F in ite tem perature strong-coupling expansions for the K ondo lattice m odel

J. O itm aa and W eihong Zheng^y
School of Physics, The University of New South W ales, Sydney, NSW 2052, Australia.

(D ated: April 14, 2024)

Strong-coupling expansions, to order $(t=J)^8$, are derived for the K ondo lattice model of strongly correlated electrons, in 1-, 2- and 3-dimensions at arbitrary temperature. Results are presented for the special cheat, and spin and charge susceptibilities.

I. IN TRODUCTION

This paper, the second of a sequence, studies the therm odynamic properties of the K ondo lattice model, described by the H am iltonian

$$H = t X X X X X$$

$$H = t (c_i^y c_j + h x:) + J S_i s n_i$$

$$i i i$$
(1)

The rst term describes a single band of conduction electrons, the \K ondo coupling" term represents an exchange interaction between conduction electrons and a set of localized $S = \frac{1}{2}$ spins, and the nal term allows for variable conduction electron density via a chemical potential.

The K ondo lattice model combines two competing physical elects. In the strong coupling (large jJ) limit, the conduction electrons will form local singlets (J > 0) or triplets (J < 0) with the localized spin at each site. In either case there will be a gap to spin excitations and spin correlations will be short ranged. On the other hand, at weak coupling, the conduction electrons can induce the usual RKKY interaction between localized spins, leading to magnetic order.

Despite the apparent simplicity of the model, no exact results are known, either at T=0 or at nite temperatures, in any spatial dimension. In the preceding paper we studied the ground state properties of the model at T=0, using linked-cluster series expansions. We refer to that paper for a discussion of other work, which has been, almost exclusively, restricted also to T=0. In the present paper we focus on nite temperature thermodynamic properties. We know of only a few previous studies of this kind. Roder et al. considered the ferromagnetic model in the limit J:1, on the simple cubic lattice, via a high temperature expansion. Here we treat the general J case and focus on the antiferromagnetic model. Shibata et al. have studied the 1D antiferromagnetic model via a nite-temperature DMRG approach. Haule et al. have treated the 2D case, primarily via a numerical nite temperature Lanczos method. We compare our results with this work wherever possible. Haule et al. have also considered the atom ic limit (t=0), and the order t^2 correction terms. Our work was largely motivated by this paper.

Our approach, which will be described in the following Section, treats the single site terms exactly and treats the hopping term perturbatively. It is, thus, an expansion about the \atom ic limit. We sum marize here, for completeness and for later reference, the exact results in this limit.

For variable conduction electron density there are 8 states per site: 2 states with no conduction electrons and localized spin up or down, 2 states with two conduction electrons of opposite spin, and 4 states (a singlet and 3 triplets) with one conduction electron coupled to the localized spin. For a lattice of N sites the grand partition function is

$$Z_0$$
 Trfe H $g = z_0^N$ (2)

with

$$z_0 = 2 + (e^{3K} + 3e^{K}) + 2^2$$
 (3)

and K J=4, = e , = $1=k_B T$.

The internal energy per site is given by

$$u(;T) = \frac{\theta}{\theta} \ln z_0$$

$$= \frac{\frac{3}{4}J(e^{3K} - e^{K})}{2 + (e^{3K} + 3e^{K}) + 2^{2}}$$
(4)

The fugacity can, as usual, be elim inated in favour of the electron density n by using the relation

$$n(;T) = \frac{\theta}{\theta} \ln z_0$$

$$= \frac{q + 2^2}{1 + q + 2^2}$$
(5)

where we have introduced q $\frac{1}{2}$ (e^{3K} + 3e ^K). Solving this gives

$$= \frac{q(1 + n) + p \overline{q^2(1 + n)^2 + 4n(2 + n)}}{2(2 + n)}$$
 (6)

The speci cheat is then obtained from (4) and (6) via the usual relation $C_v = \frac{du}{dT}$.

A lso of interest are the compressibility or \charge susceptibility"

$$_{C}=\frac{\varrho n}{\varrho }$$
(7)

which can be expressed as

$${}^{1} \quad {}_{c} = \frac{q(1 \quad n) + 2(2 \quad n)^{2}}{1 + q + 2} \tag{8}$$

and the magnetic susceptibility, which is given by

$$4^{-1} \quad s = \frac{1 + 4e^{K} + \frac{2}{1 + q + \frac{2}{1 + q}}}{1 + q + \frac{2}{1 + q}} \tag{9}$$

Simpler analytic results can be obtained in various limits: at high or low temperature, and at or near half-lling. Som e of these are given in Ref. 4, although they contain minor errors in a few cases.

