#### Abstract

We show that an extension of the standard BCS Ham iltonian leads to an in nite num ber of condensates w ith di erent energy gaps and self-sim ilar properties, described by a cyclic RG ow of the BCS coupling constant which retums to its original value after a nite RG time.

PACS num bers: 11.10. Hi, $74.20 \mathrm{Fg}, 71.10 \mathrm{Li}$

The Renorm alization $G$ roup ( $R G$ ) continues to be one of the $m$ ost im portant tools for studying the qualitative and quantitative properties ofquantum eld theories and $m$ any-body problem $s$ in $C$ ondensed $M$ atter physics. The em phasis so far has been $m$ ainly on ow stoward xed points in the UV or $\mathbb{R}$. Recently, an entirely novelkind of RG ow has been discovered in a num ber of system $s$ wherein the RG exhibits a cyclic behavior: after a nite RG transform ation the couplings retum to their original values and the cycle repeats itself. $T$ hus if one decreases the size of the system by a speci c factor that depends on the coupling constants, one recovers the in itial system, much like a R ussian doll, or quantum version of the M andelbrot set. Bedaque, H am m er and Van K oldk observed this behavior in a 3 -body ham iltonian of interest in nuclear physics $\left.{ }_{[1]}^{[1]}\right]$. Thism otivated $G$ lazek and $W$ ilson to de ne a very sim ple quantum -m echanical ham iltonian $w$ ith sim ilar properties [1] . In the m eantim e such behavior was proposed for a certain regim e of anisotropic current-current interactions in 2 dim ensional quantum eld theory $\overline{3} \cdot \overline{1}$.
T he m odels in $\left[\begin{array}{ll}1,1 \\ \hline 1\end{array}, \overline{2}\right]$ are problem $s$ in zero-dim ensional quantum $m$ echanics, and are thus considerably sim pler than the quantum eld theory in $\left[\begin{array}{l}1 \\ ]\end{array}\right]$. In the latter, standard quantum eld theory $m$ ethods of the renorm alization group were used, how ever know ledge of the beta function to all orders $w$ as necessary to observe the cyclic ow . W hat is som ew hat surprising is that the model considered in [3] is not very exotic, and is in fact a wellknow $n$ theory that arises in $m$ any physical problem s: at one-loop it is nothing $m$ ore than the fam ous $K$ osterlitzThouless RG ow, where the cyclic regim e corresponds to $\dot{j}_{\text {? }} j>\dot{g}_{\mathrm{k}} j$. This motivated us to nd a simpler $m$ any-body problem that captures the essential features of the cyclicRG behavior. $W$ e found that a sim ple extension of the BCS ham iltonian has the desirable properties. N am ely, ourm odel is based on the BCS ham iltonian with scattering potential $V_{j j^{\circ}}$ equal to $g+i$ for $"_{j}>{ }_{j o}$ and $g \quad i$ for $"_{j}<{ }_{j}{ }^{\circ}$ in units of the energy spacing .
$T$ he $m$ ain features of the spectrum are the follow ing. For large system size, there are an in nite num ber of BCS condensates, each characterized by an energy gap
$n$ which depends on $g$, . The role of these $m$ any condensates becom es clearer when we investigate the RG

RG ow possesses jum ps from $g=+1$ to $g=1$ and a new cycle begins. Let $L=e{ }^{s} L_{0}$ denote the RG scale, which in our problem corresponds to N the number of unperturbed energy levels, and the period of an RG cycle: $g(e \quad L)=g(L) . W$ e show that $==$.

The model we shall consider is an extension of the reduced BCS m odel used to describe ultrasm all superconducting grains $\left[\frac{4}{4}\right]$, although our results are valid for m ore general cases. Let $c_{j}^{y}$; $\left(c_{j} ;\right)$ denote creationannihilation operators for electrons in tim e reversalstates $j$ i. The index $j=1 ;: ; \mathrm{N}$ refers to N equally spaced energy levels $"_{j}$ w th $!<"_{j}<!$. The energy $"_{j}$ represents the energy of a pair of electrons in a given level. The level spacing $w$ ill be denoted 2 , i.e. ${ }_{j+1} \quad "_{j}=2$, so that $!=N$ is tw ige the $D$ ebye energy. The energies in this paper are tw ige their standard values $\left.{ }_{5}^{1}\right]$. Let $b_{j}=C_{j} ; c_{j ;+}, b_{j}^{y}=c_{j ;+}^{y} c_{j ;}^{y}$ denote the usual Cooperpair operators. The H ilbert space $H_{N}$ is spanned by the com bination ofem pty and occupied states. A thalf-ling the dim ension of the H ilbert space is the com binatorial num ber $\mathrm{C}_{\mathrm{N}=2}^{\mathrm{N}}$.

O urm odel is de ned by the reduced BCS ham iltonian

$$
\begin{equation*}
H=\sum_{j=1}^{X_{j}^{N}} "_{j} b_{j}^{y} b_{j} \quad X_{j ; j^{0}=1}^{N_{j}} V_{j j^{0}} b_{j}^{y} b_{j 0} ; \tag{1}
\end{equation*}
$$

$w$ here $\mathrm{V}_{\mathrm{j} j^{\circ}}$ is the scattering potential. In the usualBCS m odel, $\mathrm{V}_{\mathrm{j} j}{ }^{\circ}$ is taken to be a constant. H ere we add an im aginary part which breaks tim e reversal,

$$
V_{j j^{0}}=\begin{array}{lll}
<G+i & \text { if } "_{j}>"_{j^{0}}  \tag{2}\\
: & \text { if } "_{j}="_{j^{0}} ; & G=g \\
G & i & \text { if } "_{j}<"_{j^{0}}
\end{array}
$$

$T$ his ham iltonian is herm itian since $V_{j j^{0}}=V_{j^{0} j}$. W e consider the positive dim ensionless couplings $g$ and
$T$ he BCS variationalansatz for this $m$ odel is

$$
\begin{equation*}
j_{\text {BCS }} i=\sum_{j=1}^{Y^{\mathrm{j}}} u_{j}+v_{j} b_{j}^{y} \quad j 0 i: \tag{3}
\end{equation*}
$$

The $m$ ean- eld treatm ent yields the well-known equations

$$
\begin{array}{ll}
u_{j}^{2}=\frac{1}{2} 1+\frac{j}{E_{j}} ; & v_{j}^{2}=\frac{1}{2} e^{2 i} i_{j} \\
E_{j}=\frac{j}{E_{j}} ;  \tag{4}\\
{ }_{j}^{2}+{ }_{j}^{2} ; & \quad{ }_{j}="_{j} \quad
\end{array}
$$

where $j$ and $j$ satisfy the gap equation:

$$
\begin{equation*}
e_{j}=\underbrace{X}_{j^{0} \notin j} V_{j j^{0}} \frac{e_{j^{0}}}{E_{j^{0}}} ; \quad e_{j} \quad j^{i{ }^{i}}: \tag{5}
\end{equation*}
$$

The chem ical potential equation in our case is satis ed w th $=0$. In the therm odynam ic $\lim$ it, $\mathrm{N}!1$ and
 integrals ${ }^{\text {n }}$ ! $d "=2$. The gap equation tums into
where $e^{(")}=()^{i(")}$.
D i erentiating ( $\left.{ }_{(6)}^{\mathbf{6}}\right)$ w ith respect to " yields

$$
\begin{equation*}
\frac{d}{d^{\prime \prime}}=\frac{}{E(")} ; \tag{7}
\end{equation*}
$$

and the condition that $(")=$ is independent of ". T he solution to eq. $\left(\bar{T}_{1}\right)$ can be taken to be

$$
\begin{equation*}
(")=\sinh ^{1}-: \tag{8}
\end{equation*}
$$

$$
\begin{equation*}
\left.1=\int_{0}^{Z}(!) \frac{d}{}(g \cos +\sin )=\right) \tan (!)=\frac{-}{g}: \tag{9}
\end{equation*}
$$

Solving eq. $(\underline{\underline{q}})$ for the gap yields an in nite num ber of solutions $n$. They can be param eterized as follow s:

$$
\begin{equation*}
{ }_{n}=\frac{!}{\sinh t_{n}} ; \quad t_{n}=t_{0}+\frac{n}{} ; \quad n=0 ; 1 ; 2 ;::: ; \tag{10}
\end{equation*}
$$

$w$ here $t_{0}$ is the principal solution to the equation

$$
\begin{equation*}
\tan \left(t_{0}\right)=\frac{-}{g} ; \quad 0<t_{0}<\frac{}{2}: \tag{11}
\end{equation*}
$$

