We present a calculation of the quasiparticle contribution to the longitudinal thermal conductivities $\kappa_{xx}(H;T)$ (perpendicular to the external field) and $\kappa_{zz}(H;T)$ (parallel to the external field) as well as the transverse (Hall) thermal conductivity $\kappa_{xy}(H;T)$ of an extreme type-II superconductor in a high magnetic field ($H_{c1} < H < H_{c2}$) and at low temperatures. In the limit of frequency and temperature approaching zero ($\omega \rightarrow 0, T \rightarrow 0$), both longitudinal and transverse conductivities upon entering the superconducting state undergo a reduction from their respective normal state values by the factor $(\gamma)^2$, which measures the size of the region at the Fermi surface containing gapless quasiparticle excitations. We use our theory to numerically compute the longitudinal transport coefficient in borocarbide and A-15 superconductors. The agreement with recent experimental data on $\text{LuNi}_2\text{B}_2\text{C}$ is very good.

I. INTRODUCTION

The low-temperature, high-field region in the H - T phase diagram of an extreme type-II superconductor is the regime where the Landau level quantization of the electronic energies within the superconducting state is well defined, i.e. the cyclotron energy $\hbar\omega_c > k_B T$, where $(k_B T)$ is the BCS gap, T is the temperature and (Γ) is the scattering rate due to disorder. This regime should be contrasted with the more familiar opposite limit of low magnetic fields and high temperatures where electrons occupy a huge number of Landau levels and where the temperature and/or impurity scattering broaden these levels and reduce the significance of Landau quantization. With the Landau level structure fully accounted for one discovers a qualitatively new nature of quasiparticle excitations at high fields: for fields H below but near H_{c2} the quasiparticle spectrum is gapless at a discrete set of points on the Fermi surface. These gapless excitations reflect a coherent quasiparticle propagation over many unit cells of a closely packed vortex lattice with fully overlapping vortex cores^{1,2,3}. The presence of such low-lying excitations makes an s -wave, "conventional" superconductor in a high magnetic field somewhat similar to an anisotropic, "unconventional" superconductor with nodes in the gap. In the low-temperature and high-field regime however, the nodes in the gap reflect the center-of-mass motion of the Cooper pairs in the magnetic field, in contrast to d -wave superconducting cuprates where such nodes are due to the relative orbital motion. This gapless behavior in bulk systems is found to persist to surprisingly low magnetic fields $H \approx 0.2 - 0.5 H_{c2}$. Below H_{c2} the gaps start opening up in the quasiparticle spectrum and the system eventually reaches the low-field regime of localized states in the cores of isolated, well-separated vortices³. At the present

time the strongest evidence for the quantization of quasiparticle orbits within the superconducting state comes from observations of the de Haas-van Alphen (dHvA) oscillations in various superconducting materials⁴. The persistence of the dHvA signal deep within the mixed state, with the frequency of oscillations still maintaining the normal state value, can be attributed to the presence of a small portion of the Fermi surface containing gapless quasiparticle excitations, surrounded by regions where the gap is large^{5,6}.

Another useful probe of low-energy excitations in superconductors is measurement of their thermal transport. The simultaneous measurements of the field dependent longitudinal $\kappa_{xx}(H;T)$ and transverse $\kappa_{xy}(H;T)$ thermal conductivities are now feasible experimentally and can yield information on both quasiparticle dynamics and the pairing mechanism. The dependence of transport coefficients on magnetic field is currently a hotly debated issue in the scientific community in light of the experimental observation of field independent plateaus in the longitudinal thermal conductivity of high temperature superconductors (HTS) at low fields ($H_{c1} < H < H_{c2}$)⁷. The field-independent κ_{xx} is attributed to the $d_{x^2-y^2}$ pairing mechanism at low fields and to the nodal structure of the resulting quasiparticle excitations^{8,9}. The presence of propagating gapless quasiparticles in the superconducting state at low temperatures and high magnetic fields should also lead to transport properties qualitatively different from those found in s -wave superconductors at low fields, where the number of thermally activated quasiparticles is exponentially small and the only contribution to the thermal conduction is found along the field direction and originates from the bound states within vortex cores. Recently, the thermal conductivity of the borocarbide superconductor $\text{LuNi}_2\text{B}_2\text{C}$ was measured down to $T = 70$ mK by Boaknin et al.¹⁰ in a magnetic field perpendicular to the heat current from $H = 0$ to above $H_{c2} = 7$ Tesla.

In the limit of $T \rightarrow 0$, a considerable thermal transport was observed in the mixed state of the superconductor ($H_{c1} < H < H_{c2}$), indicating the presence of delocalized low-energy excitations at the Fermi surface. On the other hand, no thermal transport was observed at zero field, a result consistent with the s-wave superconducting gap without nodes at the Fermi surface.

