## Self-consistent theory of pair distribution functions and e ective interactions in quantum C oulom b liquids

B.Davoudi<sup>1;2</sup>, M.Polini<sup>1</sup>, R.Asgari<sup>1;2</sup>, and M.P.Tosi<sup>1</sup>

 $^1\rm N\,E\,ST$  –IN FM and C lasse di Scienze, Scuola Norm ale Superiore, I-56126 P isa, Italy $^2$  Institute for Studies in Theoretical Physics and M athem atics, Tehran 19395–5531, Iran

W e use a density-functional theoretical approach to set up a computationally simple self-consistent scheme to calculate the pair distribution functions and the electric interactions in quantum C oulom b liquids. W e demonstrate the accuracy of the approach for dierent statistics and space dimensionalities by reporting results for a two-dimensional electron gas and for a three-dimensional boson plasm a over physically relevant ranges of coupling strength, in comparison with M onte C arb data.

PACS num bers: 05.30.-d, 71.10.Ca, 71.45.G m

Exchange and correlations in systems of interacting electrons have been a focus of interest in many-body physics for many decades. An important manifestation of these e ects is the equilibrium distribution of electron pairs, which provides a picture of the short-range order in the system . Know ledge of this distribution for a hom ogeneous electron uid as a function of its density determ ines its ground-state energy and is essential in the construction of energy functionals for the study of atom s, m olecules and solids in applications of density functional theory (DFT) transcending a local-density approxim ation [1]. Recent developments in DFT have drawn attention to the utilization of inhom ogeneous electron-pair densities for such studies [2]. There also is an interest for uids of charged bosons in quantum statistical mechanics, e.g. in regard to condensates of point-like Cooper pairs as models for super uid states [3].

W e present in this Letter a novel theory of the pair distribution function g(r) in hom ogeneous uids of charged, point-like ferm ions or bosons. We start from some basic results of DFT [4] and tackle the evaluation of g(r) through the solution of two-particle scattering problem s which are governed by e ective scattering potentials em bodying the many-body e ects. This view point, which was rst taken by 0 verhauser [5] and further developed in subsequent studies [6, 7], is here in plem ented through a self-consistent inclusion of exchange and correlations leading back, when a non-self-consistent linear-response approximation is made, to the spin-dependent e ective interactions derived in the early work of Kukkonen and Overhauser [8]. Calculations on uids of electrons in dimensionality D = 2 and of charged bosons in D = 3 are shown to yield results in excellent agreem ent with available Quantum Monte Carlo data over a physically signi cant range of coupling strength. A spreviously noted, the method can be extended to pair distributions in inhom ogeneous Coulom b uids [7].

W e consider a quantum uid ofpoint-like particles having charge e and mass m at zero tem perature, neutralized by a uniform charged background. The uid consists of di erent com ponents at average density n (two spin com ponents for spin-1=2 ferm ions, for instance). As already stated, our aim is to use DFT for building a selfconsistent theory that gives the pair distribution functions as output. From the Hohenberg-Kohn theorem [4], the ground-state energy of the uid in the presence of a set of external potentials V  $^{\text{ext}}$  (r) can be written as

$$\begin{array}{c} E_{gs}[fn \ (r)g] = T_{s}[fn \ (r)g] + E_{H}[fn \ (r)g] \\ X \\ + d^{D} r V^{ext}(r) n \ (r) + E_{Q}[fn \ (r)g] \end{array}$$
(1)

where fn (r)g is the set of densities of all components, n (r) n (r) n , and  $T_s$  is the ideal kinetic energy functional. The H artree term  $E_{\mu}$  is given by

$$E_{H} = \frac{1}{2} X^{2} x^{D} r^{D} r^{0} v (jr r^{0} j) n (r) n (r^{0})$$
,
(2)

where  $v(jr r^0) = e^2 = jr r^0 j$ . The last term in Eq. (1) is the exchange-correlation energy functional, containing the quantum m any-body (QMB) e ects. In Eqs. (1) and (2) the presence of a neutralizing background has been taken into account.