The gaps satisfy $0>{ }_{1}>\quad$. Each gapprepresents a di erent BCS eigenstate $j_{\mathrm{BCS}}^{(\mathrm{n})} \mathrm{i}$. O ne can show that $\eta_{B C S}^{(n)} j_{B C S}^{\left(n^{0}\right)} i j<\exp N\left(n \quad n^{0}\right)^{2}=8!^{2}$, in the lim it where $n \quad$ !. Thus in the large N lim it, these eigenstates are orthogonal and should all appear in the spectrum, together w ith the usual quasi-particle excitationsabove them. In the lim it ! 0 the gaps $n>0!0$, and since $t_{0}=1=g, 0 \quad 2!e^{1=g}$, in the weak coupling regim $e$, recovering the standard BCS result.

For weak coupling models $n$ !, all the gaps are related by a scale transform ation $n \quad 2 N \quad e^{t_{0}} n=$. Therefore, de ning the condensation energy of the $n$-th BCS eigenstate as $E_{C}^{(n)}=h{ }_{B C S}^{(n)} \mathcal{H}^{(n)}{ }_{B C S}^{(n)} \quad E_{F S}$ we get

$$
\begin{equation*}
E_{C}^{(n)} \quad \frac{n_{n}^{2}}{8} \Rightarrow \quad E_{C}^{(n)} \quad \frac{1}{2} N^{2} e^{2 t_{0} \quad 2 n=}: \tag{12}
\end{equation*}
$$

$T$ hus the spectrum of condensation energies re ects the scaling behavior of the gaps.

N ext we derive RG equations for our model. Let $g_{N}$, ${ }_{N}$ denote the couplings for the ham iltonian $H_{N}$ w ith N energy levels. The idea behind the RG $m$ ethod is to derive an e ective ham iltonian $H_{N} \quad 1$ depending on renorm alized couplings $g_{N} 1_{1} N_{1}$ by integrating out the highest energy levels ${ }_{N}$ or $"_{1}$. This can be accom plished by a canonicaltransform ation, which is form ally analogous to the one used to derive the $t \mathrm{~J} m$ odel from the $H$ ubbard $m$ odel at strong coupling [i]
$W$ e perform the calculation for general $V$. The integration of the level " N yields

$$
\begin{equation*}
\left.V_{j j^{0}}^{(\mathbb{N}} 11\right)=V_{j j^{0}}^{(\mathbb{N})}+\frac{1}{2} V_{j N}^{(\mathbb{N})} V_{N j^{0}}^{(\mathbb{N})} \frac{1}{N}+\frac{1}{N} ; \tag{13}
\end{equation*}
$$

where ${ }_{j}="_{j} \quad V_{j j}$. Integration of the level $"_{1}$ gives the sam e eq. (13 $3_{-}^{\prime}$ ) w ith the replacem ent $\mathrm{n} \quad j$ ! $1+{ }_{j}$.

Specializing to the potentialeq. ( $\overline{\text { z }}$ ) and approxim ating $"_{N} \quad "_{j}$ or $\quad "_{1}+"_{j}$ by $!=N$, the above equation im plies

$$
\begin{equation*}
g_{N} \quad 1=g_{N}+\frac{1}{N}\left(g_{N}^{2}+{\underset{N}{2}}_{2}\right) ; \quad{ }_{N} \quad 1={ }_{N}: \tag{14}
\end{equation*}
$$

Thus is unrenorm alized.
In the large $N$ lim it one can de ne a variable $s=$ $\log \mathrm{N}_{0}=\mathrm{N}$, where $\mathrm{N}_{0}$ is the initial size of the system. T hen the beta function reads

$$
\begin{equation*}
\frac{d g}{d s}=\left(g^{2}+{ }^{2}\right) ; \quad s \quad \log \frac{N_{0}}{N}: \tag{15}
\end{equation*}
$$

The solution to the above equation is

$$
\begin{equation*}
g(\mathrm{~s})=\tan ^{\mathrm{h}} \mathrm{~s}+\tan ^{1} \underline{g}_{0}^{i} ; g_{0}=\mathrm{g}\left(\mathbb{N}_{0}\right): \tag{16}
\end{equation*}
$$

