#### Abstract

W e establish a general fram ew ork to explore param etric statistics of individual energy levels in unitary random $m$ atrix ensembles. For a generic con nem ent potential $W$ ( H ), we (i) nd the joint distribution functions of the eigenvalues of $H$ and $H^{0}=H+V$ for an arbitrary xed $V$ both for nite $m$ atrix size $N$ and in the \therm odynam ic" $N$ ! 1 lim it; (ii) derive $m$ anypoint param etric correlation functions of the two sets of eigenvalues and show that they are naturally param etrised by the eigenvalues of the reactance $m$ atrix for scattering o the \potential" V ; (iii) prove the universality of the correlation functions in unitary ensembles w ith non-G aussian non-invariant con nem ent potential $W$ (H V); (iv) establish a general scheme for exact calculation of level-num ber-dependent param etric correlation functions and apply the schem e to the calculation of intra-levelvelocity autocorrelation function and the distribution of param etric level shifts.

## 1. Introduction

$P$ aram eter-dependent evolution of spectra in random $m$ atrix ensembles has been a subject of investigation alm ost from the inception of the $R$ andom $M$ atrix $T h e o r y$ (RMT) [1, 2]. D yson [1] showed that the joint probability distribution function of the eigenvalues in the classic random $m$ atrix ensem bles can be altematively obtained as an equilibrium distribution of a one-dim ensional gas of classical charges which undergo Browninan motion in ctitious time while sim ultaneously logarithm ically repelling each other. T he sam e dynam ics of eigenvalues arises if the corresponding random $m$ atrices them selves execute $B$ rowninan $m$ otion [3] according to a sequence of $m$ appings $H \geqslant H+d V$ where $H$ is drawn form a random $m$ atrix ensemble and $d V$ is the elem entary step of the random walk in the space of $m$ atrices of the sam $e$ symm etry as H.

However, despite the theoretical interest in these types of models, the experim ental motivation in the early days of RM T was lacking since the nuclear spectra for which RMT was originally devised [4] are essentially im mutable. Later, the range of RM T applications has broadened to include system $s$ such as m esoscopic quantum structures (e.g., quantum dots) which can be subject to a variety of extemal perturbations [5]. In fact, controlled extemal perturbations such as magnetic eld
or gate potential often serve as im portant experim ental tools to study statistical properties of such system $s$. Thus, instead of a sequence of random steps dV one is lead to consider nite $m$ appings $H$ I $H^{0}=H+V$, where $V$ is a xed $m$ atrix w ith the sam e sym $m$ etry as the ensem ble from which the $m$ atrices $H$ are draw $n y[6,7,[8,9]$.

W hile $m$ agnetic eld clearly belongs to the class of extended perturbations, in $m$ any applications the assum ption that the rank of $V$ scales $w$ th $N$ may not prove to be adequate in the RM T m odelling ofm esoscopic devices. Extemal perturbations such as an STM tip, a change in the potential on a nger-shaped gate, or a jum pin the position of a bi- or multi-stable defect represent potentials which are localised in space. In the RM T language localised potentials are m odelled by $m$ atrioes $V$ of nite rank $r$. Such $m$ atriees can be represented using a nite set of orthonorm al com plex vectors fa $g^{r}=1$ as $V=N{ }_{=1}^{r} v a \quad a^{y}$. For technical reasons related to the use of the Itzykson \{ Zuber \{ H arish-C handra (Z H C ) integral [10], our consideration here is restricted to the unitary ensem ble, hence the requirem ent that a are complex.]

In the standard RM T one can distinguish two classes of correlation functions betw een the levels [2]. In the rst class the levels are \labelled" by their positions (\energies" in the H am iltonian interpretation of the random $m$ atrioes), so that the fiundam ental op ject is the $m$ any-point correlation function of the density of states

$$
\begin{array}{r}
(\mathrm{D} \circ \mathrm{~S}) \quad(E)={ }_{=1}^{\mathrm{N}} \quad(\mathrm{E}) \prime_{\star} \quad+ \\
\mathrm{R}_{\mathrm{n}}\left(\mathrm{fE} \mathrm{~g}_{\mathrm{i}=1}^{\mathrm{n}}\right)={ }_{\mathrm{Y}}^{\mathrm{n}} \quad\left(\mathrm{E}_{\mathrm{i}}\right) \quad ;
\end{array}
$$

$w$ here the angular brackets denote averaging over the $m$ atrix ensemble. In the bulk region of the spectrum the correlation functions are translationally invariant $w$ ith respect to the sim ultaneous shifts of all energies, so that $\mathrm{R}_{\mathrm{n}}$ is actually a function of n 1 energy di erences. Such correlation functions are know $n$ to have determ inantal structures in all three classic $W$ igner-D yson ensem bles. E .g., in the unitary ensem ble, the N ! 1 lim it results in

$$
\begin{equation*}
\mathrm{R}_{\mathrm{n}}\left(\mathrm{fE}_{\mathrm{i}=1}^{\mathrm{n}}\right)=\operatorname{det}_{\mathrm{ij}} \widetilde{K}\left({ }_{\mathrm{i}} \quad \mathrm{~m}_{j}\right) \tag{2}
\end{equation*}
$$

 sine kemel of the $W$ igner-D yson $R M T$, the dim ensionless energies " $E=$ are norm alised by the $m$ ean levelspacing $=h \quad(E) i^{1} \quad(E)^{1}$, and the step-function
is regularised so that $(0)=0$. The term involving the -function accounts for the self-correlation of levels. A nalogous structures with m ore involved kemels arise in other ensem bles. W hile originally derived in the context of the G aussian Unitary Ensemble (G UE), the correlation kemel $k$ acquires the same universal form in the bulk scaling lim it for a wide class of non-G aussian random $m$ atrix ensem bles [11]

$$
\begin{equation*}
\mathrm{P}(\mathrm{H})=\mathrm{C}_{\mathrm{U}} \mathrm{e}^{\mathrm{TrW}(\mathrm{H})} ; \tag{3}
\end{equation*}
$$

where $W$ ( H ) is an even polynom ial, and $\mathrm{C}_{\mathrm{U}}$ is the nom alisation constant.
In the second class ofcorrelation functions the levels are labelled by their num bers, $w$ hile their energies $m$ ay or $m$ ay not enter as additional variables depending on the speci c correlation function. An archetypal example is the distribution of level spacings $S_{1}(!)$ which is a particular case of the distribution $S_{q}(!)$ of distances between a level and another level separated from by $q 1$ other levels:

$$
\begin{equation*}
S_{q}(!)=h(E) \quad(+q \quad E \quad!) i: \tag{4}
\end{equation*}
$$

