(April 14, 2024)

U sing coherent-potential to describe disorder, G aspari-G yor y approach to evaluate electronphonon coupling, and A llen-D ynes equation to calculate T_c , we show that in M $g_1 \ _xM \ _xB_2$ (M A l;LiorZn) alloys (i) the way T_c changes depends on the location of the added/m odi ed k-resolved states on the Ferm i surface and (ii) the variation of T_c as a function of concentration is dictated by the B p D O S. In addition, using full-potential calculations for M gM B₄, we show that (i) at x = 0.5 a superstructure can form in M $g_1 \ _xA \ _xB_2$ but not in M $g_1 \ _xLi_xB_2$ or M $g_1 \ _xZn_xB_2$, and (ii) B layer shifts towards the in purity layer, m ore for A l than for LiorZn.

PACS numbers: 74.25 Jb, 74.70 Ad

Since the discovery of superconductivity in M gB₂ [1] the experimental $[1\{6\}]$ and theoretical $[7\{16\}]$ e orts have greatly in proved our understanding of the nature of interaction responsible for superconductivity (SC) in M qB₂: It has become clear that almost all facets of the phonon-m ediated electron-electron interaction have a dram atic in uence over the superconducting behavior of M gB₂: For example, the electron-phonon m atrix elements change considerably as one moves away from the cylindrical Ferm i sheets along to A [9,16], anharm onic e ects [6,15] have to be included in the dynam icalm atrix [16], and nally k-dependent fully an isotropic E liashberg equations have to be solved [16] for a complete and accurate description of the superconducting properties of M gB₂:Such a strong dependence of the superconducting properties of M gB_2 on di erent aspects of the interaction has opened up the possibility of dram atically modifying its superconducting behavior by changing the interaction in various ways and thereby learning more about the interaction itself. A lloying M gB₂ with various elements and then studying their SC properties o ers such an opportunity.

There have been several studies of changes in the SC properties of M gB₂ upon substitutions of various elements such as Be; Li; C; Al; N a; Zn; Zr; Fe; Co; N i; and others [5,17{20}]. The main e ects of alloying are seen to be (i) a decrease in transition temperature, T_c, with increasing concentration of the alloying elements although the rate at which the T_c changes depends on the element being substituted, (ii) a slight increase in the T_c in case of Zn [19,20] substitution while for Si and Li the T_c remains essentially the same, (iii) persistence of superconductivity up to x 0:7 in M g_{1 x} A l_xB₂ [5,17], (iv) a change in crystal structure and the form ation of a superstructure at x = 0:5 in M g_{1 x} A l_xB₂ [17], and (v) a change in the lattice parameters a and c:

In an e ort to understand the changes in the electronic structure and the superconducting properties of M gB₂ alloys, we have carried out ab initio studies of M g_{1 x} A l_x B₂; M g_{1 x} L i_x B₂ and M g_{1 x} Z n_xB₂ al-

loys. We have used K orringa-K ohn-R ostoker coherentpotential approximation [21,22] in the atom ic-sphere approximation (K K R-A SA C PA) method for taking into account the electron-ghonon coupling constant , and A llen-D ynes equation [24] for calculating T_c in M $g_1 \ x A l_x B_2$; M $g_1 \ x L i_x B_2$ and M $g_1 \ x Z n_x B_2$ alloys as a function of A l; L i and Z n concentrations, respectively. W e have analyzed our results in terms of the changes in the spectral function [22] along to A evaluated at the Ferm i energy, E_F , and the total density of states (D O S), in particular the changes in the B p contribution to the total D O S, as a function of concentration x.

For exam ining the possibility of superstructure form ation at x = 0.5; we have used ABINIT code [25], based on psuedopotentials and plane waves to optimize the cell parameters a and c as well as relax the cell-internal atom ic positions of M gAlB₄; M gL iB₄ and M gZ nB₄ in P 6=m m m structures. We have used these atom ic positions to carry out a total energy comparison using KKR-ASA CPA between the ordered and the substitutionally disordered M g_{1 x} A l_x B₂; M g_{1 x} L i_x B₂ and M g_{1 x} Z n_xB₂ alloys at x = 0.5. Such an approach allow s us to check the possibility of form ation of a layered or a m ixed superstructure at x = 0.5 in these alloys. Before we describe our results, we outline some of the computational details.