Of course in the atom ic lim it all of these quantities are smooth functions of temperature and electron density.

II. THERMODYNAM IC PERTURBATION THEORY

Our goal is to obtain an expression for the therm odynamic potential, and hence other quantities, in powers of t=J. We work in the grand canonical ensemble and write the Hamiltonian as

$$H = H_0 + V \tag{10}$$

with

$$H_0 = J S_i S_i N_i$$
 (11)

$$H_{0} = J \quad S_{i} \quad S \quad n_{i}$$

$$V = t \quad (c_{i}^{Y} \quad c_{j} + h c;)$$

$$(11)$$

The grand partition function can then be expanded in the usualway as

$$Z_{g} = Trfe^{-(H_{0}+V)}g$$

$$= n \times \dot{x} \times Z \times Z_{r} \times O$$

$$= Z_{0} + (1)^{r} d_{1} \times d_{r} \times V (_{1}) \times V (_{r})i \qquad (13)$$

with

$$\nabla () = e^{H_0} \nabla e^{H_0}$$
 (14)

and

$$hAi = \frac{1}{Z_0} Trfe^{-H_0} Ag$$
 (15)

where Z_0 is the atom ic lim it partition function (2). The free energy (grand potential) is then given by

$$F = N \ln z_0 + X^{\frac{1}{N}}$$
 (16)

w here

and the subscript N signi es that only the part proportional to N is to be included.

This approach is, of course, well known and has been used in the past for both pure spin models and for the Hubbard model Any contribution to T_r in (17) comes from a particular cluster of sites and bonds, a \graph". It is possible to restrict the class of graphs to connected ones only, as done in Ref. 5. In our work we included also disconnected graphs, of more than one component, as they are rather easy to deal with directly. Since each bond contributes a V operator and hence a factor t, it is obvious that to carry the expansion to order t^r all topologically distinct graphs with up to r bonds need to be considered. There are a total of 115 graphs through 8th order, which is as far as we have been able to compute.

The contribution of a particular graph G to the free energy can be expressed in the form

$$T_r(G) = C_G(t=J)^r z_0^p \qquad a_{s;l,m} K^l e^{m K} s$$
 (18)

where C_G is the embedding factor, or \weak lattice constant" of graph G in the particular lattice considered, P is the number of points or vertices in the graph, the $a_{s;l,m}$ are numerical constants, and the sum contains, for each graph, a nite set of terms labeled by integers s;l;m. Evaluation of these expressions is a lengthy procedure, involving a trace over a space of S^P states and evaluation, for each term in the trace, of an r-fold multiple integral. It is possible to nd many time saving renements, but, even so, the evaluation of the worst case, the octagon, took some 260 hours of CPU time on a 1GHzCompaq alpha processor.

Having computed the T (G) factors for all graphs it is then a simple matter to combine these and to obtain, for any lattice, the free energy per site in the form

$$f = \ln z_0 + \sum_{r=2}^{X^k} z_0^r F_r (K;) (t=J)^r$$
 (19)

where the $F_{\rm r}$ are complete expressions in K and , of the form

$$F_r(K;) = X$$

$$a_{s;lm} K^{l}e^{m K s}$$
(20)

These expressions are too lengthy to display here, but can be supplied on request. To give some idea of the size, the 8th order factor F_8 contains 1042 separate term s.

From (19) and (20) one can compute expressions for the internal energy and specic heat. The internal energy can be expressed in the form

$$u = \frac{0}{0} (f)$$

$$= u_0 + \sum_{r=2}^{N} z_0^{(r+1)} E_r (K;) (t=J)^r$$
(21)

where u_0 is the atom ic lim it result (4) and the E $_{\rm r}$ (K ;) are complete expressions. The speci c heat is $C_{\rm v}=$ du=dT . For most purposes it is more useful to express the series in terms of electron density n, which can be obtained from (19) via

$$n = \frac{\theta}{\theta} (f)$$

$$= n_0 + \sum_{r=2}^{X^{\dagger}} z_0^{(r+1)} Y_r (K;) (t=J)^r$$
(22)

where n_0 is the atom ic lim it result (5) and the Y_r (K;) are, again, complete expressions in K, . For xed n and K we then use a numerical reversion procedure to obtain expansions for the fugacity, in power of t=J, which can then be eliminated from the thermodynamic functions. For half-lling (n = 1) this reversion can be carried out analytically.