The purpose of this work is to examine the contribution of low-energy quasiparticles to the thermal transport of conventional, i.e. extreme type-II superconductors in the regime of high magnetic fields and low temperatures. The paper is organized as follows: In Sec. II we develop the Kubo formalism for the transport coefficients within the Landau level pairing mechanism while in Sec. III we incorporate disorder in the Green's function description of a three-dimensional superconductor in a high magnetic field. We use the formalism of Sec. II and III in Sec. IV to examine both longitudinal $\sigma_{xx}(H;T)$ and $\sigma_{zz}(H;T)$ as well as transverse $\sigma_{xy}(H;T)$ conductivities in the regime of the frequency $\omega \rightarrow 0$ and the temperature $T \rightarrow 0$. Finally, in Sec. V we report on numerical calculations of the thermal transport in the borocarbide $\text{LuNi}_2\text{B}_2\text{C}$ and the A-15 superconductor V_3Si and compare our theoretical plots with the available experimental data.

II. KUBO FORMALISM IN THE LANDAU LEVEL PAIRING SCHEME

Thermal conductivities can be calculated within the framework of the Kubo formalism as a linear response of a system to an external perturbation¹¹

$$\frac{\sigma_{ij}(\omega;T)}{T} = \frac{1}{T^2} \text{Im} \frac{\chi_{ij}^{\text{ret}}(\omega)}{\omega} \quad (1)$$

where $\chi_{ij}^{\text{ret}}(\omega) = \chi_{ij}(i\omega \rightarrow +i)$ and

$$\chi_{ij}(i\omega) = \int_Z d^3x_1 d^3x_2 \chi_{ij}(1;2;i\omega);$$

$$\chi_{ij}(1;2;i\omega) = \int_0^\infty dt e^{i\omega t} \langle T \hat{j}_i(\mathbf{x}_1;1) \hat{j}_j(\mathbf{x}_2;0) \rangle \quad (2)$$

is the spatially averaged, finite temperature thermal current-current correlation function tensor and $1=k_B T$. In order to derive the heat current operators $j(1)$ and $j(2)$ at the space-time point $1 = (\mathbf{x}_1;1)$ and $2 = (\mathbf{x}_2;0)$ we follow the standard s-wave derivation in zero field¹² and generalize it to our case of a non-uniform

gap at high fields. A similar approach was recently utilized in Ref. 9 for a d-wave superconductor in zero field. The heat current carried by the quasiparticles can be computed within the standard variational procedure as

$$\mathbf{j} = \frac{\partial L}{\partial (\nabla \psi)} + \frac{\partial L}{\partial (\nabla \bar{\psi})} \quad (3)$$

from the Lagrangian density

$$L = \frac{1}{2m} \nabla \psi^\dagger \cdot \nabla \psi + \frac{e}{2m c i} (\psi^\dagger \nabla \psi - \nabla \psi^\dagger \cdot \psi) \cdot \mathbf{A} + \frac{e^2}{2m c^2} \mathbf{A}^2 \psi^\dagger \psi - \frac{1}{2i} (\psi^\dagger \nabla^2 \psi - \nabla^2 \psi^\dagger \cdot \psi) - \frac{1}{2} g \psi^\dagger \psi \quad (4)$$

where all the energies are measured with respect to the chemical potential and $\psi = \psi e^{-i\mu t}$. The Nambu's two-component field operators $\psi(\mathbf{r})$ are written in a compact notation for the sake of brevity. In extreme type-II superconductors, as soon as the magnetic field satisfies $H > H_{c1}(T)$ the vector potential $\mathbf{A}(\mathbf{r})$ can be safely assumed to be entirely due to the external field $\mathbf{H} = r \mathbf{A}$. This holds over most of the $H-T$ phase diagram. We have used a simple BCS model point interaction $V(\mathbf{r}_1, \mathbf{r}_2) = -g \delta(\mathbf{r}_1 - \mathbf{r}_2)$ in expression (4). To lowest order in the concentration of impurities, the electron-impurity interaction can be omitted in computing the heat current. The effect of disorder will be included later in the Green's functions for a superconductor. The variational procedure (3) yields

$$j(1) = \frac{1}{2m} \frac{\partial}{\partial \psi_1} (\psi^\dagger_0 - \frac{e\mathbf{A}}{ci} \psi_0) + \frac{\partial}{\partial \psi_1} (\psi^\dagger_0 + \frac{e\mathbf{A}}{ci} \psi_0) \psi_1(1^0) \quad (1) j_{i=1} \quad (5)$$

for the heat current operator. With this definition it is straightforward to calculate the correlation tensor $\chi_{ij}(1;2;i\omega)$ within the usual Hartree-Fock approximation (i.e., bare bubble approximation) defined by

$$\langle T \hat{j}_i(1) \hat{j}_k(2) \rangle = \frac{1}{i} \langle \hat{j}_i(1^0) \hat{j}_k(2^0) \rangle = -G_{ii}(1;2^0) G_{kk}(2;1^0) \quad (6)$$