The charge self-consistent electronic structure of M $g_1 \times A l_x B_2$; M $g_1 \times L i_x B_2$ and M $g_1 \times Z n_x B_2$ alloys as a function of x has been calculated using the KKR-ASA CPA method. We have used the CPA rather than a rigid-band m odel because CPA has been found to reliably describe the e ects of disorder in metallic alloys [21,22]. We parametrized the exchange-correlation potential as suggested by Perdew-W ang [26] within the generalized gradient approximation. The Brillouin zone (BZ) integration was carried out using 1215 k points in the irreducible part of the BZ. For DOS and spectral function calculations, we added a small imaginary component of 1 m Ry and 2 m Ry, respectively, to the energy

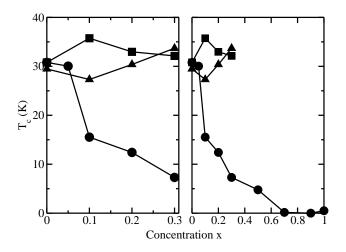

FIG.1. The calculated variation of T_c as a function of concentration x in M g_1 _xA l_xB_2 , M g_1 _xL i_xB_2 and M g_1 _xZ n_xB_2 alloys.

and used 4900 k-points in the irreducible part of the BZ. The lattice constants for M $g_1 \ _x A \ _x B_2$; M $g_1 \ _x L \ _x B_2$ and M $g_1 \ _x Z \ n_x B_2$ alloys as a function of x were taken from experiments [17{19]. The W igner-Seitz radii for M g, A l and Z n were slightly larger than that of B. The sphere overlap which is crucial in ASA, was less than 10% and the m axim um l used was $l_{max} = 3$.

The electron-phonon coupling constant was calculated using Gaspari-Gyor y [23] formalism with the charge self-consistent potentials of M $g_{1 x} A l_x B_2$; M $g_{1 x} L i_x B_2$ and M $g_{1 x} Z n_x B_2$ obtained with the KKR-ASA CPA method. Subsequently, the variation of T_c as a function of A l, Li and Z n concentrations was calculated using A llen-D ynes equation [24]. The average values of phonon frequencies ! In for M gB₂ and A IB₂ were taken from Refs. [9,10] respectively. For interm ediate concentrations, we took ! In to be the concentration-weighted average of M gB₂ and A IB₂. For M g1 x L i_x B₂ and M g1 x Z n_x B₂ we used the same value of ! In as that for M gB₂.

The structural relaxation of M gALB₄; M gLiB₄ and M gZnB₄ was carried out by the molecular dynam – ics program ABINIT with Broyden-Fletcher-Goldfarb-Shanno minimization technique [25] using Troullier-M artins psuedopotentials [27], 512 M onkhorst-Pack [28] k-points and Teter parameterization [25] for exchangecorrelation. The kinetic energy cuto for the plane waves was 110 Ry.

Based on our calculations, described below, we nd that in M $g_1 \ _x A \ l_x B_2$; M $g_1 \ _x L \ i_x B_2$ and M $g_1 \ _x Z \ n_x B_2$ alloys (i) the way T_c changes depends on the location of the added/m odi ed k-resolved states on the Ferm i surface, (ii) the variation of T_c as a function of concentration

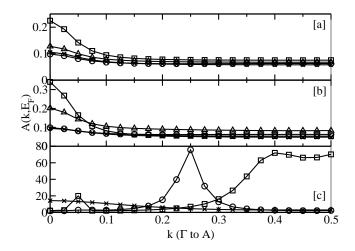

FIG.2. The calculated spectral function along to A, evaluated at the Ferm ienergy, as a function of concentration x in M $g_1 \ _xA \ _kB_2$, M $g_1 \ _xLi_xB_2$ and M $g_1 \ _xZn_xB_2$ alloys. Figures (a) and (b) correspond to x = 0.1 and x = 0.3, respectively and the symbols open circle, open square, x and open triangle correspond to M gB_2 , M $g_1 \ _xA \ _kB_2$, M $g_1 \ _xLi_xB_2$ and M $g_1 \ _xZn_xB_2$ alloys respectively. In gure (c) the symbols open circle, open square and x correspond to A B_2 , M $g_{0:1}A \ _{0:9}B_2$ and M $g_{0:4}A \ _{0:6}B_2$, respectively. For clarity, in gure (c) we have multiplied the spectral function of M $g_{0:4}A \ _{0:6}B_2$ by 100.

is dictated by the B p contribution to the totalDOS, (iii) at x = 0.5 a superstructure can form in M $g_1 \times A l_x B_2$ but not in M $g_1 \times L i_x B_2$ or M $g_1 \times Z n_x B_2$, and (iv) B layer shifts towards the in purity layer, more for Althan for LiorZn:

The main results of our calculations are shown in Fig. 1, where we have plotted the variation in T_c of M $g_1 \ge A \ge B_2$; M $g_1 \ge Li_x B_2$ and M $g_1 \ge Z n_x B_2$ alloys as a function of concentration x. The calculations were carried out as described earlier with the same value of

= 0:09 for all the concentrations. The T_c for M gB₂ is equal to 30:8K; which is consistent with the results of other works [7,9,10] with sim ilar approxim ations. The corresponding is equal to 0:69: For 0 < x0:3, the T_c increases slightly for M $g_1 \times Li_x B_2$ and M $g_1 \times Zn_x B_2$, while it decreases substantially for M $g_1 \times A_x B_2$; as is found experimentally [5,17]. Note that for x = 0:1; our calculation shows M $g_{1 x} L i_x B_2$ to have a T_c higher than that of M $g_{1 x} Z n_x B_2$ by about 7K [18{20]. In Fig.1 (right panel) we have shown the variation in $\rm T_{\rm c}$ in M $g_{1 x} A l_x B_2$ alloys as a function of concentration for 0 Х 1: As a function of Al concentration, the T_c decrease rapidly from 30 K at x = 0.05 to about 15 K at x = 0:1: The T_c decreases slow ly between x = 0:4 and x = 0.5: At x = 0.7 the T_c vanishes and remains essen-

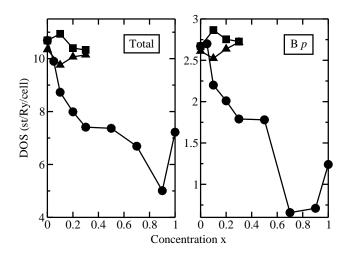

FIG.3. The calculated total density of states at the Ferm i energy (left panel) and the B p contribution to the total DOS (right panel) in M $g_1 \ _xA \ _xB_2$, M $g_1 \ _xL \ _xB_2$ and M $g_1 \ _xZ \ n_xB_2$ alloys.

tially zero thereafter. The calculated variation in T_c , as shown in Fig. 1, is in very good qualitative agreement with the experiments [5].

In order to understand the variation of T_c in $M g_{1 x} A l_{x} B_{2}; M g_{1 x} L i_{x} B_{2}$ and $M g_{1 x} Z n_{x} B_{2}$ alloys as a function of concentration x, we have analyzed our results in terms of the spectral functions, the contribution of B oron p-electrons to the total D O S and the total DOS. In Fig. 2(a)-(c), we show the spectral functions along to A direction evaluated at E_F in M $g_{1x} A l_x B_2$; $M g_{1 x} L i_x B_2$ and $M g_{1 x} Z n_x B_2$ alloys for x = 0:1 (Fig. 2(a), x = 0.3 (Fig.2(b)), and x = 0.6 1.0 (Fig. 2(c)). From Figs. 2(a)-(b) it is clear that the substitution of A l in M gB₂ leads to creation of m ore new states along to A direction than the substitution of Z n or Li: Since the hole-like cylindrical Ferm i sheet along to A contributes much more to the electron-phonon coupling [16], the creation of new electron states along to A direction weakens considerably the overall coupling constant ; which, in turn, reduces the T_c m ore in M $g_1 \times A_x B_2$ than in either M $g_{1 x} Z n_x B_2$ or M $g_{1 x} L i_x B_2$. Thus, in our opinion, the way T_c changes in M gB $_2$ upon alloying depends dram atically on the location of the added/m odi ed kresolved states on the Ferm i surface.

Having explained the di erences in behavior of M gB₂ upon alloying with Al; Li and Zn; we now try to understand the changes in their properties as a function of concentration x: In Fig. 3(a)-(b) we have shown the total DOS at E_F (Fig. 3(a)) and the B p contribution to the total DOS at E_F (Fig. 3(b)) in M g_{1 x} Al_xB₂; M g_{1 x} Li_xB₂ and M g_{1 x} Zn_xB₂ alloys as a function of concentration x:W e nd that as a function of concentration.