In addition we have included a magnetic eld term

$$H^{0} = H \quad h \quad (n_{i;"} \quad n_{i;\#} + 2S_{i}^{2})$$
 (23)

to allow calculation of the zero-eld magnetic susceptibility s, which is expressed in the form

$${}^{1} \quad {}_{s} = {}^{1} \quad {}_{0} + {}^{1} \quad {}_{r=2} z_{0} \quad {}^{(r+1)} X_{r} (K;) (t=J)^{r}$$
(24)

where, again, the rst term is the atom ic limit result (9) and the X_r are complete expressions. The fugacity can again be eliminated in favour of the electron density, as described above.

Several checks on the correctness of our results have been made. Since temperature enters explicitly, we can take the zero temperature (K ! 1) $\lim_{x \to \infty} f(x) = f(x)$ to recover the ground state energy series f(x). Another test is the f(x) in which f(x) in (19) has a leading term of order f(x) giving an expression in powers of (t). This can be compared with the results for free electrons. Complete agreement is obtained. We are condent that our results are correct, but cannot exclude the possibility of errors not picked up by these checks.

The analysis of the results follows standard lines. For any xed K; we obtain expressions for them odynam ic quantities as a series in the single variable (t=J). For small t=J the series converges rapidly and even a naive sum gives good accuracy. Pade approximants and integrated dierential approximants allow extrapolation to larger (t=J). For xed n we obtain series for in terms of t=J, which are then substituted into corresponding expressions (20), (24) to obtain a single-variable series in (t=J), which is then evaluated as before. To calculate the specic heat it is necessary to include derivatives of with respect to temperature. For the bene to fithe reader we give in Table I coe cients for some representative cases. Other series can be supplied on request.

While the general expressions are too lengthy to write down, at high temperatures, one can expand the various quantities in powers of or K. The expressions up to order K^4 are provided in the Appendix. These are valid for all loosed-packed/bipartite lattices.

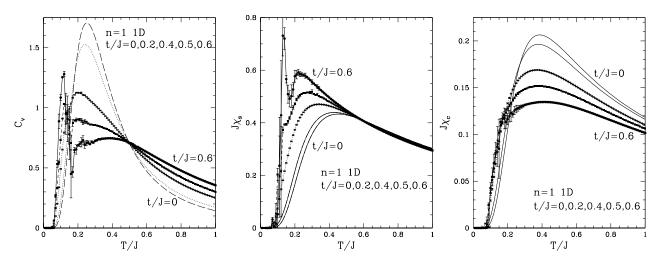

FIG.1: The specic heat C_v (a), magnetic susceptibility $_s$ (b) and charge susceptibility $_c$ (c) versus T=J for the linear chain at n=1 for t=J=0;0:2;0:4;0:5;0:6.

In the following sections we present results for the linear chain, the square lattice (sq) and the simple cubic (sc) lattice. A discussion of other lattices will be presented elsewhere.

III. THE 1D KONDO LATTICE MODEL

We consider the antiferrom agnetic model on a linear chain, with arbitrary electron concentration n. Using the procedure described above we have computed the specic heat and spin and charge susceptibilities. Figure 1(a), (b) (c) shows these quantities, as functions of temperature, for n = 1 (half-lling) for t=J=0;0.2;0.4;0.5;0.6. For $t=J^{<}0.4$ the series are well converged and the curves are obtained simply from the partial sums. For the larger values integrated differential approximants have been used, with the error bars indicating the variation between different approximants. Good agreement is obtained with the DMRG results for all three quantities. However our (relatively short) series are unable to probe the larger t=J region as well as DMRG can.