y A separate subject which is beyond the scope of this paper concems mappings such that the sym $m$ etry of $V$ is low er than the sym $m$ etry of $H$.
$S_{1}$ is actually a correlation function betw een an arbitrary level and its neighbour +1 . Translationalinvariance in the bulk of the spectrum ensures that this correlation function does not depend on either E or. In contrast with (2) no sum $m$ ation over is involved, so that level-num ber-speci c inform ation is retained, and, indeed, near the edge of the spectrum, the sam e correlation function \{ now as a function of both level num bers \{ describes the distribution of distances betw een, say, the second low est and the third low est levels.
$T$ he two types of the correlation functions are related to each other via in nite series. Thus, an equivalent expression for $S_{1}(!)$ w thout referring to speci c level num bers is the joint probabillty to nd two levels at positions E and E + ! and all other levels in the interval $R=\mathbb{E} ; E+!]$. A fter straightforw ard algebra [2], $S_{1}(!)$ is w ritten as

$$
S_{1}(!)=@_{!}^{2} \sum_{n=0}^{X^{A}} \frac{(1)^{Z}}{n!} e_{E}^{Z+!} d E_{1}:::_{E}^{Z} d E_{n} R_{n}\left(f E_{i} g_{i=1}^{n}\right) ; \text { (5) }
$$

where $R_{n}\left(f E g_{i=1}^{n}\right)=\operatorname{det}_{i j} k\left(E_{i} \quad E_{j}\right)$ is the part of $R_{n}$ from which the level selfcorrelation term $s$ are exchuded. Combined w the determ inantal structure of $R_{n}$, th is form ula allow s one to express $S_{1}$ in term sof the derivative of a certain generating function, $S_{1}=@ \sum_{!}^{2} \operatorname{det}_{\mathbb{E} ; E+!]} I \hat{k}$, where the determ inant is understood as a Fredholm determ inant on the space of functions $w$ ith the support in the interval $\mathbb{E} ; E+!]$, and the kemel $\hat{k}$ is de ned through itsm atrix elem ents: $\hat{k}(u ; w)=k(u \quad w)$. A nalogous expressions can be obtained for other $\mathrm{P}_{\mathrm{q}}$ 's. The Fredholm determ inant itself \{ the generating function \{ is the probability to nd no levels in the interval $\mathbb{E} ; E+!]$. O ther $S_{q}$ 's are sim ilarly related to the Fredholm determ inant expressions for the probability to nd q 1 levels in a given interval.
$C$ onversely, the correlation function $R_{2}(E ; E+!)$ can be expressed as an in nite sum over $S_{q}{ }^{\prime}$ s,

$$
\begin{equation*}
R_{2}(E ; E+!)={ }_{q=1}^{\Lambda} S_{q}(!) \tag{6}
\end{equation*}
$$

which is a simple restatem ent of the fact that the conditional (on the existence of a level atE ) probability to nd any levelat E + ! is the sum overq of the (conditional) probabillties to nd the ( $+q$ ) th level at that position. O perationally, how ever, $R_{n}$ is usually $m$ ore readily accessible than $S q$, so that equation (6) and its analogues are not often used in practical calculations.

In direct analogy w th the duallity betw een the tw o classes of correlation functions described above for ordinary $\mathrm{RM} T$, one can introduce their generalisations in the param etric RM T.Thus, instead of $R_{n}$ we are now lead to de ne the param etric $m$ anypoint correlation function as

$$
\begin{equation*}
R_{n m} \quad f E_{i} g_{i=1}^{n} ; f E_{j}^{0} g_{j=1}^{m}=Y_{i=1}^{*} \quad\left(E_{i}\right)^{Y n} Y_{j=1}^{n} E_{j}^{0} \quad \text {; } \tag{7}
\end{equation*}
$$

where ${ }^{0}(E)=\operatorname{Tr} \quad\left(E \quad H^{0}\right)$.
Except in the $r=1$ case (see below), the \level spacing" in the com bined set $\mathrm{fE} \mathrm{g}\left[\mathrm{fE}{ }^{0} \mathrm{~g}\right.$ does not have an im $m$ ediate physical intenpretation. A $m$ ore $m$ eaningfiul analogue of equation (4) is the distribution of distances between a level and the param etric \descendant" of the level $+q$,

$$
\begin{equation*}
P_{q}(!; x)=h(\quad E) \quad(+q(x) \quad E \quad!) i ; \tag{8}
\end{equation*}
$$

$w$ here x is the set of the param eters characterising V . D ue to universality [ $\mathbb{1}, 12], \mathrm{x}$ can be identi ed w th either a single param eter $\mathrm{x} m$ easuring the overall strength of $V$ in the case of extended (in nite rank) perturbations, or $w$ ith a set of at $m$ ost $r$ param eters in the nite rank case (see Section 3). $\mathrm{P}_{0}$ is simply the distribution of shifts of a single level under the in uence of a param etric perturbation. N ote the absence of sum $m$ ation over ; nevertheless, in the bulk of the spectrum $P_{q}$ is not a function of .

A related quantity which in the past has been extensively studied in the context of param etric correlations in chaotic and disordered system susing either num erical or approxim ate analytical techniques [13, 7, 14, 15, 16] is the single level velocity correlation function $C_{0}(x) . W$ ithin the form alism developed in the present paper, it is convenient to represent it as a special case of the follow ing correlation function:

$$
\begin{equation*}
C_{q}(x)=h @_{x} \quad(x=0) @_{x}+q(x) i ; \tag{9}
\end{equation*}
$$

which represents the correlation of responses to the perturbation of two levels separated by a distance $x$ in the param eter space, and by $q \quad 1$ levels in the level sequence.

The ob jective of this paper is to present a set of interrelated developm ents in the param etric RM T. In the next section we construct a form alism to determ ine the joint distribution functions for the eigenvalues of $H$ and $H{ }^{0}$ for perturbing $m$ atrioes $V$ of arbitrary rank $r$. In particular, we concentrate on the case when $r$ is nite in the N ! 1 lm it, although the results are equally applicable in the opposite lim it where we reproduce the $G$ aussian transition kemelim plicit in the earlier w ork on the sub ject [7, 18].

In Section 3.1 we use the joint distribution functions to derive the $m$ any-point correlation function $R_{n m}$. $W$ e show that the latter possesses the determ inantal structure at arbitrary r [17], generalizing the result previously known only in the context of twom atrix models [7, 18] (i.e., $w$ ith $V$ itself draw $n$ from a random $m$ atrix ensemble), and thus corresponding to $r=N$ in the classi cation adopted here. In Section 32 these results are applied to prove (on a physical level of rigour) that the universality of the $W$ igner-D yson sine kemel extends to a class of non-invariant ensembles characterised by the distribution function $P_{V}(H)=$ $C_{U} \exp f \quad \operatorname{TrW} \quad(H \quad V) g$.

The nal ob jective of this paper is to present (Section 3.3) a general fram ew ork for the calculation of $\mathrm{P}_{\mathrm{q}}(!; \mathrm{x}), \mathrm{C}_{\mathrm{q}}(\mathrm{x})$, and related num ber-dependent correlation functions in term $s$ of the corresponding fam ily of generating functions. Ow ing to the determ inantal structure of $\mathrm{R}_{\mathrm{nm}}$ [17, 7, [18] (see also Section 3.1 below), the latter possess representations in term sofF redholm determ inants of certain param eterdependent integral kemels.
2. Joint $D$ istributions of $E$ igenvalues

C onsider a set of pairs of $m$ atrices $H$ and $H^{0}=H+V$, with $H$ being a random Hem itian $N \quad N$ matrix $H$ drawn from the unitary ensemble $P(H)$ and $V$ is a determ inistic $m$ atrix of rank $r$. The joint distribution of the $m$ atrices $H$ and $H^{0}$ is

$$
\begin{equation*}
\mathrm{P}\left(\mathrm{H} ; \mathrm{H}^{0}\right)=\mathrm{P}(\mathrm{H}) \quad\left(\mathrm{H}+\mathrm{V} \quad \mathrm{H}^{0}\right) ; \tag{10}
\end{equation*}
$$

where the $m$ atrix delta-fiunction is understood as the product of ordinary scalar deltafunctions \{ one per each of the $\mathrm{N}^{2}$ independent variables of H. The joint distribution
function of the com bined set of eigenvalues $f \quad g^{N}=1$ of the $m$ atrix $H$ and $n_{=1}^{O_{N}}$ of $H^{0}$ is obtained from the above expression by integrating out the angular degrees of freedom :

$$
\begin{equation*}
P\left(f g ; f^{0} g\right)={ }^{2}(H) \quad{ }^{2}\left(H^{0}\right) d \quad(U) d \quad\left(U^{0}\right) P\left(H ; H^{0}\right) ; \tag{11}
\end{equation*}
$$

where d (U) is the invariant H aarm easure on the unitary group $U(\mathbb{N})$, and $(H)$ is the Vanderm onde determ inant

$$
\begin{equation*}
(\mathrm{H}) \quad(\mathrm{f} \mathrm{~g})=\mathrm{Y}_{1} \mathrm{C}_{\mathrm{N}}(\quad): \tag{12}
\end{equation*}
$$

$W$ th the help of a Lagrange $m$ ultiplier matrix (it is straightforw ard to show that independent com ponents of can be arranged into a H erm itian $m$ atrix) the expression for the joint distribution function takes the form

$$
\begin{align*}
& \exp \operatorname{fiTr}\left(H+V \quad H^{0}\right) g \exp f W(H) g ; \tag{13}
\end{align*}
$$

where $k$ are the eigenvalues of. Integration over the angular degrees of freedom of H and $\mathrm{H}^{0}$ can be perform ed w th the help of the $\mathbb{Z} H C$ integral (10)

$$
\begin{equation*}
d(U) \exp i \operatorname{TrABU} U^{y}=c \frac{\operatorname{det} \quad[\exp (\text { ia b })]}{(A)(B)} ; \tag{14}
\end{equation*}
$$

where fa $g^{N}=1$, fb $g^{N}=1$ are the com plete sets of the eigenvalues of the $m$ atrices $A$ and $B$, respectively, and $\left.C=(i=2)^{\left(N^{2} N\right.}\right)_{j=2}^{N}{ }_{j=1} j!$. The rem aining integral thus takes the form

where the sum over runs over all perm utations of the indioes $1 ;::: ; \mathrm{N}$, and (1) denotes the signature of the perm utation. The ordering of the energy levels in the Vanderm onde determ inants is assum ed to be in the increasing order. D ue to the invariance of the $m$ easure ( $U$ ), the integralin (15) does not depend on the \angular" degrees of freedom of $V$. The latter can thus be thought of as \gauge" degrees of freedom of (15), and integrated over $w$ th an appropriate $m$ easure $d$ (r) (fa g). A convenient choice for $d_{(r)}$ (fa $g$ ) is the uniform distribution of all com ponents of a constrained only by the requirem ent of orthonorm ality. U rotations can now be absorbed into the rotations of $V$, and the integral over d (U ) gives a constant $N_{N}=R^{R}(U)=(2)^{\left(N^{2} N\right)=2} \sum_{\substack{N \\ j=1}} j!$. Equation (15) can now be rew ritten as

$$
\left.P\left(f g ; f^{0} g\right)=\frac{C_{U} \dot{J} \mathcal{C}^{2} N_{N}}{(2)^{N^{2}} N_{N}} e^{P_{N}=1 W()} \text { (H) (H }{ }^{0}\right)
$$

Z
$\mathrm{d}_{\text {(r) }}(\mathrm{fa} \mathrm{g}) \operatorname{det} \quad 0 \mathrm{~V}$;
where $V$ are the diagonal elem ents of $V=N \quad{ }^{P}{ }_{r=1} V \quad$ a $\quad a^{y}$. It is worth noting at this point that if integrating over $d_{(r)}(f a \mathrm{~g})$ does not introduce correlations betw een $V$, the distribution finction acquires, apart from the asym $m$ etry introduced by the con ning potential, a form rem iniscent of a quantum $m$ echanical transition am plitude: the Vanderm onde determ inants play the role of Slater determ inants describing antisym $m$ etric $m$ any-ferm ion $w$ ave fiunctions, and the determ inantal form of the transition kemelim plies that the ferm ions are non-interacting albeit subject to an unusualsingle-particle $H$ am iltonian. C orrelationsbetw een $V$ then im ply interactions betw een the particles.

W e now analyse several lim iting cases. IfV itself is draw n from a unitary random $m$ atrix ensemble $P(V) / e^{T r r v^{2}=2 X^{2}}$ (and is thus of rank $r=N$ ), the integration over \& (N) $\left(f a_{Q} g\right)$ is subsum ed into the integration over $V$. In \C artesian" coordinates
$d V \quad<d<V \quad d=V$ the $m$ atrix elem ents $V$ are explicitly uncorrelated and independently $G$ aussian distributed. The transition kemel is thus proportional to det $\left.e^{x^{2}( }{ }^{0}\right)^{2}=2$, corresponding to free propagation of the ordinary onedim ensional ferm ions in the quantum -m echanical analogy (w th $X^{2}$ playing the role of im aginary time). An identical joint distribution arises also in the study of onedim ensional non-intersecting random walkers [19].

Retuming to the case of $x e d V$, and still considering $r \quad N$, we note that the $\mathrm{N}^{2} \mathrm{~N}$ \gauge degrees of freedom " of V enter only through N combinations V . An application of the centrallim it theorem then im plies that, after integrating the \gauge degrees of freedom " out, $V$ becom e independently distributed $w$ th the $G$ aussian weight $\exp \quad N^{2} V^{2}=2 \mathrm{Tr}^{2}$. C onsequently, the form of the kemel coincides $w$ ith the case when $V$ is random.

Let us tum now to the case when $r \quad O$ (1). The rem aining step in the derivation of the joint distribution function of the eigenvalues is to im plem ent the integration over $d_{(r)}(f a g)$. This can be done in two ways which lead to di erent form $s$ of the distribution functions but are ultim ately equivalent in the $N$ ! 1 lim it when applied to the calculation of the correlation functions. The rst \{ exact \{ procedure requires enforcing the conditions of orthonorm ality betw een the $r$ com plex vectors a . A though quite simple in the $r=1$ case, already for $r=2$ it leads to a som ew hat lengthy calculation, as we will show below, and it quickly becom es unm anageable for larger values ofr. If, how ever, the ultim ate interest is in the correlation functions $\mathrm{R}_{\mathrm{nm}}$ in which the scaling lim it N ! 1 is taken at xed values of $n$ and $m$, integrating out the rem aining $2 \mathrm{~N} \quad \mathrm{n} \quad \mathrm{m}$ \energies" leaves the correlation function dependent only on a nite number of com ponents a of the r vectors a. A ccording to a well-known result in RM T [2] , the latter are distributed independently according to the P orterThom as form ula e ${ }^{\mathrm{N} j \mathrm{j}} \mathrm{j}^{2}$. The distribution functions obtained by replacing the whole ofd (r) (fa g) w th the product of independent P orter-T hom as distributions for each of the N r com ponents of a can be intenpreted as resulting from the substitution of a \canonical" ensem ble for the gas of levels in place of the \m icro-canonical" ensem ble im plied by the identity $\operatorname{TrH}{ }^{0}=\operatorname{Tr}(\mathrm{H}+\mathrm{V})$.

### 2.1. Exact ( $\backslash \mathrm{m}$ icro-canonical") joint distribution functions

To illustrate the $m$ ethod, let us rst consider the $r=1$ case. $T$ he corresponding distribution function and the low est-order nontrivial correlation function ( $\mathrm{R}_{11}$ in our notation) have been derived using a som ew hat di erent approach in Ref. 21]. V is param etrised as vN a $a^{\mathrm{y}}$, and for a single nom alised com plex vector a the $m$ easure
d (1) (a) becom es

$$
\begin{equation*}
d_{\text {(1) }}(a)=J_{1} \quad a^{y} a \quad 1 e^{a^{y} a} d[a] \tag{17}
\end{equation*}
$$

where d [a] denotes the unconstrained $m$ easure ${ }^{Q_{N}}$ da da $=$, and is a positive in nitesim alintroduced for convergence. The norm alisation constant $J_{1}$ is determ ined from
$1=J_{1} \quad d[a]{ }_{1}^{Z} \frac{d x}{2} e^{i x}$ i(x i) $a^{y} a=J_{1} Z_{1} \frac{d x}{2} \frac{e^{i x}}{(i x+)^{N}}=\frac{J_{1}}{(N \quad 1)!}$ :
Substituting this m easure into (16) we obtain

$$
\begin{align*}
& 0_{0} \mathrm{X} \quad \mathrm{X} \\
& 1 \\
& N V^{A} \operatorname{det} \operatorname{Sign} v 0: \tag{19}
\end{align*}
$$

A s expected [21], the determ inant is nonzero only if the tw o sets of levels satisfy the \interleaved combs" constraint $<0<+1$ for $v>0$ and $1<0<$ for $\mathrm{v}<0$.

W e next consider the $r=2$ case. It is conven ient to use a sym m etrised expression $\mathrm{V}=\mathrm{vN} \mathrm{a} \quad \mathrm{a}^{\mathrm{V}} \mathrm{b} \quad \mathrm{B}$ where a and b are two com plex mutually orthogonalN com ponent vectors of length 1 , and $v$ is the scalar (positive) param eter characterising the $m$ agnitude ofV. M ore generalexpressions can be reduced to this form by a sim ple rescaling in the nal results. It is also convenient to re-exponentiate the -functions in the determ inant in (16) so that the integrals are perform ed at a later stage in the calculation. Them easure $d{ }_{(2)}(a ; b)$ is explicitly param etrised as

$$
\begin{equation*}
d_{(2)}(a ; b)=J_{2} d[a] d[b] \quad(a ; b) e^{\left(a^{y} a+b^{y} b\right)} \tag{20}
\end{equation*}
$$

where ( $\mathrm{a} ; \mathrm{b}$ ) stands for

$$
\begin{equation*}
a^{y} a \quad 1 \quad b^{y} b \quad 1 \quad a^{y} b+b^{y} a \quad \frac{1}{i} a^{y} b \quad b^{y} a \quad ; \tag{21}
\end{equation*}
$$

and $J_{2}$ is the nom alisation constant. To com pute $J_{2}$, the delta-functions are exponentiated w ith the help of two real Lagrange $m$ ultipliers $x$ and $y$, and a com plex

$$
\begin{aligned}
& \text { Lagrange } m \text { ultiplier } z \text { : } \\
& 1=J_{2} \quad \text { [da] [db] }(a ; b) \exp \quad a^{y} a+b^{y} b \quad=J_{2} \quad \frac{d x d y d<z d=z}{(2)^{4}} \text { [da] [db] } \\
& \exp i(x \quad i) 1 \quad a^{y} a+i(y \quad i) 1 \quad b^{y} b \quad i z a^{y} b \quad i z b^{y} a \quad:
\end{aligned}
$$

Perform ing the integrals, we nd

$$
\mathrm{J}_{2}=4 \quad \underline{2}^{2 \mathrm{~N}}\left(\begin{array}{llll}
1)^{\mathrm{N}} & (\mathbb{N} & 1)!(\mathbb{N} & 2)! \tag{22}
\end{array}\right.
$$

W ith these de nitions, we have

P roceeding as in the com putation of $J_{2}$, we obtain

$$
\begin{aligned}
& \left.P\left(f g ; f{ }^{0} g\right)=\frac{C_{U} j_{2} j \dot{j} \mathcal{C l}^{2}}{(2)^{N^{2}}} \quad \text { (H) (H } \quad{ }^{0}\right) \quad \frac{2^{2}}{N V} \quad \frac{d x d y d<z d=z}{(2)^{4}} e^{i(x+y)}
\end{aligned}
$$

A fter integrating out the eigenvalues of we obtain

where $=x \quad y, t=x+y$, $=2 \dot{z j} s \quad$ Signt, the ambiguities in the analytic properties of the integrand are resolved by letting $t!t i$, and $=$ $\begin{array}{ll}\mathrm{P}_{\mathrm{N}}=1 & 0 \\ (,)\end{array}=2 \mathrm{~N} \mathrm{~V}$. The extra factor N ! com es from perform ing one of the sum S over perm utations. $N$ ote that the param eter depends only on the absolute values of the distances betw een the levels in contrast to the case of rank $r=1$ perturbation [21].

Integration over gives a factor of $4 \mathrm{~N} v{ }^{\mathrm{P}}\left[\quad\left(\quad{ }^{0}\right)\right]$ which sim ply enforces the identity $\operatorname{TrH}=\operatorname{TrH}^{0}$. Perform ing the rem aining integrations, we nd

$$
(H) \quad\left(H^{0}\right) e^{P_{N}^{N} W}()^{X} \quad\left(\begin{array}{l}
1)
\end{array}(1 \quad)(1 \quad)^{N}{ }^{2}:(25)\right.
$$

Note the hard constraint on the sum of the absolute values of the level shifts ( ) 2 N v . N ote also that this result cannot be sim pli ed in an obvious
 $v$ is the $m$ ean level spacing, and $P \quad 0^{0}() \quad O(\mathbb{N})$ so that the $\quad 0$ (1). The distribution functions (16) and (27) below are equivalent only in the sense that they lead to identical correlation functions in the \therm odynam ic" lim it N ! 1 .

## 2.2. \C anonical" joint distributions

A s discussed above, after neglecting $\mathrm{O}(1=\mathrm{N})$ corrections, the $m$ easure $d$ (r) for nite $r$ is brought to the sim ple form

$$
\begin{equation*}
\mathrm{d}_{(\mathrm{r})}(\mathrm{fa} \mathrm{~g})=\mathrm{Y}^{\mathrm{Y}^{\mathrm{r}} \mathrm{y}^{\mathrm{N}}} \underline{\mathrm{~N} \mathrm{da} \mathrm{da}} e^{\mathrm{Nj} \text { ja } \mathrm{J}^{2}}: \tag{26}
\end{equation*}
$$

$$
=1=1
$$

D ue to the factorised structure of this $m$ easure, the transition kemel in (16) acquires the determ inantal form

$$
\begin{equation*}
\operatorname{det} \hat{D}_{f}^{1} ; \forall g(\quad) \tag{27}
\end{equation*}
$$

where the action of the di erential operator ${\hat{D_{f}}}_{f, r g}$ on an arbitrary function $f()$ is de ned as

$$
\begin{equation*}
\hat{D}_{\mathrm{f}} ; \operatorname{rg}^{f}()=\operatorname{det} \hat{I} \quad \hat{v}=\mathrm{d} \quad \mathrm{f}() \tag{28}
\end{equation*}
$$

and its inverse has a convenient integral representation

$$
\begin{equation*}
{\hat{D_{f}}}_{1}^{1} f()=\mathrm{Z}^{\mathrm{Z}} \frac{\mathrm{~d} d}{\mathrm{~d}} \exp ^{\mathrm{n}} \mathrm{j}^{\mathrm{j}} \mathrm{f}(+\hat{v}): \tag{29}
\end{equation*}
$$

In the opposite case of in nite rank, the central lim it theorem ensures that the diagonal matrix elem ents $V$ are independently $G$ aussian distributed. In consequenœ, the di erential operator $\hat{D_{f}} ; \mathrm{g} \operatorname{simpli}$ es to

$$
\begin{equation*}
\hat{D}_{f ; \theta g}=\exp \quad \frac{1}{2} \operatorname{Tr} \hat{\theta}^{2} \frac{d^{2}}{d^{2}}: \tag{30}
\end{equation*}
$$

Here and below when considering the in nite rank case we assum e $\operatorname{TrV}=0$ since a non-zero value of $\operatorname{TrV}$ can be accounted forby a trivialuniform shiff of the spectrum .
3. P aram etric correlation functions
3.1. P aram etric correlation functions in the energy representation

The ob jective of this section is to present a derivation of the multipoint correlation function $R_{n m}$ lequations (38) and (44) below]. The joint distribution function de ned by equations (16) and (27) serves as the basis for this calculation which em ploys a schem e based on the orthogonal polynom ial expansion. In accordance with the de nition (7), the param etric correlation function is represented as

where the source term $S S$ ( $f E g$ ) and $S^{0}\left(f E{ }^{0} g\right.$ ) are de ned as

Integrating over all ${ }^{0}$ we obtain

Let us denote as $n$, and $m$, respectively, the set of all distinct indices a in the $m$ ultiple sum over $1 ;::: ;{ }_{n}$, and the set ofalldistinct indices b in the m ultiple sum over 1;:::; m. It is now convenient to split the product of $\hat{D}^{1}$ 's as

$$
\begin{align*}
& 2 \mathrm{~m}=1 ; z_{\mathrm{m}} \tag{34}
\end{align*}
$$

All the factors in the second product act only on the variables in ( ) while the operators in the rst product act on the variables in both and the source term delta-fiunctions. The Vanderm onde determ inant involves only polynom ials of degree p 1 in its p-th row, so that the action of a product of N identicaldi erentialoperators transform $s$ the elem ents in its p-th row into di erent polynom ials of the sam e degree and $w$ th the sam e leading term. C onsequently,

Integrating by parts over the variables in $m$ we arrive at
$w$ here $\hat{D}_{f}^{y} ; \forall g=\hat{D}_{f} ; \forall g$. The above expression is $m$ anifestly asym $m$ etric $w$ ith respect to the con ning potentialW ( ). As long as all the energies are close to the centre of the band, and the change in the average density of states induced by the potential $V$ is negligible, the action of $\hat{D}$ on $W$ can be ignored. It is instructive, how ever, to consider a m ore general case. To this end, we introduce a new operator

$$
\begin{equation*}
\hat{\mathscr{V}}_{f ;} ; \exp f \quad W \quad()=2 \hat{\mathscr{D}}_{f} ; \forall g \exp \mathrm{fW} \quad()=2 g: \tag{37}
\end{equation*}
$$

$W$ hen (36) is rew ritten in term sof $\hat{\mathscr{B}}$ and $\hat{B}^{y}$, each of the $V$ anderm onde determ inants appears in combination $w$ th ${ }_{N}{ }_{=1} \exp f \quad W \quad()=2 g$, so that they can be equivalently written as det ${ }^{\prime} 1_{1}()$ where' 1()$=\operatorname{expf} W()=2 g p_{1}()$, and $p()$ are the polynom ials orthogonalw ith respect to the weight $\exp f W$ ( )g. Expanding the determ inants, and using the orthonorm ality of the set of functions' ( ), we arrive at the follow ing representation of the correlation function as an ( $n+m$ ) ( $n+m$ ) determ inant:

$$
\begin{align*}
& R_{n m} \quad \underset{0}{f E} g_{a=1}^{n} ; \mathrm{fE}_{b}^{0} g_{b=1}^{m} \tag{38}
\end{align*}
$$

$w$ here the indices $a$ and $a^{0}\left(b\right.$ and $b^{0}$ ) run from 1 to $n$ (from 1 to $m$ ). The kemel

$$
\begin{equation*}
k\left(E ; E^{0}\right)=X_{p=0}^{X^{1}} \prime_{p}(E)_{p}^{\prime}\left(E^{0}\right) \tag{39}
\end{equation*}
$$

describes the correlations am ong the levels of the originalm atrices $H$, while the low er right comer of the $m$ atrix describes the correlation functions $w$ ithin the ensem ble de ned by the distribution function $P(H)=C_{U} \exp f \quad \operatorname{TrW} \quad(H \quad V) g$. The crosscorrelations betw een $H$ and $H^{0}=H+V$ are encoded in the $O$-diagonalblocks of (38). In the bulk scaling lim it the kemel $k$ takes the form [11]
where $!=E^{0} \quad E$ and $=\left(E^{0}+E\right)=2$.
The bulk of the present paper is devoted to the case when the strength of the perturbation $V$ is such that the param etric correlators betw een the \old" and the \new" levels are $O(1)$. This condition is ful lled if $T r V^{2} \quad O\left(\mathbb{N}^{2}{ }^{2}\right)$. In this regim e the operator $\hat{\bar{D}}_{f}$;og can be explicitly evaluated using a representation of $\hat{D}$ as an integral over a vector of $G$ rassm ann variables :

$$
\begin{align*}
& \text { Z } \\
& d d \quad \exp \left[\mathbb{W}^{0}() \quad \hat{v}=2\right] \exp \quad j \hat{j} \quad \hat{v} \frac{d}{d} \\
& =\operatorname{det}\left[1 \quad \hat{\forall W}{ }^{0}()=2 \hat{D}_{\mathrm{f}} \hat{\mathrm{x}}(\hat{\theta}) \mathrm{g}\right. \text {; } \tag{41}
\end{align*}
$$

where $\hat{y}(\hat{\theta})=\hat{\theta}=\left(\begin{array}{l}1 \\ \hat{\theta}\end{array}{ }^{0}()=2\right)$. A ssum ing that all the energies in both sets fE g and $f E{ }^{0} g$ lie within a few level spacings of some central energy, and since the determ inantal structure of (38) ensures that the operators $\hat{D^{\wedge}}$ and $\hat{D}^{1}$ com e in pairs, the determ inant in the prefactor can be dropped.

The derivative of the con ning potential is related to the realpart of the average $G$ reen function via

$$
\begin{equation*}
W^{0}()=2^{Z} \frac{(z)}{z} \quad 2<G(): \tag{42}
\end{equation*}
$$

C onsequently, $r(v)$ can be represented as the solution of the equation

$$
\begin{equation*}
\hat{r}(\hat{\theta})=\hat{\theta}+\hat{\theta}<G() \hat{y}(\hat{v}) ; \tag{43}
\end{equation*}
$$

which can be immediately identi ed as the equation for the reactance $m$ atrix for scattering o the potentialV. In fact, as can be show $n$ using the $m$ ethods ofstatistical eld theory [12], the param etrisation of $\hat{D}$ in term $s$ of the corresponding reactance $m$ atrix retains its validity in the $m$ ore general case of non-invariant distributions $P(H)$. The eigenvalues of the reactance $m$ atrix are conveniently param etrised as tan where are the corresponding phase shifts.

A s discussed above, the param etric correlations generically fall into tw o regim es corresponding to the rank of $V$ being nite or in nite. In the latter case, the condition $T r V^{2} \quad O\left(\mathbb{N}^{2}{ }^{2}\right)$ ensures that, for a generic eigenvalue $v_{i}$ of $\hat{v}$, and at a generic position in the spectrum, $v_{I} W{ }^{\circ}$ ( ) 1. Thus the distinction betw een $\hat{D_{D}}$ and $\hat{D}$ is meaningful only in the nite rank case, and, to sim plify notations, we will use the sym bolf $\hat{D}$ in both cases $w$ ith its param etrisation im plied by the context.

Sim ilarly, to the leading order in the $1=\mathrm{N}$ expansion, the density ofstates () can be approxim ated by an -independent inversem ean levelspacing $1=$, thus sim plifying (38) to the form quoted in [17]:
where $\hat{v}=\hat{v}=$, and $R_{n m}={ }^{n+m} R_{n m}$. In the $r$ ! 1 lim it this equation reproduces the results obtained previously [7, 18]. The representation of $R_{n m}$ in the form of integrals characteristic of the non-linear sigm a m odel calculations 7, 12] corresponds to the Fourier decom position of $\hat{D} k$ and $\left.\hat{D}^{1} \llbracket k \quad\right]$ in 44).

### 3.2. U niversality in shifted distributions

To draw a connection w ith som e previous studies of param etrically deform ed random $m$ atrix ensem bles [22, 23], let us brie y consider the opposite case of a perturbation strong enough to signi cantly a ect the density of states. In this regim $e$, the crosscorrelations are sm all as $1=\mathrm{N}$. There rem ains, how ever, the question of whether the correlation functions of a matrix ensemble de ned by the shifted distribution $P_{V}(H)=C_{U} \exp f \operatorname{TrW}$ ( $H \quad V$ )g are universal. To the best of our know ledge, this question has been so far answ ered in the a mative only in the case when $W$ is quadratic [22] (see also [24] where the case of non-G aussian potential w ith a linear source term was considered). The form alism developed above a ords an opportunity to extend the proof to the case of anbitrary W (H ) (still, how ever, assum ing strong con nem ent). The corresponding correlation functions, as follows from 38), have the determ inantal structure $w$ th the kemel $k_{V}(!;)={\hat{D_{1}}}_{f_{1 ; v g}}^{1 y} \hat{\bar{D}}_{f 2 ; 0 g} k(!;)$. The operator $\hat{D}$ in this regim e is given by equation (30). Expanding the di erence W (2) W (1) ! $W^{0}()$, we obtain
$\mathrm{k}_{\mathrm{V}}(!;)=\operatorname{expf} \quad!W^{0}()=2 \operatorname{gexp} \quad{ }^{2} \mathrm{x}^{2} @_{!} @ \quad \operatorname{expf}!\mathrm{W}^{0}\left(\mathrm{r}=2 \mathrm{~g}=\frac{\operatorname{expfi}!\quad \text { ( )g }}{!}\right.$; (45)
where $x=\operatorname{Tr} \hat{\gamma}^{2}{ }^{1=2}=$. By virtue of (42), the last tw o exponents can be com bined to read $=\exp f!G() g$, where $G(z)$ is de ned as the analytic continuation of the retarded $G$ reen function $G()=d z \quad(z)=(z \quad)+i \quad()$ onto the complex plane $w$ ith cuts along the realaxis outside the support of the density of states ().By em ploying an integral representation of the di erential operator

$$
\exp \quad{ }^{2} x^{2} @_{!} @=\frac{d d}{{ }^{3} x^{2}} \exp ^{n} j^{2}{ }^{2}={ }^{2} x^{2} \quad @_{!}+@^{0} ;(46)
$$

and di erentiating $w$ ith respect to , equation (45) is brought to the form

$$
\begin{aligned}
& \text { @ } \operatorname{expf!W^{0}()=2gk_{v}(!;)]} \\
& =\frac{d d}{{ }_{Z}^{3} x^{2}} \exp \quad j^{2} j={ }^{2} x^{2}=\operatorname{expf}(!\quad) G(+) g G(+4:)
\end{aligned}
$$

A fter a change of variables $r=j \frac{2}{j}, u=e^{i a r g}$ we note that, since $G$ is analytic by construction, the only non-analyticity of the integral over $u$ is due to the pole generated by the solution $u_{0}()$ of the equation ${ }^{2} x^{2} G(+u)+u=0$ (existence of multiple solutions of this equation would contradict level num ber conservation). W e thus nd, upon rescaling $u$ and integrating over $r_{I}$

$$
\begin{align*}
& \text { @ } \left.\operatorname{expf!} \mathrm{W}^{0}()=2 g k_{v}(!;)\right]==d u \frac{\exp f!G(+u) g}{{ }^{2} x^{2} G(+u)+u} G^{0}(+u) \\
& ==\frac{\exp \quad!u_{b}()={ }^{2} x^{2} G^{0}\left(+u_{0}()\right)}{1+{ }^{2} x^{2} G^{0}\left(+u_{0}()\right)} ; \tag{48}
\end{align*}
$$

where the contribution from integrals along the cuts vanishes upon taking the imaginary part of this expression. Integrating over and using $1+{ }^{2} x^{2} G^{0}\left(+w_{0}()\right)\left(d u_{0}=d\right)={ }^{2} x^{2} G^{0}\left(+u_{0}()\right)$, we nd

$$
\begin{equation*}
k_{v}(!;)=\operatorname{expf} \quad!W^{0}()=2+!<u_{0}() g \frac{\sin !v^{\prime}()}{!} ; \tag{49}
\end{equation*}
$$

where the renorm alised density of states is $v()==\psi()={ }^{2} x^{2}$. The exponential prefactors cancel out due to the determ inantal structure of the correlation functions, thus establishing their universal form .
3.3. P aram etric correlation functions in the num ber representation

The \complem entary" number-dependent correlation functions are generically expressed as derivatives of the corresponding generating functions. The archetypal generating function is the probability $P_{n n} 0\left(J ; J^{0}\right)$ to $n d n(J)=n$ levels in the interval $J$ of the unperturbed sequence and $n^{0}$ levels in the interval $J^{0}$ of the perturbed sequence, where $n(J)$ is the num ber of levels in the interval J :
$P_{n n^{0}}\left(J ; J^{0} ; x\right) \quad n ; n(J) n^{0} ; n\left(J^{0}\right)={\frac{(1)^{n+n^{0}}}{n!n^{0}!}}_{k=n k^{0}=n^{0}}^{X^{1}} \frac{(1)^{k+k^{0}} r_{k k^{0}}}{(k)!\left(k^{0} \quad n^{0}\right)!}$ :
$H$ ere $r_{k k^{0}}$ represents the correlation function $R_{k k^{0}}$ integrated over the direct product of
 $J^{0} \mathrm{~m}$ ay, generically, consist of an arbitrary num ber of disjointed segm ents. Equation (50) is a straightforw ard generalisation of the non-param etric analogue $P_{n}$ (J) (see, e. g., A ppendix 7 of $R$ ef. [2]). For later convenience in carrying out the sum $m$ ations, $r_{k k^{0}}$ can be represented in the form of a ferm ionic functional integral

$$
\begin{align*}
& \text { Z Z } \\
& d m_{J}(u) \quad(u) \quad(u) \\
& \text { k Z } \\
& \mathrm{r}_{\mathrm{kk}}{ }^{0}=\operatorname{det} \mathrm{K} \quad \mathrm{D} D \\
& \text { Z Z } \\
& \exp d u \quad d w(u) K \quad{ }^{1}(u ; w) \quad(w) \tag{51}
\end{align*}
$$

where $=\quad$; is a ferm ionic doublet. The $m$ atrix kemel $\hat{\mathrm{K}}$ is easily reconstructed from (38):

$$
K(u ; w)=\quad \begin{array}{cc}
\mathrm{k}(\mathrm{u} ; \mathrm{w}) & \left.\hat{\mathrm{D}}_{\mathrm{w}}^{1} \mathrm{k}(\mathrm{u} ; \mathrm{w}) \quad \mathrm{I}\right]  \tag{52}\\
\hat{\mathrm{D}_{\mathrm{u}}^{\mathrm{y}} \mathrm{k}}(\mathrm{u} ; \mathrm{w}) & \hat{\mathrm{D}}_{\mathrm{w}}^{1} \hat{D}_{\mathrm{u}}^{\mathrm{y}} \mathrm{k}(\mathrm{u} ; \mathrm{w})
\end{array} ;
$$

the $m$ atrix elem ents of the scalar kemel $\hat{k}$ are given by 39), and $I$ is adopted as a shorthand for the D irac -fiunction. For brevity we also drop the subscriptiv ( $\hat{v}$ ), and $\hat{D}$ is understood to be the fiunction of either the single param eter $\operatorname{Tr} \hat{\vartheta}^{2}$ or the r phase shifts param eterising $\hat{r}(\hat{v})$ in the in nite, and nite rank cases, respectively.