The quantity n [g (r) 1], where g (r) is the component-resolved pair distribution function, can be viewed as the distortion that a particle of the uid (of

-type at position r = 0) produces in the density proles [9]. Here, g (r) is de ned through the average number of -type particles inside a spherical shell of radius r and thickness dr centered on a -type particle located at the origin, which is given by n g (r)  $_{\rm D}$  r<sup>D</sup> <sup>1</sup>dr with  $_2 = 2$  and  $_3 = 4$ . The appropriate groundstate energy functional is obtained from Eq. (1) with the form al replacements V <sup>ext</sup> (r) ! v(r) and n (r) ! n [g (r) 1]. Finally, the QMB energy functional can be written via an adiabatic connection form ula,

$$E_{Q}^{()}[fn (r)g] = \frac{1}{2} \frac{X}{r} \frac{1}{e^{2}} \frac{Z}{e^{2}} \frac{Z}{d} \frac{Z}{d^{D}r} \frac{Z}{d^{D}r^{0}v(jr r^{0})}$$

$$n (r)n (r^{0}) g (r;r^{0}) 1 ; (3)$$

where n(r) = n g(r) and  $g(r; r^0)$  measures the probability of nding two particles with indices and

at r and  $r^0$  when a -type particle is at the origin, the interaction potential being v (jr  $r^0$ ) =  $e^2 = jr$   $r^0$ j. O f course, g (r; $r^0$ ) depends functionally on fn (r)g.

The Kohn-Sham mapping [4] ensures that n (r) can be built from Kohn-Sham scattering orbitals  $_{\rm k}$  (r) which satisfy the following set of Schrödinger equations:

$$\frac{2}{2}r_{r}^{2} + V_{ks} (r) = \mathbf{w}_{kk} (r) :$$
 (4)

Here, r is the relative distance of two particles, = m =2 is the reduced m ass, and " $_{\rm k}$  =  $\sim^2 k^2$ =2 with  $\sim k$  the relative m om entum . The scattering potential  $V_{\rm K\,s}$  (r) in Eq. (4) can be obtained from the rst functional derivative of E $_{\rm gs}$  T $_{\rm s}$  with respect to n (r),

$$V_{KS}(\mathbf{r}) = \mathbf{v}(\mathbf{r}) + \frac{X}{n} \frac{Z}{d^{D}} r^{0} \mathbf{v}(\mathbf{j}\mathbf{r} - r^{0} \mathbf{j}) \mathbf{n} (\mathbf{r}^{0}) + \frac{E_{0}^{(1)}}{n(\mathbf{r})};$$
(5)

F inally, the pair distribution functions can be obtained from the K ohn-Sham scattering states as

$$g (\mathbf{r}) = \begin{bmatrix} x \\ k & j_k & (\mathbf{r}) \end{bmatrix}^2$$
(6)

where the sum runs over all occupied states labelled by k. The occupation factors  $_{k}$  depend on the statistics of the uid (see the discussion below). Notice that Eq. (6) guarantees positive de niteness of g (r).

In the above form al developm ent, the functional dependence of the QMB energy on density is not known and we have to resort at this point to some approximations. Their goodness can only be gauged a posteriori. Firstly, the function g  $(r;r^0)$  in Eq. (3) involves three-body correlations and would lead us into a hierarchy of higherorder correlation functions. The simplest way of truncating this hierarchy is to replace g  $(r;r^0)$  by g  $(jr r^0)$ , in analogy with what has been done in treating the equation of motion for the W igner distribution function in the presence of external potentials [10]. Secondly, we expand the QMB energy in a functional Taylor series in powers of n (r) up to second order term s. W ith the de nition

$$f (jr r^{0}) = \frac{{}^{2}E_{o} [fn (r)g]}{n (r) n (r^{0})} f_{n (r)g=0}$$
(7)

we nd in Fourier transform

$$V_{KS}(q) = v(q) + v(q) [I G (q)] n (q) : (8)$$

Here, G (q) f (q)=v (q) are the so-called local eld factors, de ned in term of the Fourier transform f (q) of the QMB kernels in Eq. (7), and v (q) is the Fourier transform of the C oulom b potential (i.e.  $v(q) = 4 e^2 = q^2$ in D = 3,  $v(q) = 2 e^2 = q$  in D = 2). It may be worth exploring in the future alternative approximations to a truncated expansion of the QMB energy. The approximations that have led us to Eq. (8) can be justiled in a weak-coupling regime and indeed Eq. (8) yields back the electron-electron interactions of K ukkonen and O verhauser [8] when n (q) is related to the scattering potential  $V_{\text{KS}}$  (q) by linear response theory. We propose instead to carry out a self-consistent calculation of the pair distribution functions and of the elective interactions through the solution of the set of equations (4), (6) and (8). For this purpose the quantities n (q) in Eq. (8) should be written in the form

where S (q) are the partial structure factors, related to the pair functions by

$$S(q) = + p \frac{d^{D}}{n n} d^{D} r [g(r) 1] exp(iq r):$$
(10)