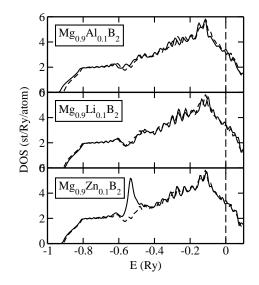

FIG.4. The calculated total density of states (solid line) for M $g_{0:9}A \downarrow_{0:1}B_2$ (upperpanel), M $g_{0:9}L \downarrow_{0:1}B_2$ (m iddle panel) and M $g_{0:9}Z n_{0:1}B_2$ (lower panel) alloys. For comparison the total DOS for M gB₂ (dashed line) is also shown. The dashed vertical line indicates the Ferm i energy.

tion, the variation in $T_{\rm c}$, as shown in Fig.1, follow sclowely the behavior of the total DOS at $E_{\rm F}$ and in particular the variation in B p contribution to the total DOS at $E_{\rm F}$. It is also not surprising to see that the vanishing of superconductivity in M $g_{1 \ x}$ A l_x B $_2$ at x 0:7 coincides with a very sm all B p contribution to the total DOS.

In Fig. 4(a)-(c) we show the total DOS of M $g_1 \times A_k B_2$, M $g_1 \times Li_x B_2$ and M $g_1 \times Zn_x B_2$ alloys, respectively, at x = 0.1: In the same plot we also show the total DOS of M gB_2 obtained using the same approach. The overall downward (upward) movement of the total DOS in M $g_{0:9}A_{0:1}B_2$ (M $g_{0:9}Li_{0:1}B_2$) with respect to that of M gB_2 is due to the addition (rem oval) of electrons. In Fig. 4(c), the peak in the total DOS at around 0.53 R y below E_F is due to the 3d states of Z n:

F inally, we discuss the possibility of superstructure formation at x = 0.5. In Table I we show the optimized cell param eters as well as the cell-internal relaxations for M gAlB₄; M gLiB₄ and M gZ nB₄ calculated using the ABINIT program. We nd that the Boron layer shifts signi cantly more towards Al layer in M gA lB₄ than towards either Li or Zn layer in MgLiB₄ or MgZnB₄, respectively. The shift of B layer by 0:24 a.u: towards Allayer in M qA B₄ compares well with the corresponding shift obtained in Ref. [29]. However, the shift of B layer towards Li and Zn layers in M gLiB₄ and M gZ nB₄ respectively implies that it is not simply due to the extra positive charge on the impurity layer, as suggested in Ref. [29] in the case of M $qA \square_4$: In Table I we have also listed the calculated ordering energy, E_{ord} ; which is the di erence between the total energies of the

TABLE I. The calculated lattice constants a and c=a, the shift of the B layer along the c-axis towards the impurity layer, and the ordering energy $E_{\rm ord}$ at x = 0.5. The lattice constant a and the shift are in atom ic units while $E_{\rm ord}$ is in mRy=atom.

A lloy	a	c=a		E _{ord}
M gAlB ₄	5.799	2,242	0.24	-12.1
MgLiB ₄	5.685	2,287	0.04	+ 4.8
M gZ nB $_4$	5.789	2.254	80.0	+12

ordered M gA lB₄, M gL iB₄ and M gZ nB₄ and the corresponding disordered M $g_{0:5}A l_{0:5}B_2$; M $g_{0:5}L i_{0:5}B_2$ and M $g_{0:5}Z n_{0:5}B_2$ alloys, obtained using KKR-ASA CPA m ethod. It clearly shows the possibility of form ation of a superstructure in M $g_{0:5}A l_{0:5}B_2$ because the fully-relaxed M gA lB₄ is lower in energy by 12m Ry=atom in comparison to the disordered M $g_{0:5}A l_{0:5}B_2$: How ever, within the limitations of our approach, we nd that M $g_{0:5}L i_{0:5}B_2$ and M $g_{0:5}Z n_{0:5}B_2$ are unlikely to form superstructures since E_{ord} is positive in these two cases. O ur results also show that a structure m ade up of layers consisting of a random mixing of M g and A l atom s and described by CPA, is higher in energy than a structure m ade up of alternate layers of M g and A l atom s [29].

In conclusion, we have shown that in M g_{1 x} A l_xB₂; M g_{1 x} L i_xB₂ and M g_{1 x} Z n_xB₂ alloys (i) the way T_c changes depends on the location of the added/m odi ed k-resolved states on the Ferm i surface, (ii) the variation of T_c as a function of concentration is dictated by the B p contribution to the totalDOS at E_F, (iii) at x = 0.5 a superstructure can form in M g_{1 x} A l_xB₂ but not in M g_{1 x} L i_xB₂ or M g_{1 x} Z n_xB₂, and (iv) B layer shifts towards the in purity layer, more for Al than for Li or Z n:
