We analyze fulleride superconductivity at experimental doping levels, treating the electronelectron and electron-phonon interactions on an equal footing, and establish the existence of novel physics which helps explain the unusually high superconducting transition temperatures in these system s. The Jahn-Teller phonons create a local (intram olecular) pairing that is suprisingly resistant to the C oulom b repulsion, despite the weakness of retardation in these low -bandwidth system s. The requirement for coherence throughout the solid to establish superconductivity then yields a very strong doping dependence to T $_{\rm c}$, one consistent with experiment and much stronger than expected from standard E liashberg theory.

The discovery of superconductivity in alkali-doped C₆₀, persisting up to unexpectedly high temperatures $(T_c = 33 \text{ K} [1] \text{ or } T_c = 40 \text{ K} [2])$, raises interesting questions about superconductivity in low-bandwidth molecular solids. Superconductivity arises from an e ective attractive interaction between the electrons. In conventional superconductors a net attractive interaction survives, in spite of the strong Coulomb repulsion, thanks to retardation e ects [3]. However, retardation is small for the fullerides [4,5], since the molecular vibration frequencies are com parable to the bare electron bandwidth. We show that the combination of molecular solid character and coupling to Jahn-Teller phonons produces a local pairing, important for superconductivity, which is not strongly suppressed by the C oulom b repulsion. In addition, the transition tem perature depends anom alously strongly on the doping level. The superconducting mechanism in fullerides therefore di ers in important ways from that of conventional superconductors.

Conventional superconductors are studied in the Migdal-Eliashberg theory, assuming a band width W much larger than a typical phonon frequency ! ph. For the fullerides, ! ph W, so the E liashberg theory is of questionable accuracy. This failure of E liashberg theory is typically thought to lower T_c [6] (although the opposite has also been argued [7]). M etallic fullerides have very large, nonsaturating resistivities in the norm al state [8,9] suggesting \bad m etal" behavior [10] which is also expected to reduce T_c [10]. However, we nd that T_c in the fullerides is not generally lower than expected from E liashberg theory due to an unusual cancellation of countervailing e ects. The violation of E liashberg theory asserts itself explicitly in a very strong doping dependence ofT_c.

In A₃C₆₀ (A = K, Rb), the three-fold degenerate t_{lu} level is partly occupied and couples strongly to eight H_g intram olecular Jahn-Teller phonons. We capture the essential physics using a model with one t_{lu} level and one H_g mode per molecule, with a dimensionless electron-phonon coupling strength . We also include the hopping between the molecules and the Coulomb repulsion U between two electrons on the same molecule [11]. The

m odel explicitly includes Jahn-Teller coupling and places no implicit restrictions on the ratio $!_{ph}=W$ or the value of .We refer to this model as the T h problem.To revealthe novele ects of Jahn-Teller character, we com pare thism odel to a nondegenerate (a) or two-fold degenerate (e) level interacting with a non-Jahn-Teller A_{α} or two-fold degenerate (E_q) phonon, i.e., T a,E e and a problem s, respectively. Typical param eters are А 0:5 1, !_{ph}=W 0:1 0:25 and U=W 1:5 2:5 [12].

W e circum vent the limitations of E liashberg theory by using the dynam icalm ean- eld theory (DMFT) [13] with a non-perturbative Q uantum M onte-C arb (QMC) technique [14]. The electron self-energy is assumed to be q-independent, allowing a mapping of the lattice problem onto an electric in purity problem . We study superconductivity by applying a perturbation creating electron pairs and calculating the corresponding response function, i.e. the q = 0 pairing susceptibility . A divergence of below a temperature $T_{\rm c}$ signals the onset of superconductivity [15]. We write

$$= (1 _0)^{\perp} _0; (1)$$

where $_0$ is obtained from products of two fully dressed electron G reen functions describing the propagation of two electrons (holes), which do not interact with each other. Eqn. (1) then de nes the electrice interaction W e de ne a local (intram olecular) pairing susceptibility

$$\begin{split} & \overset{\text{loc}}{X} \begin{pmatrix} 1; 2; 3; 4 \end{pmatrix} = \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 1 \end{pmatrix} c_{m}^{y} \begin{pmatrix} 2 \end{pmatrix} c_{m}^{0} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} c_{m}^{0} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} c_{m}^{y} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} c_{m}^{y} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} c_{m}^{y} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}} \begin{pmatrix} 0 \end{pmatrix} (2) \\ & \overset{\text{point}}{R_{m}^{y}}$$

where h:::i denotes a therm all average and m labels the $t_{1\mathrm{u}}$ levels on one molecule. Then

$$loc = (1 \ 0 \ loc \ loc) \ 1 \ 0 \ c) \ (3)$$

^{loc} and ^{loc} can be calculated within DMFT; this denes the local interaction ^{loc}. ^{loc} should be a rather good approxim ation, since the interaction is dom inated by intram olecular phonons and an intram olecular Coulomb repulsion. Since $_0$ can be calculated within DMFT, follows from Eqn. (1).