The uselfulness of such a self-consistent approach will be explored in the numerical calculations reported further below. Here we remark that setting G (q) = 0 in Eq. (8) gives back the self-consistent H artree approximation (HA), that we have found to yield quite satisfactory results for g(r) in the 3D electron gas for values of the coupling strength up to at least  $r_s = 10$  [7].

Let us examine the application of the above selfconsistent scheme (SCS) to a 2D param agnetic electron gas (EG), where correlations are stronger than in 3D. The Greek indices become spin indices taking the values = 1. For the details of the sum mation procedure in Eq. (6), the reader is referred to Refs. [6] and [7]. The necessary input are the local-eld factors G  $_{\circ}$  (q), for which we use Q uantum M onte C arb (QMC) data [11] as described by interpolation form ulae in Ref. [12]. These refer to the charge-charge and spin-spin eld factors,  $G_{+}(q) = [G_{**}(q) + G_{**}(q)]=2$ and G (q) =  $[G_{**}(q) - G_{**}(q)] = 2$ , which in the longwavelength lim it satisfy the compressibility and susceptibility sum rules,  $G_{+}(q) ! ( \begin{bmatrix} 1 & 1 \\ 0 \end{bmatrix} = \begin{bmatrix} n^{2} v(q) \end{bmatrix}$  and  $G_{+}(q) ! \begin{bmatrix} 2 \\ B \end{bmatrix} ( \begin{bmatrix} 1 \\ p \end{bmatrix} = \begin{bmatrix} 1 \\ s \end{bmatrix}) = v(q)$ . Here, 0 and p are the compressibility and the Pauli susceptibility of the ideal Fermigas, and s are the corresponding quantities for the EG, and  $_{\rm B}$  is the Bohrmagneton. We recall that these expressions, though strictly valid only in the therm odynam ic lim it, give in practice a good account of G (q) over a range of q extending alm ost up to  $2k_{\rm F}$  [11, 12].

Figure 1 reports our SCS results for the spin-averaged pair distribution function  $g(r) = [g_{""}(r) + g_{"\#}(r)]=2$  in the 2D EG at  $r_s = 5$  and 10, where  $r_s = (na_B^2)^{1=2}$  is the usual coupling-strength parameter with  $a_B$  the Bohr radius. The results of a QMC study by S.M oroni (private communication) and of our previous HA approach are also shown in Figure 1. It is seen that inclusion of exchange and correlation in the present SCS reproduces the form ation of a rst-neighbor shell with increasing coupling strength, which is m issed in the HA [7], and yields satisfactory quantitative agreement with the QMC data.

Figure 2 reports the SC S results for the spin-symmetric component of the electron-electron interaction,  $V_{KS}(\mathbf{r}) = [V_{KS}^{""}(\mathbf{r}) + V_{KS}^{"\#}(\mathbf{r})]=2$ , for the 2D EG at  $\mathbf{r}_{s} = 5$ , as well as its Fourier transform  $\mathfrak{F}_{KS}(\mathbf{q})$  (shown in the inset). We nd very signi cant changes from the HA and indeed the original treatment of exchange and correlations in a linear-response approximation by Kukkonen and O verhauser [3] are not very far from our SC S results.

We should remark at this point that the present SCS is not as accurate in reproducing the spin-resolved pair distribution functions of the 2D EG and hence the spin-spin e ective interaction. Numerical evidence that an empirical inclusion of higher-order terms in the scattering potentials can yield full agreement with the QMC data, as well as extensions to larger values of  $r_s$ , will be reported in future work.