where G_{kl} is the Nambu's matrix Green's function. Inserting (5) into (2) and with the help of (6) the current-current correlator becomes

$$\chi_{ij}(1;2;i\omega) = \frac{1}{4m^2} \text{Tr} \left[\left(i(\nabla_1 + \nabla_2) \left(\psi^\dagger_0 - \frac{e\mathbf{A}}{ci} \psi_0 \right) + i(\nabla_1 - \nabla_2) \left(\psi^\dagger_0 + \frac{e\mathbf{A}}{ci} \psi_0 \right) \right) \right. \\ \left. i(\nabla_2 + \nabla_1) \left(\psi^\dagger_0 + \frac{e\mathbf{A}}{ci} \psi_0 \right) - i(\nabla_2 - \nabla_1) \left(\psi^\dagger_0 - \frac{e\mathbf{A}}{ci} \psi_0 \right) \right] G_{ii}(1;2^0) G_{jj}(2;1^0) \quad (7)$$

where σ_3 is a Pauli matrix, $\omega_m = 2\pi m / \tau$ are bosonic Matsubara frequencies and $\mathbf{r} = (x, y)$.

It was shown in Ref. 1 that the mean-field Hamiltonian corresponding to the Lagrangian density (4) can be diagonalized in terms of the basis functions of the Magnetic

Sublattice Representation (MSR), characterized by the quasimomentum $\mathbf{q}$ perpendicular to the direction of the magnetic field. The eigenfunctions of this representation in the Landau gauge $\mathbf{A} = H(-y; 0; 0)$ and belonging to the m -th Landau level, are

$$\psi_{k_z, q; m}(\mathbf{r}) = \frac{1}{2^n n!} \frac{b_y}{L_x L_y L_z} \exp(i k_z z) \exp\left(-\frac{b_x}{2a} k^2 - i k q b_y\right) \exp\left[i\left(q_x + \frac{k}{a}\right)x - \frac{1}{2}\left(y + \frac{k}{a}\right)^2\right] H_m\left(\frac{y}{a} + \left(q_x + \frac{k}{a}\right)\right); \quad (8)$$

where $\mathbf{r}$ is the spatial coordinate and k_z is the momentum along the field direction, $a = (a; 0)$ and $b = (0; b_y)$ are the unit vectors of the triangular vortex lattice, $l = \hbar c / e H$ is the magnetic length and $L_x L_y L_z$ is the volume of the system. $H_m(x)$ is the Hermite polynomial of order m . Quasimomenta $\mathbf{q}$ are restricted to the first Magnetic Brillouin Zone (MBZ) spanned by vectors $\mathbf{Q}_1 = (b_y l^2; b_x l^2)$ and $\mathbf{Q}_2 = (0; 2a l^2)$.

Normal and anomalous Green's functions for a clean superconductor in this representation can be constructed as

$$G_{11}(\mathbf{r}; \mathbf{r}'; !) = \sum_{n, \mathbf{k}_z, \mathbf{q}} (1)_{n, \mathbf{k}_z, \mathbf{q}} (2) G_n(\mathbf{k}_z; \mathbf{q}; !)$$

$$G_{21}(\mathbf{r}; \mathbf{r}'; !) = \sum_{n, \mathbf{k}_z, \mathbf{q}} (1)_{n, \mathbf{k}_z, \mathbf{q}} (2) F_n(\mathbf{k}_z; \mathbf{q}; !) \quad (9)$$

where $! = (2m + 1) \pi$ are the electron Matsubara frequencies. Similar expressions can be written for the remaining two Nambu matrix elements. In writing (9) we have taken into account only diagonal (in Landau level index n) contributions to the Green's functions. This is a good approximation in high magnetic fields where $\hbar l_c \ll 1$ and the number of occupied Landau levels n_c is not too large, which is the case for the extreme type-II systems under consideration. In this situation we are justified in using the diagonal approximation^{1,3}, in which the BCS pairs are formed by electrons belonging to mutually degenerate Landau levels located at the Fermi surface while the contribution from Landau levels separated by $\hbar l_c$ or more is included in the renormalization of the effective coupling constant ($g \rightarrow g(H; T)$)¹³. As long as the magnetic field is larger than some critical field $H_c(T)$ the off-diagonal pairing does not change the qualitative behavior of the superconductor in a magnetic field. The critical field H_c at $T = 0$ can be estimated from the dHvA experiments to be $0.5 H_{c2}$ for A-15 and $0.2 H_{c2}$ for borocarbide superconductors⁴.