Some comments on Fig. 1 are in order. Fig. 1(a) shows the specic heat, which shows an interesting crossover from a single peak for small to a two-peak structure at larger t. In the larger t region the high temperature peak

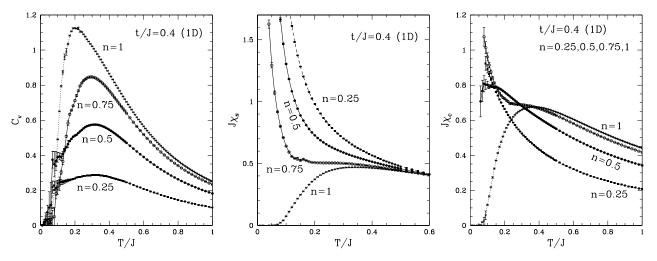

FIG. 2: The same as Fig.1, but for t=J=0.4 and n=1;0.75;0.5;0.25.

0.8

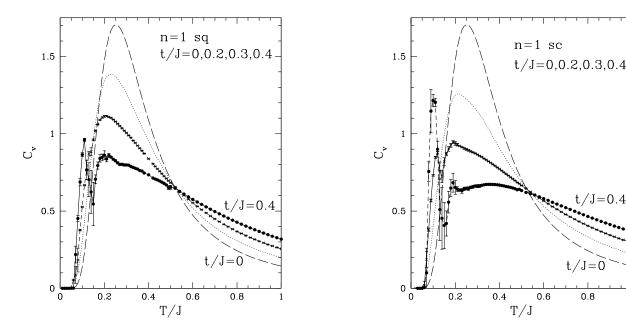

FIG. 3: The speci c heat C v versus T=J for square lattice (a) and simple cubic lattice (b) at n = 1 for t=J = 0;02;03;04.

becom es broadened and less prom inent and is, presum ably, due to conduction electrons whereas the low-tem perature peak arises from the uctuating local spins. The spin susceptibility (Fig. 1 (b)) also has a peak at a characteristic tem perature. The peak is enhanced and moves to lower Ton increasing the hopping parameter t. Increasing t=Jwill weaken the singlet correlations and a lower characteristic temperature is su cient for thermal uctuations to become dom inant. There is some indication of a double peak for t=J = 0:6, but this may be an artifact of the numerical analysis. The charge susceptibility also has peak at a characteristic temperature, and a rapid drop to zero at low tem peratures. The peak is depressed with increasing tbut the position stays relatively constant.

To display the e ect of varying conduction electron density we have chosen an intermediate value t=J=0.4 and show, in Fig. 2(a), (b), (c) curves of C_v , $_s$ and $_c$ versus tem perature for n=1,0.75,0.5 and 0.25. The high-

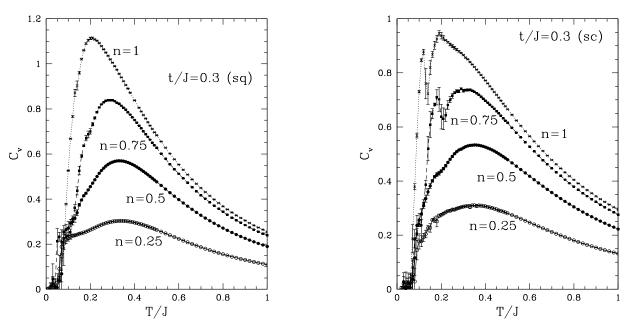

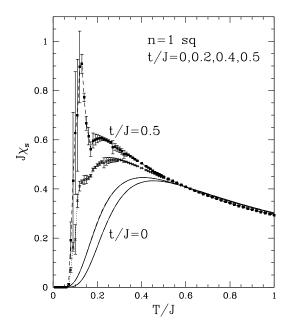

FIG .4: The speci c heat C $_{\text{V}}$ versus T=J for square lattice (a) and simple cubic lattice (b) at t=J = 0.3 for n = 1;0.75;0.5;0.25.

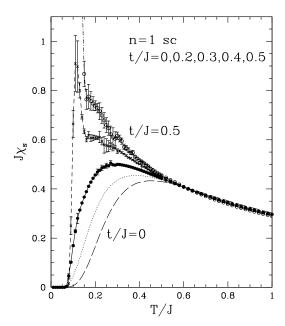

FIG. 5: The magnetic susceptibility $_{\text{S}}$ versus T=J for square lattice (a) and simple cubic lattice (b) at n=1 for t=J=0;02;03;04.

