0} ; p^{0}\right)$ to ( $q ; p$ ).

It is well know $n$ that the Boltzm ann equation in (1) is derived under the assum ption of a m olecular chaos and is applicable if the uctuations caused by the incoherent collisions are negligible. These uctuations give rise to a stochastic foroe term in hydrodynam ics '[i] 4 ], govemed by the uctuation-dissipation theorem. Sim ilarly, these uctuations can be taken
into account by an additionalLangevin-like force term in the Boltzm ann equation should then be replaced by

$$
\begin{equation*}
\frac{d f}{d t}=C[f]+r(t ; x ; p) \tag{3}
\end{equation*}
$$

where the stochastic force, $r$, is characterized by its correlations:

$$
\begin{gather*}
h r(t ; x ; p) i=0 ;  \tag{4}\\
h r\left(t_{1} ; x_{1} ; p_{1}\right) r\left(t_{2} ; x_{2} ; p_{2}\right) i=\frac{1}{2} N \quad\left(t_{1} \quad \frac{\hbar}{2}\right) \\
\left(\mathrm{x} \quad \mathrm{x}_{2}\right) \quad d q d q^{0} d p d p \% \quad\left(q ; p ; q^{0} ; p^{0}\right) \quad\left(p_{1}\right) \\
\left(p_{2}\right) g\left(t_{1} ; x_{1} ; q\right) f\left(t_{1} ; x_{1} ; p\right)\left[1+f\left(t_{1} ; x_{1} ; p^{0}\right)\right] \tag{5}
\end{gather*}
$$

where h::i is an average over the stochastic e ect (ie. over di erent realizations), N is the total num ber of photons, and the function $(P)$ is de ned by

$$
\begin{array}{r}
(\mathrm{P})=\left(\begin{array}{ll}
\mathrm{P} & \left.\mathrm{q})+\begin{array}{ll}
\mathrm{P} & \mathrm{p}
\end{array}\right) \\
(\mathrm{P} & \mathrm{q}
\end{array} \mathrm{(P} \quad \mathrm{p}\right):
\end{array}
$$

It is im portant to note that eqs.(3)-(6) are applicable not only in a linear approxim ation but

In principle, to study the uctuations in the baryon-photon plasm a, we should also consider the stochastic term $s$ in the equation of baryonic $m$ atter. $H$ ow ever, since the linear uctuations given by independent G aussian random \foroes" are additive, the stochastic term $s$ in the baryonic equation $w$ ill increase the e ects of uctuations considered in this paper. To illustrate the $m$ ain e ect of electron-photon scattering in the presence of the D oppler peaks, we shall only consider the contribution from stochastic term $r$ in photon's equation. In this case, the electron distribution $g(t ; x ; q)$ can be treated as an extemal source. For a Thom son scattering, photons do not exchange energies w thelectrons. The q-distribution of electrons do not involved in the evolution, and we need only the num ber density distribution of electrons $n_{e}={ }^{R} d q g(t ; x ; q)$. In this case, the distribution of the
photon energy $p$ is also unchanged, the perturbation of the CM B can be described by the anisotropy of the brightness tem perature

$$
\begin{equation*}
(t ; x ;)={\frac{1}{4^{2}}}^{z}{f p^{3} d p} \frac{1}{4} ; \tag{7}
\end{equation*}
$$

where $=\left({ }^{2}=15\right) \mathrm{T}^{4}$ is the $m$ ean energy density of photons. In term $s$ of , the photon distribution function can be approxim ately expressed as

$$
\begin{equation*}
f(t ; x ; p)=f_{T}(p)[1+4 \quad(t ; x ;)] \tag{8}
\end{equation*}
$$

where $f_{T}=1=[\exp (p=T) \quad 1]$.
From eqs.(1) and (8), one nds that should satisfy

$$
\begin{align*}
& \frac{\varrho}{@}(+)+\frac{i}{@ x^{i}}( +)+\frac{i}{@} \frac{@}{\varrho} \\
&\left(0 \quad+i V_{b}^{i}+\frac{1}{10} Q\right)+R \tag{9}
\end{align*}
$$