When Nambu matrix (9) is inserted in Eq. 7 and the space average in (2) is performed, the longitudinal $G_{xx}(\mathbf{i}) = G_{yy}(\mathbf{i})$ and transverse (Hall) $G_{xy}(\mathbf{i}) =$

$G_{yx}(\mathbf{i})$ current-current correlation functions become

$$i_j(\mathbf{i}) = \frac{1}{4m^2 l^2} \sum_{n, \mathbf{k}_z, \mathbf{q}} \text{Tr} [{}_3 G_n(\mathbf{k}_z; \mathbf{q}; \mathbf{i} + \mathbf{i}') {}_3 G_{n+1}(\mathbf{k}_z; \mathbf{q}; \mathbf{i}')] \quad (10)$$

where the + sign corresponds to $G_{xx}(\mathbf{i})$, the - sign corresponds to $G_{xy}(\mathbf{i})$ and $! = (2m + 1) \pi$ are electronic Matsubara frequencies. On the other hand the longitudinal (parallel to the external magnetic field) current-current correlation function $G_{zz}(\mathbf{i})$ becomes

$$G_{zz}(\mathbf{i}) = \frac{1}{4m^2} \sum_{n, \mathbf{k}_z, \mathbf{q}} k_z^2 (! + 2 !)^2 \text{Tr} [{}_3 G_n(\mathbf{k}_z; \mathbf{q}; \mathbf{i} + \mathbf{i}') {}_3 G_n(\mathbf{k}_z; \mathbf{q}; \mathbf{i}')] \quad (11)$$

In order to perform the summation over the Matsubara frequencies $!$, we introduce a spectral representation for the Nambu matrix $G_n(\mathbf{k}_z; \mathbf{q}; !)$ as

$$G_n(\mathbf{k}_z; \mathbf{q}; !) = \sum_1^Z d!_1 \frac{A_n(\mathbf{k}_z; \mathbf{q}; !_1)}{!_1} \quad (12)$$

where the spectral function matrix $A_n(\mathbf{k}_z; \mathbf{q}; !)$ is defined as

$$A_n(\mathbf{k}_z; \mathbf{q}; !) = -\frac{1}{\pi} \text{Im} G_n^{\text{ret}}(\mathbf{k}_z; \mathbf{q}; !) \quad (13)$$

When the spectral representation of the Green's functions (12) is used back in (10) and (11) respectively, we obtain

$$i_j(\mathbf{i}) = \frac{1}{4m^2 l^2} \sum_{n, \mathbf{k}_z, \mathbf{q}} d!_1^Z d!_2^Z \frac{n+1}{2} \text{Tr} [{}_3 A_n(\mathbf{k}_z; \mathbf{q}; !_1) {}_3 A_{n+1}(\mathbf{k}_z; \mathbf{q}; !_2)] \quad (14)$$

and

$$G_{zz}(\mathbf{i}) = \frac{1}{4m^2} \sum_{n, \mathbf{k}_z, \mathbf{q}} k_z^2 d!_1^Z d!_2^Z \text{Tr} [{}_3 A_n(\mathbf{k}_z; \mathbf{q}; !_1) {}_3 A_n(\mathbf{k}_z; \mathbf{q}; !_2)] \quad (15)$$

where S contains Matsubara sums i.e.

$$S = \frac{1}{i} \sum_{l=1}^{\infty} (-1)^{l+1} \frac{1}{(i + i l)^2 (i l)^2} : \quad (16)$$

The sum can be evaluated in the standard way by picking up the contributions from each of the poles of the summand¹¹. After the analytic continuation $i l \rightarrow i$ we obtain the retarded function S_{ret}

$$S_{\text{ret}} = \frac{(2l_2 + 1)^2 n_F(l_2) - (2l_1)^2 n_F(l_1)}{l_2^2 l_1 + i} \quad (17)$$

where $n_F(l)$ is the Fermi function.

In order to obtain the imaginary part of $\chi_{ij}(\omega)$ we need to find an imaginary part of S_{ret} when calculating the longitudinal conductivity $\chi_{xx}(\omega; T)$ and $\chi_{zz}(\omega; T)$. On the other hand, since S_{ret} enters the expression for $\chi_{xy}(\omega)$ in (14) we need to find the real part of S_{ret} . Using the identity

$$\frac{1}{x + i} = P \frac{1}{x} - i \delta(x) \quad (18)$$

and taking the imaginary part of (16), we find that the diagonal conductivities become

$$\begin{aligned} \frac{\chi_{xx}}{T} = \frac{\chi_{yy}}{T} = & \frac{1}{4m^2 T^2} \sum_{n, k_z, q} \sum_{l=1}^Z d! \frac{(2l + 1)^2 n_F(l) - n_F(l + 1)}{T^2} \\ & \frac{n + 1}{2} \text{Tr} [{}_3A_n(k_z; q; l + 1) {}_3A_{n+1}(k_z; q; l) + {}_3A_{n+1}(k_z; q; l + 1) {}_3A_n(k_z; q; l)] \end{aligned} \quad (19)$$

and

$$\frac{\chi_{zz}}{T} = \frac{1}{4m^2} \sum_{n, k_z, q} k_z^2 \sum_{l=1}^Z d! \frac{(2l + 1)^2 n_F(l) - n_F(l + 1)}{T^2} \text{Tr} [{}_3A_n(k_z; q; l + 1) {}_3A_n(k_z; q; l)] \quad (20)$$

