Recently, Kotzler et al. [1] measured the frequencydependent conductance for YBa2Cu307 and interpreted their results as evidences that the decay of the super uid density is caused by a 3D vortex loop proliferation m echanism and a dimensional crossover when the correlation length _c along the c axis becom es com parable to the sample thickness d. In this Comment, we show that the com plex conductance data presented in Ref. 1 have characteristic key features not com patible with their analysis, which are instead described by the existing phenom enology of 2D vortex uctuation in Ref. 2 associated with a partial decoupling of CuO₂-planes. It is also argued that the suggested dim ensional crossoverm akes the uctuations stronger, and accordingly shifts the transition towards lower tem perature. This appears to be opposite to the conclusion in Ref. 1.

In Fig.1, G⁰ in the complex conductance $G = G^{0} + iG^{00}$ from Fig.2 in Ref.1 is replotted as $!G^{0}L_{k}$, with the kinetic inductance L_{k} (T) extracted in Ref.1. In Ref.1, it is assumed that $!L_{k}$ (T)G(!;T) = S($!=!_{0}$) with a scaling function S = S⁰ + iS⁰⁰ satisfying

$$S^{0} = 1 = [1 + (! = !_{0})]$$
 (1)

and S⁰ is obtained from the K ramer-K ronig relation [2]. K otzler et al. nd that their data can be characterized by 0:7, which corresponds to the heights of the dissipation peaks equal to 0.23 (solid line in Fig. 1). However the data exceed this value by m ore than 40%,

increasing frequency, whereas Eq.(1) predicts constant peak heights: These observations in ply that the scaling function (1) cannot properly describe the experimental data. The 2D vortex explanation, on the other hand, predicts that the peak heights should system atically increase with ! and should always be between 1 = 0.32and 0.5 (dashed and dotted lines in the Fig. 1) [2, 3]. The lower value 1 = corresponds to the M innhagen response form [given by = 1 in Eq. (1)] associated with bound vortex-antivortex pairs dom inating close to the K osterlitz-Thouless (KT) transition. The higher value 1=2 corresponds to the D rude response [given by = 2 in Eq. (1)], dom inated by abundant free vortices well above the KT transition. B oth free vortices and bound pairs

are present above the KT transition with the proportion

of free vortices increasing with T. This explains why the

and the peak height shows a system atic increase with

peak heights increase with T [2, 3]. Kotzleret al. link their proposed mechanism to an apparent sam ple independent on set of deviation at about 35 (nH) 1 for the inductive data taken at 1kH z from the inferred 3D L_k^{-1} . The relevant scale where vortex type uctuations become important may be estimated from the KT transition criteria $L_k^{1} = 8.2 \quad 10^{2} T$ (K nH) ¹ giving L_k^{1} 7 (nH) ¹ for the samples in Ref. 1. This places the KT-transition (which in principle always can be associated with a large enough sample of nite thickness) very close to the inferred 3D transition. A lthough 35 (nH) 1 is larger, it is still of the sam e order of m agnitude. This suggests that the deviation at 1kH z occurring below the inferred critical $T_{\rm c}$ (as well as below the inferred KT-transition) may indeed be caused by vortex loops. However, in such a scenario the deviation from the inferred zero frequency L_k^{1} towards higher values is due to the nite frequency [2]. This deviation would then vanish in the lim it of sm all frequency (sm all in the sense that the dissipation peaks in Fig. 1 cease to move to the left) in plying a frequency dependent onset of deviations. Any change of the 3D L_k^{-1} caused by a dimensional crossover ($_{\rm c}$ > d) will always increase uctuations and cause deviation in the lim it of zero frequency to the left instead of to the right of the inferred 3D L_k^{-1} .

In our scenario the deviation occurs when $!=!_0$ becomes large which always happens for a T below T_c because $!_0 ! 0$ at T_c . The reason is that the larger $!=!_0$ the more of the larger vortex bops become ine ective in renormalizing L_k^{-1} , causing an increase from the !=0-

value [2]. The universality found in Ref.1 in plies that $!_0 / L_k^{-1}$ which is similar to what happens in the 2D XY m odel [4]. The point to note is that in order for the data to deviate to the right of the ! = 0-data the uctuations involved in the ! = 0-data should be the ones that are made ine ective by the nite frequency. Since the ! = 0-data obeys the 3D critical scaling the relevant uctuations would have to be the usual vortex loops. C onsequently the data is well explained w ithout invoking a vortex blow out involving an additional $_c=d-1$ condition.