tem perature peak in C_v (Fig. 2(a)) drops roughly proportionally to n, in agreement with the assignment of this peak to conduction electrons. The series do not allow the low-T speci cheat to be determined with sulcient precision to see the electrons of doping. The sunetsugulet al. present a ground state phase diagram of the 1D K and a lattice (Fig. 6 of Ref. 8), where a transition line separates a small n ferrom agnetic phase from a large n paramagnetic phase. For the parameter ratio t=J = 0.4 the critical doping is n_c of 0.65. While there cannot be true order at in nite temperature, the marked change in the low The special cheat between the two curves with n = 0.75 and 0.5 may will be a reflection of this electron. The electron of doping on n_c is dramatic. For n = 1, at low temperatures, the system is in a gapped singlet phase and n_c goes to zero exponentially. Away from half-lling there will be free spins and n_c diverges according to the usual Curie law. The charge susceptibility n_c also shows a sharp crossover between the undoped and doped cases.

The 1D results are consistent with the, presum ably, more accurate DMRG calculations. We are not aware of any published DMRG results for special heat at inite doping, or for the susceptibility for n < 0.8. Our results conim that the series approach can be successfully applied to this model. We now turn to the 2D and 3D cases, where far less is known and where other methods have particular disculties.

IV. THE 2D AND 3D SYSTEMS

We have computed and analysed series for the specic heat, spin susceptibility and charge susceptibility for both the square and simple cubic lattices. Some representative series are given in Table I.We choose to present results for the two lattice together so as to highlight similarities and dierences between them.

Figure 3 shows the speci c heat at half-lling for various t=J ratios. The qualitative behaviour is similar to the 1D case, although smaller values of t=J su ce to produce comparable deviations from the atomic limit. A two-peak structure is manifest at t=J = 0.4. Figure 4 shows the dependence of the speci cheat on doping (for xed t=J = 0.3). The decrease with decreasing nagain consmission important the high T speci cheat is due to conduction electrons. Figures 5 and 6 show the magnetic susceptibility, at half-lling for various t=J and at t=J = 0.3 for various electron densities. Figure 6 shows a stricking crossover from n = 1, where s is structureless and vanishes as T ! 0 to lower densities

n=0.5 and 0.25 where $_{\rm S}$ appears to diverge. Evidently n=0.75 is near the critical concentration, as $_{\rm S}$ appears to start to diverge but then drops to zero. There is also some apparent structure for the 3D case at T=J ' 0.15, which m ay be an artifact of the analysis.

A mean-eld treatment suggests the existence of a nite-tem perature phase transition to a ferrom agnetic phase for small n, at least for the 3D case. To explore this we plot the inverse susceptibility versus T in Figure 7. For both lattices $_{\rm s}^{1}$ appears to vanish linearly as T! 0 at n = 0.5. For the simple cubic lattice there is some indication that the curves for $_{\rm s}^{1}$ at n = 0.25 and n = 0.1 vanish at a small nite T, con m ing a nite temperature ferrom agnetic phase. However the analysis at low temperature is imprecise and does not allow for an accurate determination of $T_{\rm c}$. The data for the square lattice appear to show no nite temperature ferrom agnetic transition.

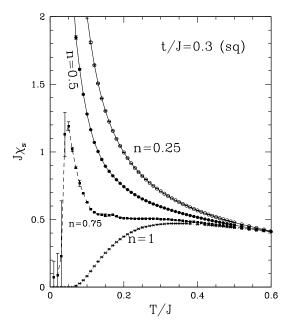

Finally in Figures 8 and 9 we show the charge susceptibility versus temperature. The behaviour is qualitatively similar to the 1D case.

V. CONCLUSIONS

We have used them odynam ic perturbation theory to investigate the antiferrom agnetic K ondo lattice model at nite temperatures. Our calculations focus, in particular, on the specic heat and spin and charge susceptibilities, and their variation both with the ratio t=J and with electron concentration. We have presented results for the linear chain, square lattice, and simple cubic lattice.

O verall, for the param eter region where our series can be analysed with reasonable precision, the behaviour of the 3 lattices is qualitatively similar. This is to be expected at moderate and high temperatures. We do, however, see an indication of a nite temperature ferrom agnetic transition in 3-dimensions for small n, consistent with expectations. This is not seen in 1- and 2-dimensions.

