We exam ine the superconducting an isotropy  $_{c} = (m_{c}=m_{ab})^{1-2}$  of a metallic high-T<sub>c</sub> superconductor M gB<sub>2</sub> by measuring the magnetic torque of a single crystal. The anisotropy  $_{c}$  does not depend sensitively on the applied magnetic eld at 10 K.We obtain the anisotropy parameter  $_{c} = 4:31$  0:14. The torque curve shows the sharp hysteresis peak when the eld is applied parallel to the boron layers. This comes from the intrinsic pinning and is experimental evidence for the occurrence of superconductivity in the boron layers. \pacs{74.25.Ha, 74.60.-w}

#### I. IN TRODUCTION

Since the discovery of superconductivity in M gB<sub>2</sub><sup>1</sup> considerable progress has been m ade in determ ining the physical properties of this material. The new materials are metallic and hence promising in considering the applications in the various elds. The extrem e high-T<sub>c</sub> (39 K) gives a doubt whether or not the superconductivity can be explained within a conventional BCS fram ework. Tunneling studies show that the material is reasonably isotropic and has a well developed s-wave energy gap.<sup>2,3</sup> The anisotropy parameter  $_{c} = (m_{c}=m_{ab})^{1=2}$  of M gB<sub>2</sub> in the literature ranges from 1.2 to 9 in polycrystalline sam ples.<sup>4</sup> Therefore, it is highly desirable to investigate the fundam ental properties of M gB<sub>2</sub> by using a single crystal. Recently, X u et al.<sup>5</sup> succeeded in synthesizing the single crystals by the vapor transport method and reported the superconducting properties of M gB<sub>2</sub>.

The rst principle calculation by K ortus et al.<sup>6</sup>, by Choi et al.<sup>7</sup>, and by Y ildirim et al.<sup>8</sup> suggested that the boron layers govern the superconductivity. The boron isotope e ect on  $T_c$  supports this idea.<sup>9</sup> However, the experimental con mation of the superconductivity in the boron layers is not thoroughly convincing so far.

Torque is a sensitive tool for probing the various kinds of an isotropy, and has been successfully applied to investigate the highly an isotropic high- $T_c$  cuprates. The electronic an isotropy of high- $T_c$  cuprates was investigated by Farrell et al.<sup>10</sup> and Ishida et al.<sup>11</sup> The high- $T_c$  cuprates are characterized by the extrem electronic an isotropy  $_c = m_c = m_{ab} =$ 200 as well as the layered structure of superconductivity. The superconductivity is governed by the CuO<sub>2</sub> layers or by the CuO<sub>2</sub> bilayers. An alternative stacking of the CuO<sub>2</sub> layer and the blocking layer is a key concept both in crystal structure and in the occurrence of the superconductivity. This is also the origin of the intrinsic pinning for vortices in high- $T_c$  superconductors. The M gB<sub>2</sub> structure consists of an alternative stacking of the boron layer and the magnesium layer, too. It is of special interest to investigate the sim ilarity and dissimilarity between this new m aterial M gB<sub>2</sub> and the cuprate superconductors.

It is crucial to discrim inate the intrinsic pinning from various other pinning sources. The magnetic torque has an advantage to see the vortex pinning as a function of angle with respect to a crystalline axis. Since the intrinsic pinning works e ectively when the eld is almost in parallel to the  $CuO_2$  planes, it manifests as a hysteresis peak in torque.<sup>12,13</sup> Therefore, a torque is a sensitive probe for sensing an intrinsic (directional) pinning.

In this paper, we report the electronic anisotropy of  $M gB_2$  by m eans of the magnetic torque. We also describe evidence for the intrinsic pinning in  $M gB_2$  when the eld is applied parallel to the boron layers. This ensures that the superconductivity occurs in the boron layers.