Them ain features of this RG ow are the cyclicity

$$
g(s+\quad)=g(s) \quad() \quad g(e \quad N)=g(\mathbb{N}) ; \quad-; \quad \text { (17) }
$$

and the jum ps from +1 to 1 ,when reducing the size.
The cyclicity of the RG has some im portant im plications for the spectrum. Let $\mathrm{fE}(\mathrm{g} ; ~ ; \mathrm{N}) \mathrm{g}$ denote the energy spectrum of the ham iltonian $H_{N}$. The RG analysis im plies we can com pute this spectrum using the ham iltonian $H_{N} \circ\left(g\left(N^{0}\right)\right)$ if $g\left(N^{0}\right)$ is related to $g(N)$ according the RG equation (1]). M oreover, if $N^{0}$ and $N$ are related by one RG cycle, $N^{0}=e \quad N$, then $g\left(\mathbb{N}^{0}\right)=g(\mathbb{N})$. $T$ hus a plot of the spectrum $f E(g ; ~ ; N) g$ as a function of $N$ but at $x e d g$, is expected to reveal the cyclicity $\mathrm{fE}(\mathrm{g} ; ~ ; \mathrm{e} \mathrm{N}) \mathrm{g}=\mathrm{fE}(\mathrm{g} ; ~ ; \mathrm{N}) \mathrm{g}$. SinceourRG procedure is not exact, we expect to observe this signature w ithin the range of our approxim ations, i.e. for $\ddagger j$ ! . Indeed, this agrees w ith the result show $n$ in eq. (12는). This can also be observed in $g .1$ for the one Cooper pair case, w th the cyclicity given by $1=2$ (see below).
$E$ lim inating $g_{0}$ in eq. (1-1) in term $s$ of the $m$ ean- eld solution, eqs. (19) , we observe that the jum ps in $g(s)$ from +1 to 1 occur at scales $s=\hbar_{1}$. A $s N$ decreases,
$g$ increases steadily to +1 and then jumps to 1 . At $g=+1, t_{0}=0, t_{1}=\quad ;:::$, whereas for $g_{2}=1$, $t_{0}=, t=2=;:::$ P lugging this into eq. (19), one readily sees that

$$
\begin{align*}
0(g=+1) & =1 \\
n+1(g=+1) & =n(g=1) ; \tag{18}
\end{align*}
$$

which indicates that at every jum $p$ the low est condensate disappears from the spectrum, since $\mathrm{E}_{\mathrm{C}}{ }^{(0)}(\mathrm{g}=+1)=$

1 . Eq. (1- $(\overline{1})$ im plies, for the rem aining condensates, $E_{C}^{(n+1)}(g=+1)=E_{C_{C}}^{(n)}(g=1)$. This result is in agreem ent with eq. (12). Therefore, the condensate $j_{B C S}^{(n+1)}$ i of one RG cycle plays the same role as $j_{B C S}^{(n)} i$ of the next cycle.

The blow up of 0 and $E_{C}^{(0)}$ at $g=+1$ is an artifact of the RG scheme used here, since we can only trust the RG for energies below the cuto !. H ow ever the disappearance of bound states is correctly described by this RG (see the one C ooper pair problem for a m ore detailed discussion).
$W$ hen $N=1$ the in nite num ber of condensates are allexpected to appear in the spectrum. H ow ever at nite $N$ this is not possible since the Hibert space is nite dim ensional. O ne can use the RG to estim ate the num ber of condensates $n_{C}$ in the spectrum as a function of $N$. From the discussion above a condensate disappears from the spectrum for each RG cycle. T hus $n_{C}$ should sim ply correspond to the num ber of cycles in $\log \mathrm{N}$ :

$$
\begin{equation*}
\mathrm{n}_{\mathrm{C}} \quad-\log \mathrm{N}: \tag{19}
\end{equation*}
$$

So farwe have found a close relationship betw een the spectrum of our extended BCS ham iltonian in the $m$ eaneld approxim ation and the RG ow of the coupling constants. In order to get a further con $m$ ation of our results we should compute the spectrum for a nite size system. H ow ever, it is very di cult to reach interm ediate sizes for this $m$ odel num erically, since the dim ension of the H ilbert space grow s as $2^{\mathrm{N}}=\mathrm{N}^{1=2}$. Fortunately, to this end, the sim ilarities between the $m$ any-body case and the case of one C opper pair, in the presence of the Ferm i sea, are widely known.