Similarly, taking the real part of (16) with the help of (18) yields for the off-diagonal conductivity:

$$\begin{aligned} \frac{\chi_{xy}}{T} = \frac{\chi_{yx}}{T} = & \frac{1}{4m^2 T^2} \sum_{n, k_z, q} \sum_{l=1}^Z d! \frac{(2l + 1)^2 n_F(l) - n_F(l + 1)}{T^2} \\ & \frac{n + 1}{2} \text{Tr} [{}_3B_{n+1}(k_z; q; l + 1) {}_3A_n(k_z; q; l) - {}_3B_n(k_z; q; l + 1) {}_3A_{n+1}(k_z; q; l)] \end{aligned} \quad (21)$$

where the function $B_n(k_z; q; l + 1)$ is defined as

$$B_n(k_z; q; l + 1) = \sum_{l=1}^{Z+1} d! \frac{A_n(k_z; q; l)}{l^2 l_1 + i} : \quad (22)$$

III. GREEN'S FUNCTIONS IN THE PRESENCE OF DISORDER

Before further discussing expressions (19), (20) and (21) we should go back to the question of spectral functions or, alternatively, Green's functions for the superconductor in a magnetic field. The Green's function for the clean superconductor can be easily found following Ref. 14 with their Fourier transforms in the quasi-

momentum space expressed in the Nambu formalism as

$$G_n = \frac{1}{(i!)^2} \frac{1}{E_n(k_z; q)} \frac{i! + n(k_z)}{n(q)} \frac{n(q)}{i!} \frac{1}{n(k_z)} \quad (23)$$

where

$$E_{n,p}(k_z; q) = \hbar v_F \sqrt{\frac{q^2}{2} + \frac{1}{2} (n + p)^2} \quad (24)$$

$$n(k_z) = \frac{\hbar^2 k_z^2}{2m} + \hbar v_F (n + 1/2)$$

is the quasiparticle excitation spectrum of the superconductor in high magnetic field near points $k_z = k_{Fn} =$

$2m(\hbar v_F(n + 1/2)) = \hbar^2$ calculated within the diagonal approximation^{1,3}, where $\hbar v_F = 1$. For the quasiparticles near the Fermi surface ($k_z = k_{Fn}$) it suffices to consider only the $E_{n,p=0}$ bands. The gap, $\Delta_n(q)$, which in the MSR representation can be written as

$$\Delta_n(q) = \frac{1}{2} \frac{1}{2^{n+m}} \sum_{k_x} \exp(i \frac{b_x}{a} k_x^2) \exp(2ik_q b_y - (\frac{k}{a})^2 \frac{1}{2}) H_{n+m}[\frac{1}{2}(\frac{k}{a} + \frac{k}{a})] \quad (25)$$

tends to zero on the Fermi surface at the set of points in the MBZ with a strong linear dispersion in q . The excitations from other, $p \neq 0$ in (24), bands are gapped by at least a cyclotron energy and their contribution to the quasiparticle transport can be neglected at low temperatures ($T \ll T_c$). Once the off-diagonal pairing in (9) is included, the excitation spectrum cannot be written in the simple form (24) and a closed analytic expression for the superconducting Green's function cannot be found. Nevertheless, when these off-diagonal terms are treated perturbatively as in Ref. 3 the qualitative behavior of the quasiparticle excitations, characterized by the nodes in the MBZ, remains the same. This statement is correct in all orders of the perturbation theory and therefore is exact as long as the perturbative expansion itself is well defined i.e. as long as $H > H_c(T)$. Once the magnetic field is lowered below H_c , gaps start opening up at the Fermi surface signalling the crossover to the low-field regime of quasiparticle states localized in the cores of widely separated vortices¹⁵.

In a dirty but homogeneous superconductor with the coherence length much longer than the effective distance l_{imp} over which the impurity potential changes ($l_{imp} \gg 1$), the superconducting order parameter is not affected by the impurities and still forms a perfect vortex lattice. For such a system, the bare Green's function in (9) is dressed via scattering through the diagonal (normal) self-energy $\Sigma^N(i!)$ and off-diagonal (anomalous) self-energy $\Sigma^A_{nn}(q; i!)$.¹⁴ A dressed Green's function is obtained by replacing $i!$ with $i!$ and $n(q)$ with $\tilde{n}_n(q)$ in (9) where

$$\tilde{n}_n(q) = \frac{i!}{n(q)} + \frac{\Sigma^A_{nn}(q; i!)}{n(q)} \quad (26)$$

In order to calculate the spectral functions in (19) the analytical continuation should be performed so that $G_{ret}(k_z; q; i!) = G(k_z; q; i! - i)$ where $\Sigma^N_{ret}(i!) = \Sigma^N(i! - i)$ with the impurity scattering rate in the superconducting state defined as $(i!) = -\text{Im} \Sigma^N_{ret}(i!)$. It was shown by the authors in Ref. 14 that the anomalous self energy does not qualitatively change the form of the gap function $\Delta_n(q)$ at low energies and therefore $\Sigma^A_{nn}(q; i!)$ will be neglected in further calculations. At the same time, the real part of the normal self energy $\Sigma^N(i!)$ can be either neglected or absorbed into $n(k_z)$.