where and are the $N$ ew tonian potential and the space curvature perturbation, respectively. $={ }^{R}(1+z) d t$ is the conform al tim $e, z$ the redshifl, $v_{b}$ the baryonic ( uid) velocity,
 operator of quadnupole, de ned asQ $\left(;{ }^{0}\right)={ }^{P}{ }_{m}^{2}={ }_{2} Y_{2 m}()(1=4)^{R} d^{0} Y_{2 m}(0)$. Obviously $\mathrm{Q} \mathrm{Q}=\mathrm{Q}$. The isotropic com ponent $\mathrm{O}(; \mathrm{x})$ is given by $0=0 \quad$, where $\mathrm{O} \quad(1=4)^{\mathrm{R}} \mathrm{d}$ is the m onopole projection operator, and $\mathrm{OO}=\mathrm{O}$. The term 0 appearing on the right-hand side ofeq. (9) indicates that $w$ thout an extemaldriving force (such $a s v_{b}$ ) the isotropic state is the \equilibrium " state in the kinetic evolution of the $T$ hom son scattering.

The stochastic term in eq. (9) is $R=\left(1=4{ }^{2}{ }_{r}\right)^{R} r p^{3} d p$, and its correlation function is given by

$$
\begin{align*}
& h R\left({ }_{1} ; \mathrm{x}_{1} ;{ }_{1}\right) \mathrm{R}\left({ }_{2} ; \mathrm{x}_{2} ; 2\right) \mathrm{i}= \\
& \frac{3}{8{ }^{4}} \frac{N}{16^{4}{ }_{r}^{2}} \quad(1 \quad 2) \quad\left(x_{1} \quad x_{2}\right) \\
& \left.\left.\stackrel{4}{4} 4^{\hbar^{4}} \begin{array}{llll}
1 & & & 2) \\
& & z & \frac{1}{2}\left(1+\cos ^{2}\right.
\end{array}\right)\right] \\
& \left.+2 f\left({ }_{1} ; x_{1} ; p ;{ }_{1}\right) f\left({ }_{2} ; x_{2} ; p ;{ }_{2}\right)+f\left({ }_{2} ; \mathrm{x}_{2} ; p ;{ }_{2}\right)\right] \tag{10}
\end{align*}
$$

where is the angle betw een 1 and 2 . Because eq. (9) is linear in , it reduces to eq. (1) by taking an average over the stochastic e ect. Thus, the calculation based on eq.(1) is actually only for $h$ i but not for, i.e. the uctuations due to the stochastic term $s$ are entirely overlooked in eq.(1). In the incoherent processes, the linear uctuations, $=\mathrm{h}$ i, caused by stochastic force R m ay not in general play a very im portant role. H ow ever, these uctuations lead to \forgetting history". T hus, the existence and $m$ aintenance of coherence should be seriously reconsidered.

Let us calculate the linear uctuations, ( $\mathbf{i x} ;$ ), at a given time around a solution to eq.(1). It is govemed by

$$
\begin{gather*}
\quad \frac{@}{@}+\frac{i @}{@ x^{i}}+\frac{i}{@} \frac{@}{i^{i}} \\
+\quad\left[1+\frac{1}{10} Q\right](\quad 0)=R^{0} \tag{11}
\end{gather*}
$$

where $R^{0}=(1 \quad 0) R$. The projection operator arises from the isotropic term 0 in eq.(9). The solution to eq.(12) can be generally expressed as

O bviously, both sides ofeq. (13) becom e zero upon an integration (1=4 ) $)^{R} d \quad$ because $O$ ( 1 $0)=0$.

The correlation functions of uctuations, such ash $\left(1 ; x_{1} ; 1\right)\left(2 ; x_{2} ; 2\right) i$, can be calculated from eqs.(10) and (12). For a at universe, the light path is a straight line in com oving coordinates $x$, and thus $\dot{i}=0$. The uctuation for the $m$ ode $(1 ; k)$ with $l>0$ is then

