Abstract.

W ith attempts to quench the cosm ological constant having so far failed, we instead investigate what could be done if is not quenched and actually gets to be as big as elementary particle physics suggests. Since the quantity relevant to cosm ology is actually , quenching it to its sm allmeasured value is equally achievable by quenching not but G instead, with the G relevant to cosm ology then being much sm aller than that measured in a low energy C avendish experiment. A gravitationalm odel in which this explicitly takes place, viz. conform al gravity, is presented, with the model being found to provide for a completely natural, non ne tuned accounting of the recent high z accelerating universe supernovae data, no matter how big itself actually gets to be. Thus to solve the cosm ological constant problem we do not need to change or quench the energy content of the universe, but rather only its e ect on cosm ic evolution.

The recent discovery [1,2] that the current era deceleration parameter $q(t_0)$ 1=2 has made the already extremely disturbing cosm obgical conis close to stant problem even more vexing than before. Speci cally, with $q(t_0)$ being given in standard gravity by $q(t_0) = (n=2)$ 1) M (t₀) (t_0) [where м (t) = 8 G M (t)=3c²H² (t) is due to ordinary matter (i.e. matter for which M (t) = 4), and where $A = R^{n}$ (t) where A > 0 and 3 n $(t) = 8 G = 3cH^{2}(t)$ is due to a cosm ological constant], we see that not only must c be non-zero, it must be of order $3c^2H^2$ (t₀)=8 G = _C (t₀) in m agnitude, i.e. it must be quenched by no less than 60 orders of magnitude below its natural value as expected from fundamental particle physics. Additionally, since such a quenched c would then be of order $M(t_0)$ as well (the so-called cosm ic coincidence), our particular cosm ological epoch would then only be achievable in standard gravity if the macroscopic Friedm ann evolution equation were to be ne-tuned at very early times to incredible precision. Any still to be found fundam entalm icroscopic physics mechanism which m ight in fact quench c by the requisite sixty orders of m agnitude would thus still. leave standard gravity with an additional macroscopic coincidence to explain.

¹⁾ astro-ph/9901219 v2, February 26, 2001.

Since no mechanism has yet been found which might actually quench c and since its quenching might not necessarily work macroscopically anyway, we shall thus turn the problem around and ask what can be done if c is not in fact quenched and is in fact as big as elementary particle physics suggests. To this end we note immediately that it would still be possible to have $q(t_0)$ be of order one today (the measurable consequence of c) if instead of quenching c we instead quench G, with the cosm obgical G then being replaced by an altogether smaller G_{eff} . Since observationally $_M(t_0)$ is known to not be bigger than $_C(t_0)$, any successful such cosm obgical quenching of G (successful in the sense that such relativistic quenching not modify standard non-relativistic physics) would immediately leave us with a non-quenched c which would then not su er from any cosm ic coincidence problem.

G iven these remarks it is thus of interest to note that it is precisely a situation such as this which obtains in the conform algravity theory which has recently been advanced [3{9] as a candidate alternative to the standard gravitational theory. C onform algravity is a fully covariant gravitational theory which, unlike standard gravity, possesses an additional local scale invariance, a symmetry which when unbroken sets any fundam ental cosm obgical constant and any fundam ental G to zero [3]. U nlike standard gravity conform algravity thus has a great deal of control over the cosm obgical constant, a control which is found to be of relevance even after the conform al symmetry is spontaneously broken by the non-vanishing of a scalar eld vacuum expectation value S₀ below a typical critical tem perature T_V. In fact in the presence of such breaking the standard attractive G phenom enology is found to still emerge at low energies [5], while cosm ology is found [4] to instead be controlled by the elective G eff = $3d^2=4$ hS₀², a quantity which by being negative immediately entails cosm ic repulsion [7], and which, due to its behaving as $1=S_0^2$, is made small by the very same mechanism which serves to make itself large.

O ther than the use of a changed G the cosm ic evolution of conform algravity is otherwise the same as that of the standard one, viz. $[7\{9\}]$

$$R^{2}(t) + kc^{2} = 3d^{2}R^{2}(t) (M(t) + (t)) = 4 hS_{0}^{2}G R^{2}(t) (M(t) + (t))$$
$$q(t) = (n=2 1)M(t) (t) (t) (1)$$

(Eq. (1) serves to de ne $_{\rm M}$ (t) and (t)). Moreover, unlike the situation in the standard theory where values for the relevant evolution parameters (such as the sign of) are only determined phenom enologically, in conform algravity essentially everything is already a priori known. With conform algravity not needing dark matter to account for non-relativistic issues such as galactic rotation curve system atics [6], $_{\rm M}$ (t₀) can be determined directly from luminous matter alone, with galaxy luminosity accounts giving a value for it of order 0.01 $_{\rm C}$ (t₀) or so. Further, with c being generated by vacuum breaking in an otherwise scaleless theory, since such breaking lowers the energy density, c is unambiguously negative, with it thus being typically given by $T_{\rm V}^4$. Then with G eff also being negative, (t) is necessarily positive, just as needed to give cosm ic acceleration. Similarly, the sign of the

spatial 3-curvature k is known from theory [9] to be negative,² som ething which has been independently con rm ed from a study of galactic rotation curves [6]. Finally, since G_{eff} is negative, the cosm ology is singularity free and thus expands from a nite maximum temperature T_{max} , a temperature which for k < 0 is necessarily

greater than T_v [7{9] (so that a large T_v entails an even larger T_{max}).

G iven only that , k and G $_{\rm eff}$ are all negative, the tem perature evolution of the theory is then completely determ ined for arbitrary $T_{m\,ax}$ and T_{v} , to yield [7{9]

(t) =
$$(1 \quad T^2 = T_{max}^2)^{-1} (1 + T^2 T_{max}^2 = T_V^4)^{-1}; \quad M(t) = (T^4 = T_V^4) \quad (t) \quad (2)$$

at any T. Thus, from Eq. (2) we see that $\sin p \ln p \sec T_{max}$ $T(t_0)$, i.e. simply because the universe is as old as it is, it im mediately follows that (t_0) has to lie som ewhere between zero and one today no matter how big (or small) T_v might be. T (t₀), M (t₀) has to be completely negligible,³ so that $q(t_0)$ must Then, since T_v thus necessarily lie between zero and m inus one today notwithstanding that T_V is huge.M oreover, the larger T_v gets to be, the m ore (t₀) will be reduced below one, with it taking a value close to one half should T (t₀) $T_{max}=T_v^2$ be close to one.W ith (t_0) is therefore given as $1 + kc^2 = R^2(t_0)$, a quantity $_{\rm M}$ (t₀) being negligible today, which necessarily lies below one if k is negative. Thus in a k < 0 conform algravity universe, once the universe has cooled enough, (t) will then be forced to have to lie between zero and one no matter how big may ormay not be. The contribution of to cosm ology is thus seen to be completely under control in conform algravity, with the theory thus leading us right into the (t_0) ' 1=2, _M $(t_0) = 0$ region, a region which, while foreign to standard gravity, is nonetheless still fully compatible with the reported supernovae data ts. Hence to solve the cosm ological constant problem we do not need to change or quench the energy content of the universe, but rather only its e ect on cosm ic evolution. ²⁾ At the highest tem peratures the zero energy density required of a (then) completely conform al invariant universe is maintained by a cancellation between the positive energy density of ordinary matter and the negative energy density due to the negative curvature of the gravitational eld.

 $_{\rm M}$ (t₀) is suppressed by G _{eff} being sm all, and not by $_{\rm M}$ (t₀) itself being sm all.