IV. THERMAL CONDUCTIVITIES IN T → 0 LIMIT

We are interested in calculating thermal conductivities in (19) and (21) in the limit of $T \rightarrow 0$ and small T such that $T \ll T_c$. In the limit of $T \rightarrow 0$ the difference of Fermi functions in (19) becomes

$$\frac{n_F(i! + i) - n_F(i!)}{i!} \approx \frac{\partial n_F}{\partial i!} \quad (27)$$

This function is sharply peaked around $i! = 0$ at very low temperatures so that we are justified in expanding the integrand in (19) and (21) around $i! = 0$ up to second order in $i!$ and setting the scattering rate to a constant $(i! = 0)$. In the high-field superconductors the largest contribution to the thermal conductivity comes from the quasiparticle excitations at the Fermi surface with momenta q such that $q = \max(T; \xi)$ while the excitations gapped by large q give exponentially small contributions. Therefore, in order to simplify the integration over the MBZ and summation over the Landau level index in (19) and (21) we linearize the excitation spectrum (24) around nodes at the Fermi surface⁵. This enables us to obtain approximate but analytic expressions for thermal transport coefficients which capture the qualitative behavior near H_{c2} . Keeping this in mind and with the help of the Sommerfeld expansion¹⁶ the longitudinal conductivity $\kappa_{xx}(H; T) = \kappa_{yy}(H; T)$ and $\kappa_{zz}(H; T)$ at low temperatures become

$$\frac{\kappa_{xx}(H; T)}{\kappa_{xx}^N(H; T)} = \left(\frac{4}{3} - 1\right) - \frac{1}{5} + \frac{7}{5} \left(\frac{3}{2} - 1\right) \frac{k_B T}{\xi} \quad (28)$$

and

$$\frac{\kappa_{zz}(H; T)}{\kappa_{xx}^N(H = 0; T)} = -\frac{1}{5} + \frac{7}{15} \frac{k_B T}{\xi} \quad (29)$$

$\kappa_{xx}^N(H; T)$ is the thermal conductivity of the normal metal in a magnetic field¹⁷

$$\kappa_{xx}^N(H; T) = \frac{2}{3} \frac{n_e}{2m} \frac{4}{(\hbar v_F)^2 + 4} T \quad (30)$$

where $n_e = \frac{1}{2\pi^2} k_{Fn}^3$ is electronic density in the system. On the other hand the transverse conductivity $\sigma_{xy}(H;T) = \sigma_{yx}(H;T)$ becomes

$$\frac{\sigma_{xy}(H;T)}{\sigma_{xy}(H;T)} = \left(\frac{4}{N} - 1\right) - \frac{2}{5} + \frac{7}{5} \left(1 - \frac{3}{N}\right) \frac{k_B T}{\hbar \omega_c} \quad (31)$$

where $\sigma_{xy}(H;T)$ is the off-diagonal thermal conductivity of the normal metal in magnetic field¹⁷

$$\sigma_{xy}(H;T) = \frac{2}{3} \frac{n_e}{m \omega_c} \frac{(\hbar \omega_c)^2}{(\hbar \omega_c)^2 + 4 T^2} T \quad (32)$$

Relations (28), (29) and (31) obtained when $\omega_c = 1$ within the "linearized spectrum approximation" tell us that there is still a considerable thermal transport in the mixed state of the superconductor. This is in stark contrast to the exponential suppression of transport characteristic of an s-wave superconductor in zero field. Furthermore, relations (28), (29) and (31) indicate that when passing from the normal to the superconducting state, both longitudinal and transverse transport coefficients $\propto T$ are reduced from their respective normal state values by the factor $(\omega_c)^2$ (the term linear in $(T)^2$ is negligible at low temperatures even for very clean superconductors). The factor $(\omega_c)^2$ measures the fraction of the Fermi surface G containing gapless quasiparticle excitations at $T = 0$. The size of G is determined by both the total number of nodes in the excitation spectrum (24) and the areas in different branches where the BCS gap is very small but not necessarily zero. This result, obtained here for the thermal coefficients, is consistent with the behavior of some other superconducting observables that measure the presence of low-energy excitations at the Fermi surface. One such experimentally confirmed behavior is the reduction of the de Haas-van Alphen (dHvA) oscillation's amplitude in both A-15 and borocarbide superconductors when the sample becomes superconducting⁴. The drop in the overall amplitude in passing from the normal to the superconducting state reflects the presence of a small portion of the Fermi surface

G containing coherent gapless excitations while the rest is gapped by large Δ .⁵

V. COMPARISON WITH EXPERIMENT

Recently, the longitudinal thermal conductivity of the borocarbide superconductor $\text{LuNi}_2\text{B}_2\text{C}$ was measured down to $T = 70$ mK by Boaknin et al.¹⁰ in a magnetic field from $H = 0$ to above $H_{c2} = 7$ Tesla. In the limit of $T \rightarrow 0$, a considerable thermal transport is observed in the mixed state of the superconductor ($H_{c1} < H < H_{c2}$), indicating the presence of delocalized low-energy excitations at the Fermi surface. The authors argue that this observation is strong evidence for a highly anisotropic gap function in $\text{LuNi}_2\text{B}_2\text{C}$, possibly with nodes. On the other hand, no sizable thermal conductivity was observed in zero field, the result expected for a superconducting gap without nodes.