For one C ooper pair in the presence of the Ferm i sea, consider an eigenstate of the form ji= j j $b_{j}^{y} j \mathrm{Di}$. The Schrodinger equation reads

$$
\left(\begin{array}{ll}
{ }_{j} & E
\end{array}\right)_{j}=G_{j}+(G+i)_{l<j}^{X} \quad{ }_{1}+\left(\begin{array}{ll}
G & i
\end{array}\right)_{l>j}^{X} \quad{ }_{l} ;(20)
$$

with " ${ }_{j} 2(0 ;!)$, i.e. the Ferm isea is not accessjble for the pair. Then, in the large N lim it, the sums ${ }_{\mathrm{R}}$ are the pair. Then, in the large $N$ lim 代, the
replaced by integrals ${ }_{0} d$ " $=2$, leading to

D i erentiating the above with respect to " and integrating, one obtains

$$
\begin{equation*}
\text { (") } \frac{1}{" E} e^{i \log (" E)} \text { : } \tag{22}
\end{equation*}
$$

This wave function does not have cuts in two cases, i) $\mathrm{E}<0$ and ii) $\mathrm{E}>$ !. C ase i) corresponds to the usual C opper pair problem where one is looking forbound state solutions (these are the solutions we claim to have a sim ilar behavior to the $m$ any-body case). P lugging eq. (22) back into eq. (2121) one nds

$$
\begin{equation*}
\frac{g+i}{g i}=1 \frac{!}{E}^{i}: \tag{23}
\end{equation*}
$$

$T$ his equation has an in nite num ber of solutions given by

$$
\begin{equation*}
E_{n}=\frac{!}{e^{t_{n}}} ; \quad t_{n}=t_{0}+\frac{2 n}{n} ; \quad \text { n } 2 \mathrm{z} ; \tag{24}
\end{equation*}
$$

where $t_{0}$ is the principal solution to the equation

$$
\begin{equation*}
\tan \frac{1}{2} t_{0}=\frac{-}{g} ; \quad 0<t_{0}<-: \tag{25}
\end{equation*}
$$

Then 0 solutions correspond to $\mathrm{E}_{\mathrm{n}}<0$, while those w ith $\mathrm{n}<0$ yield $\mathrm{E}_{\mathrm{n}}>$ !.

A s for the $m$ any-body case the spectrum has a scaling behavior for weak coupling system s, nam ely

$$
\begin{equation*}
\mathrm{E}_{\mathrm{n}} \quad \mathrm{~N} \quad \mathrm{e}^{\mathrm{t}_{0}} 2 \mathrm{n}=: \tag{26}
\end{equation*}
$$

An RG analysis sim ilar to the one in the $m$ any-body problem leads to the equation

$$
\begin{equation*}
g_{N} \quad 2=g_{N}+\frac{g_{N}^{2}+{\underset{N}{N}}_{2}^{N} 1 \quad g}{N} \quad \quad \quad{ }_{N} \quad 1={ }_{N} ; \tag{27}
\end{equation*}
$$

which in the large $N$ lim it becom es

$$
\begin{equation*}
\frac{\mathrm{dg}}{\mathrm{ds}}=\frac{1}{2}\left(g^{2}+{ }^{2}\right): \tag{28}
\end{equation*}
$$

The solution to this equation is given by eq. (1-1 ${ }^{-1}$ ) just by replacing $s!s=2$. This im plies that the period of the cyclicity in $s=\log \mathrm{N}_{0}=\mathrm{N}$ is $1=2=$.

The factor $1=2$ in the above form ulas, as com pared to them any-body problem, com es from the non accessibility of the C ooper pair to the states below the Ferm i level.
$T$ he discussion leading to eq. (1") can be repeated for the one-c ooper pair problem where the role of the $n$-th condensate is played by the $n$-th bound state $w$ th energy $\mathrm{E}_{\mathrm{n}}$ given in eq. (2 $\left.\overline{4}_{1}^{-}\right)$, obtaining

$$
\begin{align*}
\mathrm{E}_{0}(\mathrm{~g}=+1) & =1 \\
\mathrm{E}_{\mathrm{n}+1}(\mathrm{~g}=+1) & =\mathrm{E}_{\mathrm{n}}(\mathrm{~g}=1): \tag{29}
\end{align*}
$$

Thus we expect that in each RG cycle a bound state w ill disappear. The analogue of equation ( $\mathbf{1}^{-1} \underline{9}^{\prime}$ ) is

$$
\begin{equation*}
\mathrm{n}_{\mathrm{B}} \quad \overline{2} \log \frac{\mathrm{~N}}{2} \tag{30}
\end{equation*}
$$

$w$ here $n_{B}$ is the num ber ofbound states in the spectrum.
$T$ his again shows the agreem ent between the $m$ eaneld and the RG results. W e con $m$ bellow this picture w th num erical calculations.