For the linear chain our results are in excellent agreement with the previous nite-temperature DMRG calculations³, and serve to con rm the accuracy of both methods. There are few existing results in higher dimension and our work

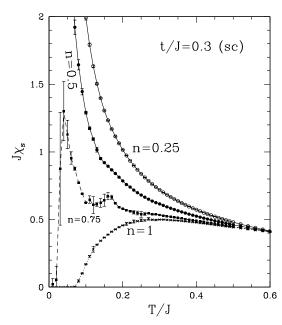

FIG. 6: The magnetic susceptibility $_{\text{S}}$ versus T=J for square lattice (a) and simple cubic lattice (b) at t=J=0.3 for n=1;0.75;0.5;0.25.

should provide a valuable benchm ark for other approaches. While we have not attempted a detailed comparison on or to experiment, this would be possible. We plan to report results for closed-packed lattices (triangular and face-centered cubic) and for the ferrom agnetic K ondo lattice model elsewhere.

Appendix

The following high tem perature expansions up to order K 4 have been obtained from the general results. The series are expressed in terms of K = J=4. The parameters are = t=J, z = coordination number, p_4 is weak embedding constant of square cluster, which has value 0, 1, 3, and 12 for 1D, square lattice, simple cubic lattice, and BCC lattice, respectively, and $z_2 = 2(4p_4 + z + z^2)=3$.

Fugacity:

$$= \frac{n}{2 n} \frac{n (1 n)^{1}}{2 n} (\frac{3}{2} + 8z^{2}) K^{2} + K^{3}$$

$$= \frac{1}{8} (11 27n + 9n^{2}) K^{4} 4z (4 3n)^{2} K^{4}$$

$$= 32z (1 6n + 3n^{2})^{4} K^{4} 32z_{2} (1 + n n^{2})^{4} K^{4} + 0 (K^{5})$$
(25)

Internal energy:

$$u=J = \frac{1}{32} n (2 \quad n) (12 + 64z^{2}) K + 12K^{2} (4 \quad 18n + 9n^{2}) K^{3} \quad 64z^{2} K^{3}$$

$$256z (2 \quad 6n + 3n^{2}) {}^{4}K^{3} \quad 256z_{2}n (2 \quad n) {}^{4}K^{3} \quad 5 (4 \quad 6n + 3n^{2}) K^{4} \quad 80z^{2} K^{4} + 0 (K^{5}) \quad (26)$$

Speci c heat:

$$C_{v}=k_{B} = n (2 n) K^{2} (\frac{3}{2} + 8z^{2}) + 3K \frac{3}{8} (4 18n + 9n^{2}) K^{2} 24z^{2} K^{2}$$

$$96z (2 6n + 3n^{2}) {}^{4}K^{2} 96z_{2}n (2 n) {}^{4}K^{2} + 0 (K^{5})$$
(27)

M agnetic susceptibility:

$${}^{1}_{s} = \frac{1}{4} + \frac{1}{8}n (2 + n) {}^{1}_{1} 2K + \frac{1}{4} (8 + 6n + 3n^{2})K^{2} + 4zn (2 + n) {}^{2}K^{2} + \frac{1}{3} (2 + 6n + 3n^{2})K^{3} + 8zn (2 + n) {}^{2}K^{3}$$

$$+\frac{1}{24}(80 \quad 180n + 198n^{2} \quad 108n^{3} + 27n^{4})K^{4} + \frac{2}{3}z(12 + 10n \quad 41n^{2} + 36n^{3} \quad 9n^{4})^{2}K^{4} + 16zn(2 \quad n)(7 \quad 18n + 9n^{2})^{4}K^{4} \quad 32z_{2}n(2 \quad n)(1 \quad 4n + 2n^{2})^{4}K^{4} + O(K^{5})$$
 (28)

Charge susceptibility:

$${}^{1} c = \frac{1}{2}n(2 - n) - n^{2}(2 - n)^{2} \left(\frac{3}{8} + 2z^{2}\right)K^{2} + \frac{1}{4}K^{3}$$

$$- \frac{1}{16}(10 - 18n + 9n^{2})K^{4} - z(1 + 6n - 3n^{2})^{2}K^{4}$$

$$8z(7 - 18n + 9n^{2})^{4}K^{4} + 16z_{2}(1 - 4n + 2n^{2})^{4}K^{4} + 0(K^{5})$$
(29)

ACKNOW LEDGM ENTS