Here we discuss instead how our approach can be extended into a fully self-consistent scheme (FSCS), in which the local eld factors are self-consistently determ ined over the relevant q-range during the calculation rather than taken as input from QMC.We need for this purpose a closure relation between G (q) and S (q), and the crucial point is that it should self-consistently satisfy the therm odynam ic (com pressibility and susceptibility) sum rules. Such a closure can be obtained by using Eq. (3) in Eq. (7), with the aforem entioned approximation g (r;r<sup>0</sup>) ' g (jr r<sup>0</sup>j). The details of this calculation will be reported elsewhere. The nal result is

$$G (q) = D G (q) :$$
 (11)

Here, the di erential operator D is de ned by

D 
$$1 + n \frac{0}{0} + n \frac{0}{0} + \frac{1}{2}n n \frac{0^2}{0};$$
 (12)

while G (q) is given by

G (q) 
$$\frac{1}{P\frac{1}{n n}} \frac{1}{e^2} \int_{0}^{Z} d^{2} \frac{d^{2} q^{0}}{(2 )^{p}} \frac{v(q^{0})}{v(q)}$$
  
S  $(\dot{j}q + q^{0})$ ; (13)

with S (q) being the partial structure factor at coupling constant . A lthough these expressions are strictly correct only in the long-wavelength lim it, they yield a good account of QMC data on the local eld factors over the relevant range of q [11, 12], as already noted.

It can be seen from Eqs. (11)-(13) that, in order to satisfy the susceptibility sum rule in the param agnetic EG, one needs to move into a partially spin-polarized state and indeed evaluate the full range of spin polarization up to the ferrom agnetic state. For a simple illustration of our method we have therefore considered a 3D uid of spinless charged bosons (CBF), where the proposed FSCS simpli es drastically. At zero tem perature all bosons in the reference Kohn-Sham ideal gas are in the k = 0 state, so that  $g(r) / j_{k=0}(r)f$ . The scattering orbital  $_{k=0}(r)$  is a spherically sym metric function and the Kohn-Sham Schrodinger equation becomes equivalent to the Euler-Lagrange equation for g(r) as obtained from the variational principle using the von W<sub>R</sub>eizsacker functional for  $T_s$  [13],  $T_s[g(r)] = (\sim^2 n=8)$  d<sup>D</sup> r jr g(r) f = g(r). Furthermore, the local eld factor G (q) from Eqs. (11)-(13) satisfies the compressibility sum rule, i.e.  $\lim_{q \to 0} G(q) = [n^2 v(q)]^1$  with being the compressibility of the interacting Bose liquid.

We have solved the FSCS based on Eqs. (4), (6), (8) and (11)-(13) for a 3D CBF at coupling strength (4  $na_B^3 = 3$ ) <sup>1=3</sup> up to 20. The main results are rs shown in Figures 3 and 4. In Figure 3 we compare the FSCSg(r) with QMC data by M oroniet al. [14] and with SCS results where the QMC data for the local eld factor [14] have been used as input. Our results for g (r) are in excellent agreem ent with QMC and with each other, the in plication being that our self-consistent determ ination of G (q) from the compressibility sum rule also accounts with su cient accuracy for this function over the relevant range of q (see also the inset in Figure 4, where the FSCS G (q) is compared with the QMC data). In the inset in Figure 3 we include, with the FSCS results and the QMC data for g(r) at  $r_s = 20$ , also the results obtained in the HA and those of Apaja et al. [3] based on a hypernetted chain (HNC) approximation. Again, the HA is not able to reproduce quantitatively the formation of a rst-neighbor peak with increasing coupling. Finally, in the main body of Figure 4 we illustrate the self-consistency that we have obtained in the values of the compressibility from the ground-state energy and from G (q), as well as their excellent agreem ent with Q M C data by M oroniet al. [14].

In sum mary, we have proposed a self-consistent approach by which the pair correlations (and related quantities such as the internal energy) of a quantum C oulom b uid can be determined, ultimately using the partial mean densities of its components as the only input. We have examined its usefulness in dierent statistics (fermions and bosons) and space dimensionalities (D = 2 and 3) in comparison with available QMC data, extending up to relatively large values of the C oulom b coupling strength. We have also highlighted the role of exchange and correlations in determining the emergence of liquid-like structure with increasing coupling strength through the formation of a rst-neighbor shell and further oscillations in the pair distribution function.

This work was partially supported by M IUR through the PR IN 2001 program. We are grateful to Prof. G. V ignale for stimulating discussions and to Dr. S.M oroni for giving us access to his QMC results for the 2D EG prior to publication.