#### II. EXPERIMENTAL

### A. Sam ple

The details of the single crystal preparation of  $M gB_2$  is reported by Xu et al.<sup>5</sup> They reported that the onset tem perature of superconductivity is 38.6 K. Because of the severe volatility of M g and the high melting point of B,

M gB<sub>2</sub> single crystals were grown in a closed system. The starting material of M g is 99.99% and B is 99.9% in purity. A molar ratio of 1:1.9 of the starting materials was sealed inside a molybdenum crucible of internal diameter 10 mm, length 60 mm by the electron beam welding. The molybdenum crucible was used in a high frequency induction furnace. The crucible was rst heated to 1400 C at a rate of 200 C/h and kept for 2 h, then slow ly cooled to 1000 C at a rate of 5 C/h, and nally to room temperature by switching o the power. A plate-like single crystal of M gB<sub>2</sub> (  $0.11 \text{ mm}^2$  14 m) is used for the torque measurements. The c-axis is perpendicular to the plate. The sample weight is too tiny to measure by our electronic balance of resolution 0.01 m g.

#### B. Torque

A split-type superconducting magnet changes a magnetic eld continuously from 60 kG to + 60 kG, and has a variable temperature insert from 4 K to 300 K. A torque detection system is attached on the top of the insert. A phosphor bronze string hangs a balance arm, a feedback coil, and a quartz sample rod in a helium -gas atmosphere from the main ange. The feedback coil (300 turns of 0.075-mm Cu wire) is located in a special hollow cylindrical NdFeB permanent magnet (M agnetic Solutions) of a transverse eld of 5000 G to 8000 G. A sample torque can be cancelled by a controlled torque given by a torque detection mechanism at the top of the insert. W e use an optical position sensor to maintain the sample direction. The sample can be rotated by a stepper motor (a resolution of 0.0036). The torque dynamic range is from  $10^3$  dynam to  $+10^3$  dynam with a sensitivity of 10<sup>3</sup> dynam.

## III. RESULTS AND DISCUSSIONS

W emeasured the torque of a single crystalline M gB<sub>2</sub> as a function of  $_{c}$ . The angular step was chosen as 0.5 degrees. The inversible torque was extracted by  $_{irr}() = (_{dec}() _{inc}())=2$  and the reversible torque was obtained as  $_{rev}() = (_{inc}() + _{dec}())=2$  where  $_{inc}()$  and  $_{dec}()$  are the torques as a function of increasing and decreasing angle, respectively.

In Figs. 1 and 2, we show the reversible torque  $_{rev}$  of M gB<sub>2</sub> at 10 K (10 kG, 20 kG, 30 kG) and the reversible torque  $_{rev}$  of M gB<sub>2</sub> at 10 K (40 kG, 50 kG, 60 kG), respectively. The shape of the torque curves in Figs. 1 and 2 is sim ilar to the torque curve of Y Ba<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub>.<sup>11</sup> This indicates that the M gB<sub>2</sub> superconductor is an isotropic with respect to the c axis. In the three-dimensional an isotropic London m odel in the mixed state, the angular dependence of the torque is given by K ogan<sup>14</sup> as

$$_{\rm rev}(_{\rm c}) = \frac{_{0}{\rm H}{\rm V}}{_{16}{\rm ^{2}}} \frac{_{\rm c}^{2}}{_{\rm c}^{1=3}} \frac{\sin 2_{\rm c}}{_{\rm (c)}{\rm c}} \ln f \frac{_{\rm c}{\rm H}_{\rm c2}^{2}}{_{\rm H}{\rm (c)}{\rm g}} g$$
(1)

where  $(_{c}) = (\sin^{2}_{c} + \frac{2}{c}\cos^{2}_{c})^{1=2}$ , c is the angle between the applied eld and the caxis,  $_{c} = \frac{p}{m_{c}=m_{ab}}$ ,  $H_{c2}^{?}$  is the upper critical eld perpendicular to the ab plane (1), V is the sample volume. This equation is relatively simple, and has frequently been employed in the literature to analyze the electronic anisotropy of various high-T<sub>c</sub> cuprates.<sup>10,11,15</sup> The computer tting of <sub>rev</sub> to the K ogan m odel gives the anisotropy parameter <sub>c</sub> = 2.8 4.8 where  $H_{c2}$  is xed to 60 kG.<sup>5</sup>