The Boaknin et al. result is consistent with the observation of dHvA oscillations down to fields $H < H_{c2} = 5$ in $\text{YNi}_2\text{B}_2\text{C}$, a close cousin of $\text{LuNi}_2\text{B}_2\text{C}$ as well as in V_3Si where the oscillations persist down to fields $H < H_{c2} = 2.4$. It was shown by us that the drop in the dHvA amplitude observed in these experiments can be attributed to the quantization of quasiparticle orbits within the superconducting state which results in the formation of nodes in the gap⁵. This quantum regime behavior in fields $H < H < H_{c2}$ is due to the center-of-mass motion of the Cooper pairs, in contrast to the d-wave or anisotropic s-wave where nodes in the gap are due to the relative orbital motion. Therefore it makes sense to compare the theory developed in this paper with the experimental data in Ref. 10. A quick check tells us that the expression (28), where $(H) = (H) < 1$, does not hold through the entire range of fields used in the experiment. Therefore, we numerically compute the longitudinal thermal conductivity directly from Eq. 19, without using any additional approximations, for both the borocarbide superconductor $\text{LuNi}_2\text{B}_2\text{C}$ as well as for the A-15 superconductor V_3Si .

In the limit of $\omega_c \rightarrow 0$ and $T \rightarrow 0$ the expression (19) yields

$$\frac{\sigma_{xx}}{T} = \frac{2}{12m \hbar \omega_c} \frac{X}{(n+1)} \sum_{k_z, q} \frac{1}{E_{n,p=0}^2(k_z; q) + \frac{1}{2}} \frac{1}{E_{n+1,p=0}^2(k_z; q) + \frac{1}{2}} \quad (33)$$

where the number of Landau levels involved in superconducting pairing $n_c = E_F / \hbar \omega_c$ varies as a function of magnetic field. In the borocarbide superconductor $\text{LuNi}_2\text{B}_2\text{C}$ n_c can be estimated as $n_c \approx 33$ at H_{c2} and $n_c \approx 1147$ at field of $H = 0.2$ Tesla (these numbers

were obtained using an effective mass of $0.35m_e$ and Fermi velocity $v_F = 2.76 \cdot 10^7$ cm/s as reported in Ref. 18). On the other hand, the number of occupied Landau levels in the A-15 superconductor V_3Si is much larger: $n_c \approx 241$ at $H_{c2} = 18.5$ Tesla and $n_c \approx 4470$

at $H = 1$ Tesla (we used an effective mass of $1.7m_e$ and Fermi velocity $v_F = 2.8 \cdot 10^7$ cm/s from Ref. 19 in this estimate). The scattering rate $\tau^{-1} (= 0)$ in (33) is, in general, modified relative to the normal state scattering rate τ_0 when the system becomes superconducting. Indeed, the self-consistent calculation of in Ref. 14 gives $\tau(H) = \tau_0(H) = 2$. We assume $\tau(H) = \frac{1}{H - H_{c2}}$ which is a good approximation for the range of fields used in the experiment.

The dashed line in Fig. 1 shows the magnetic field dependence of the quasiparticle thermal conductivity $\kappa = T$ for the borocarbide superconductor $\text{LuNi}_2\text{B}_2\text{C}$ in the limit of $T \rightarrow 0$ obtained by the numerical evaluation of (33), where values for the BCS gap and normal state inverse scattering rate τ_0 are taken from Ref. 10. The full circles in Fig. 1 are the experimental data of Boaknin et al.¹⁰ for the same superconductor. The full line in Fig. 1 shows the theoretical plot obtained by numerical evaluation of (33) for the A-15 superconductor V_3Si where values for Δ and τ_0 are taken from Ref. 19. There is a significant difference in the behavior of $\kappa = T$ in these two superconducting systems characterized by much smaller thermal transport in V_3Si when compared to the transport in $\text{LuNi}_2\text{B}_2\text{C}$ in the same range of magnetic fields. This observation indicates that the number of gapless or near gapless excitations at the Fermi surface in the V_3Si is very small at $H \rightarrow H_{c2}$. In order to understand this difference, one has to notice that in magnetic fields $H < H_{c2} = 0.5H_{c2}$ the number of occupied Landau levels in V_3Si system is huge (~ 4500) and that V_3Si is away from the regime of coherent gapless excitations of high fields. On the other hand, the number of occupied Landau levels in $\text{LuNi}_2\text{B}_2\text{C}$ is much smaller (~ 1000) and it seems that there are still many gapless excitations left at low fields. It is surprising though that significant thermal transport exists down to $H \rightarrow 0.15H_{c2}$, a field much smaller than the critical field $H_{c2} = 0.2H_{c2}$ for this system, where most of the quasiparticle spectrum should be gapped. Note, however, that a possible source for such a significant transport at low fields might be the highly anisotropic s-wave gap function in $\text{LuNi}_2\text{B}_2\text{C}$, as suggested in Ref. 10. If there is such anisotropy along one or more directions on the Fermi surface, the range of validity of our theory may be extended to fields lower than the simple estimate for H_{c2} .²⁰ In this regard, we alert the reader that at the lowest fields in Fig. 1 ($H \rightarrow 0.04H_{c2}$) our theory is stretched to its very limits and its quantitative accuracy diminishes.