$$
\begin{aligned}
& \text { h } 1(; k) \quad{ }_{1}(; k) i= \\
& {\frac{1}{V^{2}}}^{\mathrm{z}} \mathrm{dx} x_{1} d x_{2} \operatorname{expf} \quad i k \quad\left(\begin{array}{ll}
\mathrm{x} & \left.\mathrm{x}_{2}\right) g
\end{array}\right. \\
& \frac{(21+1)^{2}}{64{ }^{2}} \mathrm{~d}_{1} \mathrm{~d}_{2} \mathrm{P}_{1}\left(\mathrm{k}_{0} \quad{ }_{1}\right) \mathrm{P}_{1}\left(\mathrm{k}_{0} \quad\right. \text { 2) } \\
& \mathrm{d}_{1} \mathrm{~d}_{2} \operatorname{expf} \quad{ }_{1}\left[1+\mathrm{Q}_{1}\right] \quad{ }_{2}\left[1+\mathrm{Q}_{2}\right] g
\end{aligned}
$$

$$
\mathrm{hR}^{0}\left(\quad 1 ; \mathrm{x}_{1} \quad 11_{1} ;{ }_{1}\right) \mathrm{R}^{0}\left(\quad 2 ; \mathrm{x}_{2} \quad 22_{2}\right) \mathrm{i}
$$

where $\mathrm{k}_{0}=\mathrm{k}=\mathrm{k} \mathrm{j}$ and V the volum e being considered. Since ( $\left.=\mathrm{k}\right) \quad 1$, the above equation can be sim pli ed by using eqs. (8) and (10) as

$$
\begin{align*}
& h_{1}(; k) \quad{ }_{1}(; k) i=\frac{0: 531 \quad 675}{14} \\
& \frac{(2 l+1)^{2}}{64^{2}}{ }_{Z} \mathrm{~d}_{1} \mathrm{~d}_{2} \mathrm{P}_{1}\left(\mathrm{k}_{0} \quad{ }_{1}\right) \mathrm{P}_{1}\left(\mathrm{k}_{0} \quad\right. \text { 2) } \\
& d e^{2} \quad\left(1 \quad O_{1}\right)\left(\begin{array}{ll}
1 & O_{2}
\end{array}\right) \\
& {\left[1+\left(e^{=10} 1\right) Q_{1}\right]\left[1+\left(e^{=10} 1\right) Q_{2}\right]} \\
& \stackrel{4}{4}_{4}^{4} \quad\left(\begin{array}{ll}
1 & 2)
\end{array} \frac{1}{2}\left(1+\cos ^{2} \quad\right)\right] \\
& \frac{1}{V}^{Z} d x h\left(\quad ; x_{1}\right) \quad\left(\quad ; \text {; }_{2}\right) i \tag{13}
\end{align*}
$$

 $\left[1+\left(\begin{array}{ll}\left(\begin{array}{ll}a & 1\end{array}\right) Q\end{array}\right]\right.$. The $m$ onopole projection factors $\left(1 \quad O_{1}\right)$ and ( $\left.1 \quad O_{2}\right)$ can be replaced by a unity operator when $l>0$. The two quadrupole projection term $s Q_{1}$ and $Q_{2}$ can be neglected because the term $e^{2}$ picks up the $m$ ain contribution in the integral from the region < $1 . U \operatorname{sing}$ the follow ing $m$ ode decom position

$$
\begin{align*}
& \frac{1}{V}^{z} d x h(; x ; 1) \quad(; x ; 2) i= \tag{14}
\end{align*}
$$

we have nally

$$
\begin{aligned}
& \text { hj } \quad 1(; k) j i=3: 91 \quad 10^{5} \\
& \frac{2 l+1}{3}{\frac{\mathrm{~V}}{}{ }^{2}}^{\mathrm{Z}} \mathrm{dkk}^{2}{ }_{\mathrm{l}^{0}}^{\mathrm{x}} \frac{1}{21^{0}+1} \overline{\mathrm{hj} \mathrm{l}^{0}(; \mathrm{k}) \mathrm{J}^{\mathrm{j} i}}
\end{aligned}
$$

$$
\begin{align*}
& {\frac{V}{2^{2}}}^{Z} k^{2} d k \frac{1}{2 l+1} \overline{h j{ }_{1}(; k)}{ }^{\text {fi }} \tag{15}
\end{align*}
$$

where the overline above $\mathrm{hj}_{1}(; k)$ 湭 denotes an average over the region from $\quad(1=$ ) to , and ( $1+; 0 ; 2 ; 0 j+; 0$ ) are the $C$ lebsch-G ordon coe cients. For large 1 , the second
(negative) term in the bracket eq.(16) is com pletely negligible. The rst term is independent of $l$ and $k$. This is expected since the correlation function of the corresponding stochastic force is isotropic in -space and uniform in $k$-space.