As shown in Fig. 3, the torque curve measured in 10 kG at 10 K has a hysteresis against the angle scans. The torque as a function of increasing as well as decreasing angle has a sharp peak at  $_{\rm c}$  ' 90. This is well known as an intrinsic pinning peak for the high-T<sub>c</sub> cuprates.<sup>11,12</sup> The dashed line is the reversible component (see the tted line in the top gure of Fig. 1). The peak appeared near 90 represents the manifestation of intrinsic pinning in this novel superconductor. This is experimental con mation of the superconductivity in the boron layers.<sup>6,7,8</sup> The remarkable hysteresis of the torque curve give rise to the uncertainty in the reversible torque obtained by rev () = (inc() + dec())=2. Actually, c in 10 kG is appreciably less than those in other elds at 10 K. A tiny intrinsic pinning peak can be seen in the torque curve at 20 kG. Note that the torque curves are alm ost reversible for 30 kG, 40 kG, 50 kG, and 60 kG.

The  $_{\rm c}$  is alm ost independent of eld between 20 kG and 60 kG at 10 K.W e om itted  $_{\rm c}$  in 10 kG to obtained the averaged <  $_{\rm c} > = 4.31$  0.14. This is som ew hat larger than those reported in the literature.<sup>4</sup>

A ngst et al.<sup>16</sup> also reported the torque m easurem ent of M gB<sub>2</sub>. Their m easurem ent regim e is com plim entary to us. They mainly use the torque as a sensitive m eans of determ ining H<sub>c2</sub> as a function of angle <sub>c</sub>. However, the determ ination of H<sub>c2</sub> is dependent on the criterion of the torque onset, and their criterion contains a target parameter <sub>c</sub>. The upper critical eld H<sub>c2</sub> (<sub>c</sub>) thus obtained is analyzed by the elective m assmodel. They obtained = 6 at 15 K and = 2.8 at 35 K. They also used the K ogan m odel to analyze the torque data and found the eld dependence

of  $_{\rm c}$ . They interpreted it in terms of the double gap structure of M gB<sub>2</sub>. We note that this is not the case in our torque measurements because  $_{\rm c}$  is almost independent of eld at 10 K.

W e attempted to measure the temperature dependence of the torque curve in 60 kG, but the signal noise ratio is not satisfactory enough to analyze the torque data. This is due to the sm allness of the M gB<sub>2</sub> crystal. It is inconclusive on the temperature dependence of  $_{\rm c}$ . Measurements using a larger crystal are desirable for the detailed studies of the M gB<sub>2</sub> system.

Finally, we estimate a weight of our MgB<sub>2</sub> sample from the torque amplitude. In the K ogan model, we obtain a prefactor of  $_{0}$ H V =16  $^{2}$  by the least squares thing where the penetration depth should read as =  $(_{c} _{ab}^{2})^{1=3}$ . In Fig.4, we plot  $_{0}$ H V =16  $^{2}$  as a function of H. The data points are approximately the by a straight line. From the slope, one determ ine the sample volume V. By assuming  $_{ab} = 85 \text{ nm}$ , the density = 2:63 g/cm<sup>3</sup>, and  $_{c} = 4:31$  we estimate the mass m of our sample is 5 g. We note that the mass calculated from the measured size of crystal and the density of M gB<sub>2</sub> is approximately 3.3 g.

#### IV. CONCLUSIONS

The torque curves at 10 K are almost reversible in elds larger than 20 kG. The electronic anisotropy of M gB<sub>2</sub> is determined by the torque as  $_c = 4.31$  0.14. The new superconductor exhibits an intrinsic pinning at 10 K in 10 kG when the eld is applied parallel to the boron layers. There is a modulation of the order parameter in M gB<sub>2</sub> along the c axis. This indicates that the boron layers, as suggested from the st principle calculations,<sup>7</sup> govern the superconductivity. The M gB<sub>2</sub> superconductor is rather sim ilar to the high-T<sub>c</sub> cuprates while the anisotropy of M gB<sub>2</sub> is moderate compared to the cuprates.