Putting $_1 = _2$, $_3 = _4$ and taking the Fourier transform with respect to $_1$ $_3$ in the T ! 0 lim it, we obtain

$${}^{\text{loc}}(\underline{i!}_{n}) = {}^{\text{loc}}(\underline{"}) = (\underline{"} \quad \underline{i!}_{n}); \qquad (4)$$

where

$${}^{loc}(") = {}^{X} {}^{m}; N {}^{2}j {}^{c}_{m} {}^{"}C_{m} {}^{\#}j0; N {}^{2}j$$

$${}^{n} {}^{m} {}^{m} {}^{("}E_{0}(N) + E_{n}(N {}^{2})) + ::: (5)$$

Here $j_n; N$ i is the nth excited state of the system with N electrons and the energy $E_n(N)$. The term shown describes the rem ovalof an electron pair; ":::" indicates the addition of an electron pair.

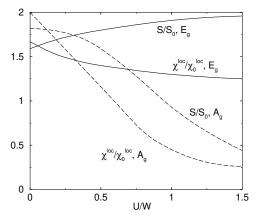

FIG.1. The ratios $S=S_0$ and $= _0$ drop as a function of U=W for = 0.7. For the non-Jahn Teller model A a, these ratios drop rapidly as U increases. In contrast, the pairing susceptibility for E = e is very resistant to increasing U. The results were obtained from exact diagonalization for an impurity model with ve host sites.

The new physics can be best understood by exam ining a sum rule for the spectral function loc ("). In the simplest Jahn-Teller case, E e,

Ζ

$$\int_{0}^{1} \int_{0}^{1} dr S = 4;$$
 (6)

for a half-lled band and in the limit of very large U and very small . In this limit the Jahn-Teller phonons produce local singlets on the molecules,

$$\frac{1}{p-2} \sum_{m}^{X} c_{m}^{y} c_{m \#}^{y} jvaci;$$
(7)

with pairing via the molecular quantum number m. Although the Jahn-Teller e ect competes with intermolecular hopping, a large U reduces hopping, so that singlets form even for small . In contrast, for $\frac{loc}{0}$ (") the corresponding sum nule gives only $S_0 = 1$. Since $\frac{loc}{0}$ tends to be larger than $\frac{loc}{0}$, the e ective interaction $\frac{loc}{0}$ (Eq. (3)) tends to be attractive. The existence of local singlets (Eq. (7)) means that the probability for removing or adding two electrons with the same m quantum number is very high. In contrast, for $_0$ the electrons' m - quantum numbers are independent and $\frac{loc}{0}$ tends to be sm aller.

As U increases, spectral weight is shifted upwards in energy, which tends to decrease bc. However, this is partly com pensated by an increase of the integrated spectralweight S, since the Jahn-Tellere ect wins when hopping is reduced (see in Fig. 1 [16]). Increasing U therefore does not rapidly elim inate a negative bc, as one might have expected. In contrast, for the A a model the Coulomb repulsion U and the electron-phonon coupling directly compete, so S (and therefore ^{loc}) drops quickly as U is increased. These results illustrate one important aspect of m olecular solids with Jahn-Teller phonons: counter-intuitively, Coulomb interactions can in certain respects actually help electron-phonon coupling. Capone et al. [17] have reached sim ilar conclusions for A_4C_{60} using a di erent approach.

A nother important aspect is screening. The C oulom b interaction is well-screened by the transfer of electrons between the m olecules [18,4,19]. A lthough this helps superconductivity, it also norm ally implies an equally effective screening of the electron-phonon interaction itself. However, since the H_g phonons do not shift the center of gravity of the electronic levels, they cannot be e ciently screened by charge transfer on and o the m olecule [18,19].

Both these e ects are missing for A_g phonons. A_g phonons furtherm ore tend to cause instabilities when coupled to a degenerate level. W ithin a sem iclassical approximation, a molecular solid with U = 0 becomes unstable when & 1 = (2N), where N is the orbital degeneracy. A QMC calculation for a T a model supports this result, whereas in the T h case the system stays metallic for . 1 (and U = 0). To be able to use a reasonably large , we therefore study the A a system below.

A lthough it is now clear that Jahn-Teller phonons can cause local pairing, as described by $^{\rm loc}=\frac{\rm loc}{\rm 0}$ and $^{\rm loc}$, superconductivity requires the form ation of a coherent state through the solid. W ith a nite coherent m etallic weight at the chem ical potential and an attractive interaction , the divergent unperturbed uniform pair propagator $_{\rm 0}$ m ediates a pairing instability towards form ing the coherent superconducting state.