U sing the expression for a tem perature perturbation

$$
\begin{equation*}
\frac{T}{T}^{2}={\frac{V}{2^{2}}}^{\mathrm{Z}} \mathrm{dkk}^{2}{ }_{1}^{\mathrm{X}} \frac{1}{2 l+1} \overline{\mathrm{hj} 1(; k) \frac{\mathrm{J}}{\mathrm{j}} \mathrm{i}} ; \tag{16}
\end{equation*}
$$

one has

$$
\begin{equation*}
\frac{\mathrm{hj} \quad \mathrm{f}^{\mathfrak{f}} \mathrm{i}}{21+1}, 1: 30 \quad 10^{5} \mathrm{j} \mathrm{~T}=\mathrm{T} \text { f : } \tag{17}
\end{equation*}
$$

The 1 summ ation in eq.(16) should run up to $l_{n}$ ax where the electron-photon collision is frequent enough, i.e. to the scale about the photon $m$ ean free path $1=$. Therefore, $T=T$ in eqs.(16) and (17) should not be confused with ( $T=T$ ) obs given by observations with low resolutions, i.e. their window functions are on scales much larger than $l_{n}$ ax . For the observation of CM $R$ anisotropy w ith a resolution 1 , the uctuation is

$$
\begin{align*}
& \frac{T}{T}=x^{x^{1}} \frac{h j 1^{0} j^{1} i^{!}}{21^{0}+1} \\
& 3: 61 \quad 10^{3^{P}} \frac{\mathrm{p}}{1} \frac{\mathrm{~T}}{\mathrm{~T}}: \tag{18}
\end{align*}
$$

Therefore, the uctuations caused by the stochastic force $R$ are generally sm all, except for the case of a very high resolution observation.

H owever, the average of the uctuations in eqs.(15) and (18) is essentially over one collision tim e 1=. . In relation to coherent processes, we should study the cum ulative e ect of the uctuations over the entire period during which the coherence is to be m aintained '[i]. For the D oppler peaks, the period is from the tim e when the perturbation enters horizon to the tim e ofrecom bination, i.e. the duration of the subhorizon evolution before recom bination . The cum ulative e ect can be easily described by the phase uctuations of the oscillation. Use the expression ${ }_{1}(; k)=j j^{i}{ }^{1}$, where $j_{1}(; k) j$ and ${ }_{1}(; k)$ are the amplitude and phase, respectively. The equations of $1(; k)$ can then be derived from eq.(9) as

$$
\begin{align*}
& \rightarrow=\frac{k}{3}{ }^{1} \quad-+R_{0}  \tag{19}\\
& I=k \quad 0+\quad \frac{2}{5}{ }^{2} \quad\left(\begin{array}{ll}
1 & V_{0}
\end{array}\right)+R_{1}  \tag{20}\\
& I_{1}=k \frac{1}{21 \quad 1} \quad \frac{1+1}{21+3} \quad 1+1 \\
& { }_{1}+R_{1} \quad(1>2) \tag{21}
\end{align*}
$$

where

$$
\begin{equation*}
R_{1}=\frac{1}{V} \frac{2 l+1}{8}^{Z} d P_{1}\left(k_{0} \quad{ }^{Z}\right) d x e^{i k}{ }_{R} \tag{22}
\end{equation*}
$$

If the hierarchy of（21）－（23）is cut o at 21 －th order，they correspond to the equations for a system consisting of l coupled oscillators．W ithout the stochastic term $s R_{1}$ ，the oscillations are coherent and the phases of the oscillations are com pletely xed by initial conditions． $T$ he term $S R_{1}$ lead to a phase random ization．