F IG . 1: Exact eigenstates of one-C ooper pair H am iltonian for N levels, from $\mathrm{N}_{0}=500$ down to 50. W e depict only the states nearest to zero. T he vertical lines are at the values $N_{n}=e^{n}{ }^{1} N o . T$ he dotted horizontal lines show the cyclicity of the spectrum.

Fig. 1 show sthe num erical solution of eq. (2d) for $g=$ 1 , $=12$ and N ranging from 500 dow n to 50 . For each $N$ there are $n_{B}(\mathbb{N})$ bound states $E_{n}<0$, where $n_{B}(\mathbb{N})$ is in good agreem ent w th eq. (3]).

The spectrum show s the self-sim ilarity found in the approaches above: scaling the system by a factor e ${ }^{1}$, w th $1=2=$, one recovers the sam e spectrum for sufciently sm all energies, i.e.

$$
\begin{equation*}
\mathrm{E}_{\mathrm{n}+1}(\mathbb{N} ; g ;)=\mathrm{E}_{\mathrm{n}}\left(\mathrm{e}{ }^{1} \mathrm{~N} ; g ;\right): \tag{31}
\end{equation*}
$$

Fig. 1 also show s the existence of critical values $N_{c ; n}$, in the intervals ( $e^{n}{ }^{1} N$; $e^{(n+1)}{ }^{1} N$ ), where the bound state closest to the Ferm i leveldisappears into the \continuum ". This e ect leads to the reshu ing of bound states, $n+1!n$, observed in eq. ( $\overline{31}_{1}^{\prime}$ ). The critical sizes are also related by scaling, ie. $\mathrm{N}_{\mathrm{c} ; \mathrm{n}}=\mathrm{N}_{\mathrm{c} ; \mathrm{n}+1}=\mathrm{e}{ }^{1}$. A ll these phenom ena are in good agreem ent w th the RG interpretation we proposed, where the condensates disappear at scales where $g\left(s=t_{n}\right)=+1$. All these points are related by the scaling factore ${ }^{1}$.

TheRG behavior is presented in $g .2$, which show sthe eigenvalues $\mathrm{E}_{\mathrm{n}}(\mathbb{N})$ of the one-C ooper pair H am iltonian, $w$ ith $g_{N}$ running under eq. ( $2 \overline{7}_{1}^{\prime}$ ). The spectrum rem ains unchanged for $\mathrm{E}_{\mathrm{n}}(\mathbb{N}) \quad \mathrm{N}$, as shown in g .2 b . In g. 2a one observes that for the energies $E_{n}(\mathbb{N})^{>} N$ the result of the RG is not reliable. N evertheless the RG ow describes qualitatively the disappearance of the low est bound state and the reshu ing of energy levels after a cycle, and furthem ore at the predicted scales.

In sum $m$ ary, we have show $n$ that adding to the standard BCS Ham iltonian a tim e reversal breaking term, param etrized by a coupling constant, generates an in nite num ber of condensates $w$ ith energy gaps ${ }_{n}$ related, for weak BCS couplings $g$, by a scale factore $w$ th
$==$. This unusual spectrum is explained by the cyclic behavior of the RG ow of $g$, which reproduces itself after a nite RG times equal to . W e have also solved the nite tem perature BCS gap equation, obtaining a critical tem perature $T_{c ; n}$ for the $n$-th condensate which is related to the zero tem perature gap ${ }_{n}(0)$ exactly as in the BCS theory, i.e. $n(0)=T_{c ; n}=3: 52$ for weak couplings.

The sim plicity of the $m$ odelproposed in this letter suggests that Russian doll superconductors could perhaps be realized experim entally. Finally, we point out that the critical tem perature can be raised by varying .

F IG . 2: E igenstates of one-C ooper pair $H$ am iltonian $w$ ith $g_{N}$ given by eq. (271) w ith $g_{0}=1$ and $=12$. The vertical lines denote the positions at which $g$ jumps from +1 to 1 .