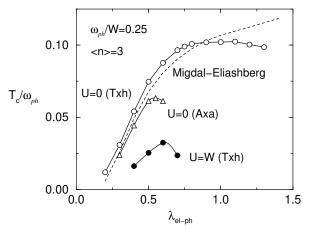

FIG. 2. T_c as a function of according to M igdal-E liashberg (dashed line) and DMFT theories for the T h () and A a (4) couplings at half-lling. The parameters are $!_{ph}$ = 0.25 and U = 0. The T h results for U = W () are also shown.

To obtain explicit results for the superconducting transition, we use DMFT calculations solving the elective in purity problem using QMC [20,21]. We instidicuss the case U = 0. Fig. 2 shows T_c as a function of according to the DMFT and Eliashberg [22] theories. The Eliashberg theory is expected to overestim ate T_c ofdoped C₆₀ both because of the violation [6] of M igdal's theorem and because the mean-eld Eliashberg equations are insu cient for a bad metal [10]. Surprisingly, in the T h model for U = 0, the Eliashberg T_c remains accurate even up to relatively large values of . In contrast, for the A a problem the Eliashberg theory fails at sm aller [23]. The DMFT calculation shows a maximum T_c at

1 due to a rapid drop of $_0$ with increasing beyond this range (Eq. (1)). For small , $_0$ goes as 1=(1 +), which renormalizes to =(1 +) in the M dM illan equation [26]. For a larger , how ever, $_0$ drops m uch faster in the DM FT than in the E liashberg theory; the form ation of a coherent state is less e cient, since spectral weight rapidly transfers away from the chem ical potential as the system approaches a m etal-insulator transition.

We next discuss nite U, connecting to Fig. 1. The solid points of Fig. 2 show the overall reduction in T_c for nite U. Fig. 3 shows T_c as a function of U for the T h and A a models. For A a, T_c drops quickly when U increases, as expected. However for T h, T_c is more resistant to increasing U [27]. This is consistent with the local pairing of Fig. 1 and illustrates the importance of treating explicitly the dynam ic interplay between Jahn-Teller phonons and electrons in molecular systems with W !_{ph}.

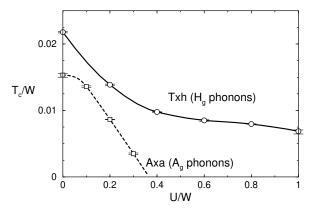

FIG.3. T_c as a function of U for the T h and A a models for half-lling. The parameters are = 0.6 and $!_{ph}=W = 0.25$. The gure illustrates the important dierence between H_g and A_g phonons.

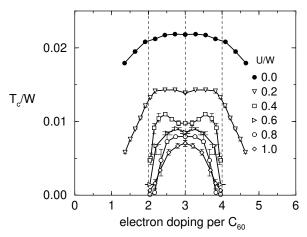

FIG.4. T_c as a function of doping n for di erent values of U for T h coupling. The parameters are $!_{ph}=W = 0.25$ and = 0.6. The gure illustrates the strong doping dependence for U=W 0.4.

Experimentally, T_c drops quickly in fullerides when the doping n is reduced below three electrons per C₆₀ molecule [24]. This cannot be explained within Eliashberg theory: reducing n from 3 induces a slight increase of the density of states at the Ferm i energy [25], which and T_c. This has been taken as evshould increase idence for an electron-electron mechanism of superconductivity [30]. Fig. 4 shows the doping dependence of $T_{\rm c}$ in DMFT.For sm all U , $T_{\rm c}$ drops slow ly until n 2 or 4 and then starts dropping much faster: ^{loc} drops rapidly here, probably because local pairing is ine cient once the average num ber of electrons per m olecule drops below two. For U = W > 0.4, T_c drops more quickly as n = 2 is approached. The system can gain a particular large Jahn-Teller energy at n = 2 [31,32]; this moves the system towards a metal-insulator transition and shifts spectralweight in the one-electron G reen's function away

from the chemical potential [11]. The shift in spectral weight rapidly reduces $_0$ and therefore $T_{\rm c}$. Thus the strong doping dependence can be explained within an electron-phonon mechanism, and there is no need to assume an electronic mechanism.

For conventional superconductors, retardation is im – portant in reducing the e ects of the strong C oulom b repulsion [3]. For the fullerides, the retardation e ects are small, since W !_{ph} [4,5]. Local pairing and screening are therefore crucial in reducing the e ects of the C oulom b repulsion for the fullerides. An increasing C oulom b interaction does not m uch dam age superconductivity, since the concomitant reduction in hopping favors the Jahn-T eller pairing. This leads to new physics in these strongly correlated low -bandw idth m olecular solids. The importance of local pairing is consistent with the short coherence length, which is only about three tim es the C $_{60}$ -C $_{60}$ separation [28,29].