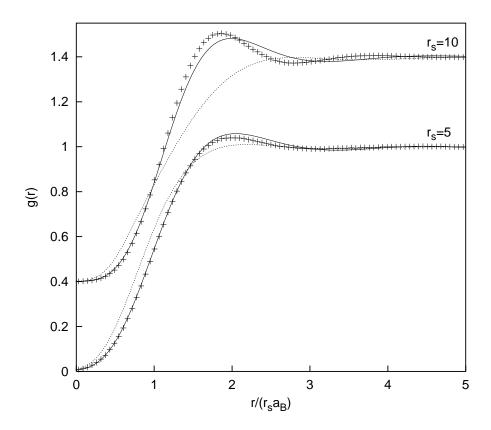

FIG.1: The pair distribution function g(r) in a 2D EG at  $r_s = 5$  and 10, as a function of  $r=(r_s a_B)$ . The results of the SCS (full line) and of the HA (dotted line) are compared with QMC data (crosses). The curves at  $r_s = 10$  have been shifted upwards by 0.4.

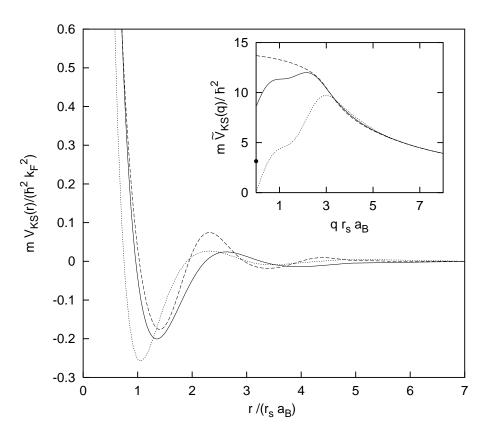

FIG.2: The spin-sym metric electron-electron interaction  $V_{KS}(r)$  in a 2D EG at  $r_s = 5$ , as a function of  $r=(r_sa_B)$ . The result of the SCS (full line) is compared with the HA (dotted line) and with the Kukkonen-O verhauser result (dashed line). The inset shows the Fourier transform of  $V_{KS}(r)$  as a function of  $qr_sa_B$ . The black dot gives the long-wavelength limit of the Thom as Ferm i theory for the electron-test charge interaction.

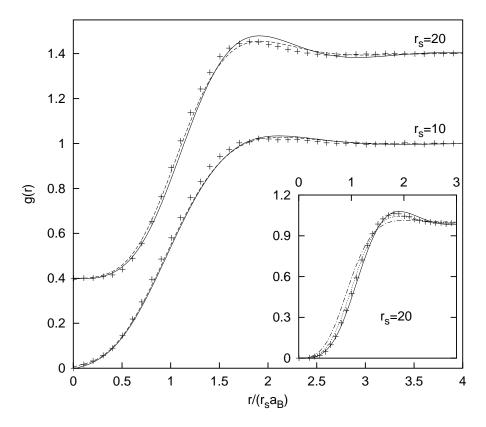

FIG.3: The pair distribution function g(r) in a 3D CBF at  $r_s = 10$  and 20, as a function of  $r=(r_s a_B)$ . The results of the FSCS (full line) and of the SCS (dashed line) are compared with QMC data (crosses). The curves at  $r_s = 20$  have been shifted upwards by 0.4. In the inset, the HA result (dash-dotted line) is compared with the FSCS (full line), the QMC data (crosses), and the HNC of Apaja et al. (dotted line).

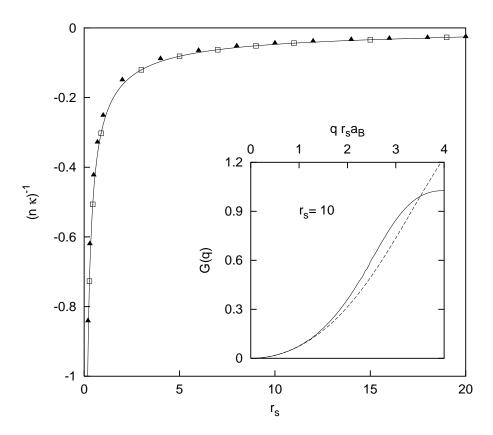

FIG.4: (n ) <sup>1</sup> in Ryd as a function of  $r_s$  for a 3D CBF.The results of the FSCS from the ground-state energy (full line) and from the self-consistent G (q) (empty boxes) are compared with QMC data (triangles). The inset shows G (q) as a function of  $qr_sa_B$  at  $r_s = 10$ : the FSCS (full line) is compared with QMC data (dashed line).