We shall rst calculate the phase uctuations raised by B．A s the coupling between the photon and the baryon is tight and the peculiar gravitational potential is weakly tim e－ dependent in $m$ atter－dom inated regim e［了了了 $]$ ，the evolution of 0 is dom inated by the phase evolution $0($ ），which is approxim ately described by a W K B－like equation as

$$
\begin{equation*}
\frac{\mathrm{d}_{0}}{\mathrm{~d}}, \mathrm{kc}_{\mathrm{s}} \quad \frac{1}{2 \mathrm{~h}{ }_{0} \mathrm{i} \mathrm{kc}_{\mathrm{s}}} \frac{1}{\mathrm{~d}} \frac{\mathrm{dR}_{0}}{} \text {; } \tag{23}
\end{equation*}
$$

where $c_{s}$ denotes the sound speed of the baryon－photon plasm a，which is $1 \stackrel{p}{3}$ before recombination．The stochasticly averaged solution ofeq．（23）is 0()$={ }^{R}{ }_{\text {en }} \mathrm{kcs}_{\mathrm{s}} \mathrm{d}^{0}+\quad \mathrm{o}(\mathrm{en})$ ， where en denotes the tim e when the m ode k enters the horizon，and $\mathrm{o}(\mathrm{en})$ is the initial phase．The position of the D oppler peaks for adiabatic perturbations is approxim ately determ ined by a phase relation $0($ re $)=n$ ，where $n$ is integer．Eq．（23）show s also that the phase uctuation due to $R_{0}$ in the period from en to $r e$ is

$$
\begin{equation*}
0^{\prime}{\underset{\text { en }}{\text { re }}}_{\mathrm{Z}}^{\mathrm{o}} \frac{1}{2 \mathrm{~h} \mathrm{oi}_{0} \frac{1}{\mathrm{kc}_{s}} \frac{\mathrm{dR}_{0}\left({ }^{0}\right)}{\mathrm{d}^{0}}: ~} \tag{24}
\end{equation*}
$$

Generally，the term $R_{1}$ leads to a phase uctuation at least of

$$
\begin{equation*}
{ }_{1}{ }^{Z}{ }_{\text {en }}^{\text {re }} d^{0} \frac{1}{2 h ~_{1} i k c_{s}} \frac{1}{d R_{1}\left({ }^{0}\right)} d^{0}: \tag{25}
\end{equation*}
$$

C onsidering that the derivative $\left(1=k c_{s}\right) d=d$ in eq.(25) contributes a factor of order 1 , and using eqs. (10), (15) and (17), one obtains the $m$ ean phase uctuation as

The factor $(T=T)^{2}=h j \quad 1(; k){ }^{2} i$ is no less than 1 , and therefore, the RM $S$ of the phase uctuation can be estim ated as

$$
\begin{equation*}
\mathrm{q} \overline{\mathrm{~h}(\quad 1)^{2} \mathrm{i}} \quad 1: 8 \quad 10^{3^{\mathrm{q}}} \overline{(2 l+1) \mathrm{N}_{\mathrm{c}}} \tag{27}
\end{equation*}
$$

where $\mathrm{N}_{\mathrm{c}} \quad$ (re en) is the m ean num ber of collisions in the entire period of subhorizon evolutions of $m$ ode $k$ before the recom bination. Therefore, the behavior of the stochastic uctuation of the phase for the l-oscillation is just like a B row nian drifting: the num ber of collisions corresponds to the num ber ofsteps in the random walk, and them ean shift per step is about 1:8 $10^{3}{ }^{\mathrm{P}} \overline{2 l+1}$. ForD oppler peaks, we havel 100 , and $N \quad$ fe en $) \quad 10^{3}$. Therefore, we conclude that the RMS of the Brownian phase drifting due to Thom son scattering is order 1, signi cant enough to disturb the coherence.

In addition to the Thom son scattering, there are other stochastic foroes in the baryonphoton plasm a, such as non-T hom son term s ofthe C om pton scattering, the stochastic term s in the hydrodynam ical equation of baryons. F luctuations from di erent souroes $m$ ostly are additive. O ur estim ation on the phases drifting is thus a conservative one. The proposed D oppler peaks in the CM B angular pow er spectrum probably do not exist. D i erent causal areas at the recom bination can be considered as independent realizations of the stochastic force. The dispersion of the currently observed CM B anisotropies on angular scale of one degree is consistent w ith the soenario of the B row nian drift of the phases.