VI. CONCLUSIONS

In this paper we develop expressions for the longitudinal and transverse quasiparticle thermal conductivities for an extreme type-II superconductor in a magnetic field. We utilize the Landau level formalism of superconducting pairing in a magnetic field to obtain, within the Kubo mechanism of linear response to an external perturba-

FIG. 1: Magnetic field dependence of the quasiparticle longitudinal thermal conductivity computed from Equation (33) for $\text{LuNi}_2\text{B}_2\text{C}$ (dashed line) and V_3Si (full line). Full circles represent experimental data of Boaknin et al.¹⁰ The vertical dotted line indicates the normal-superconducting transition at $H_{c2} = 7$ Tesla for $\text{LuNi}_2\text{B}_2\text{C}$. The upper critical field for V_3Si at $H_{c2} = 18.5$ Tesla is not shown. For $\text{LuNi}_2\text{B}_2\text{C}$ we have used experimentally determined values for $\Delta = 4.4$ meV and $\tau_0 = 0.5$ from Ref. 10 as well as the effective mass $m = 0.35m_e$ from Ref. 18. For V_3Si , $\Delta = 2.6$ meV, $\tau_0 = 0.61$ meV and $m = 1.7m_e$ were taken from Ref. 19.

tion, thermal currents perpendicular and parallel to the external magnetic field. From there, current-current correlation functions are introduced within the Matsubara finite temperature mechanism in order to derive closed expressions for thermal conductivities $\kappa_{ij}(\omega; T)$. We examine the transport coefficients $\kappa_{ij} = T$ in the limit of $T \rightarrow 0$ and $T \neq 0$ and find that there is considerable thermal transport in the fixed state of a superconductor with an s-wave symmetry due to the creation of gapless excitations in the magnetic field. This is in contrast to the zero field thermal transport which is exponentially small for an s-wave superconductor with no nodes in the gap. Furthermore, when passing from the normal to the superconducting state the thermal coefficients $\kappa_{ij} = T$ become reduced with respect to their normal state values by a factor $(\kappa/\kappa_0)^2$ which measures the fraction of the Fermi surface that contains coherent gapless or near gapless excitations in a magnetic field. In this respect, thermal conductivities behave similarly to the dHvA oscillations in which the amplitude is also reduced at the superconducting transition. Finally, we numerically compute the longitudinal thermal conductivity for two realistic superconducting systems, the borocarbide $\text{LuNi}_2\text{B}_2\text{C}$ and the A-15 superconductor V_3Si . The thermal transport in $\text{LuNi}_2\text{B}_2\text{C}$ is much larger in magnitude than the thermal transport of V_3Si at the same field. This result indicates that the borocarbide $\text{LuNi}_2\text{B}_2\text{C}$ might still be in the regime of delocalized quasiparticle states even at fields much lower than the critical field $H_{c2} = 0.2H_{c2}$.

(estimated from the dHvA experiments^{4,20}). The agreement of our theoretical plot with the experimental data for LuN_{1/2}B₂C taken by Boaknin et al.¹⁰ over a wide range of fields used in the experiment is surprisingly good.

ACKNOWLEDGEMENT

The authors would like to thank E. Boaknin and L. Taillefer for sharing their knowledge of the subject with

us. This work is supported by a grant from the Research Corporation (SD and TPP) and by the NSF Grant DMR00-94981 (ZT).

- ²⁰ In a clean s-wave superconductor $x = H/H_{c2}$ can be estimated as a solution of the equation $x^3 = \frac{2}{E_F} \frac{4}{(h v_{c2})^3} (1 - x)^2$ and yields $H = 0.2 - 0.5 H_{c2}$ for the systems in question (see Ref. 4). This estimate depends on the value of the s-wave gap function and can be much smaller than $0.2 - 0.5 H_{c2}$ if the value of minimum gap in a strongly anisotropic s-wave case is significantly different from the accepted BCS value.