Equations (50) (51), and (52) can be used directly to com pute a certain class of correlation functions exem pli ed, e. g., by the correlation betw een level spacings of the original and perturbed level sequences centred at given energies E , and $\mathrm{E}{ }^{0}$, respectively. Since our $m$ ain interest, how ever, is in the correlation functions in the num ber representation, we need to be able to relate the levels ${ }^{0}$ in the new sequence to the param etric \descendant" of a given level in the unperturbed sequence. The absence of level crossings allow s to do this by dem anding, e.g., that if an interval $J=$ ( 1 ; ] of the unperturbed sequence contains exactly $n$ levels (as counted from the bottom of the band), the corresponding interval $J^{0}{ }_{+}$! of the perturbed sequence contains exactly $n+q$ levels, where $q$ is xed and $n$ is arbitrary. By construction, then, the upperm ost level in the interval $\mathrm{J}^{0}{ }_{+}$! is separated by $q \quad 1$ levels from the param etric descendant of the uppem ost level in the interval $J$. Sum $m$ ing over all $n$ we nd the corresponding probability as

$$
\begin{align*}
& =\mathrm{Z}_{0}^{2} \frac{\mathrm{~d}}{2} e^{i q} \underset{\substack{k=0 \\
k^{0}=q}}{\mathrm{X}^{\mathrm{L}}} \frac{(1)^{k+k^{0}+q} r_{k k^{0}}}{k k^{0}!} z_{+}^{k} z^{k^{0}} ; \tag{53}
\end{align*}
$$

where $z=1+e^{i}$. Substituting (51) into (53), one nds

$$
\begin{equation*}
P_{q}\left(J ; J^{0} ; x\right)=(1)^{\mathrm{Z}_{2}} \frac{\mathrm{~d}}{2} e^{\mathrm{iq}} \mathrm{Z}_{\mathrm{q}}(!; \mathrm{x} ;) ; \tag{54}
\end{equation*}
$$

where

$$
\begin{equation*}
Z_{\mathrm{q}}\left(!; \mathrm{x}_{\boldsymbol{\prime}}^{\mathrm{h}}\right)=\operatorname{det} \mathrm{I}_{0} \hat{\mathrm{~K}^{\prime}}()^{\mathrm{i}} \mathbb{X}^{1} \frac{\varrho^{\mathrm{k}^{0}}}{\mathrm{k}^{0}!} \operatorname{det}_{0}^{\mathrm{h}} \mathrm{I}_{0}^{\hat{k}} \quad()^{i} \quad ; \tag{55}
\end{equation*}
$$

and, denoting the $P$ aulim atrioes as i,

$$
()=\begin{array}{cc}
z_{+} & 0 \\
0 & \mathrm{z}
\end{array} ; \quad()=\begin{array}{cc}
z_{+} & 0 \\
0 & \mathrm{z}
\end{array} \quad:
$$

The determ inants are understood as functional determ inants on the space of twocom ponent functions de ned on the product interval $\mathrm{J} \quad \mathrm{J}^{0}$.

A though the form alism in principle can be applied at the spectraledge, we are prim arily interested in the correlation functions in the bulk of the spectrum. Taking the scaling lim it would then greatly facilitate the calculation. In order to avoid unessential com plications related to the energy dependence of the average density of states, we replace $\hat{k}$ w ith its value (40) in the scaling lim it assum ing ${ }^{1}$ ( ) is a constant, and then regularise $k$ as

$$
\begin{equation*}
k \quad(u \quad w)=\frac{\sin (u \quad w)}{(u \quad w)} e^{(1=2) \quad(j u j+j w j)} ; \tag{56}
\end{equation*}
$$

where the lim it ! 0 is implied in all expressions involving this kemel, and the energy variables are rescaled by . U sing equation (51) it is easily shown that $\mathrm{hn}\left(\mathrm{J}_{1}\right) \mathrm{i}=\mathrm{hn}\left(\mathrm{J}_{1}^{0}\right) \mathrm{i}=2=$, and $\left.\mathrm{hn}\left(\mathrm{J}_{1}\right) \mathrm{n}\left(\mathrm{J}_{1}^{0}\right)\right]^{2} \mathrm{i} \quad \mathrm{O}()$. Thus, although the regularisation form ally violates the levelnum ber conservation, the corresponding error tends to zero in the lim it ! 0.At the sam etime, for any nite value of the number of levels in the sem i-in nite intervals $J$ and $J^{0}$ ! is nite, ensuring the convergence of the integrals over energies at the low er lim it. In the follow ing we will suppress the index.

A s w ritten, (54) involves a m atrix oscillating integralkemelde ned on a product of sem i-in nite intervals. H ow ever, as we will now show for the case $q=0$, it can be rew ritten in the form which is (i) m ore am enable to num erical analysis, and (ii) $m$ akes the integrability of the kemel (in the sense discussed in Ref. [25]) manifest. W thout loss of generality, we can set $=0$, and shift the variables so as to de ne the determ inant on the quadrant ( 1 ;0] ( $1 ; 0]$. The corresponding shift operator is absorbed into the rede nition $\hat{D}!e^{!d=d u} \hat{D}$. The term involving the -function in the upper right comer of (52) can be separated to reveal the dyadic structure of the rem ainder:

$$
\hat{\mathrm{K}}=\begin{array}{ccccc}
\mathrm{I} & \hat{\mathrm{D}} & \hat{D^{1}} & \hat{\mathrm{~B}}^{1} & 0 \\
0 & \hat{D}^{1} I
\end{array}
$$

where the we have also used $\hat{D_{W}^{y}} k(u \quad w)=\hat{D_{u}} k(u \quad w)$. Now, using the identities $\left(I_{0}+z \hat{D^{1}} I_{+}\right)^{1}=\left(I_{0} \quad z \hat{D}{ }^{1} I+\right)$, and $\operatorname{det}\left(I_{0}+z \hat{D}{ }^{1} I_{+}\right)=1$, where $+=\left(\begin{array}{c}1 \\ \mathrm{~h}\end{array} \mathrm{i}_{2}\right)=2$, one obtains
$\operatorname{det} I_{0} \hat{K}()^{1}=\operatorname{det} I \quad z_{+} \hat{k} \quad z z \hat{k} \hat{D}{ }^{1} I \hat{D}+z \hat{D^{1}}{ }^{1} \hat{k} \hat{D}{ }^{1}:(57)$

Em ploying the Fourier representations,

$$
\underset{(u)}{k(u)}=\frac{1}{2}_{1}^{Z_{1}^{1}} d \quad(1 \quad) \quad(1+) \quad e^{i} \quad u ;
$$

one nds

$$
\begin{aligned}
& { }^{h} z_{+} \hat{k} \quad z z \hat{k} \hat{D^{\prime}}{ }^{1} I \hat{D^{\prime}}+z \quad \hat{D}^{1} \hat{k} \hat{D^{\prime}} \quad(u ; w)
\end{aligned}
$$

where in the in nite rank case

$$
\begin{equation*}
D()=\exp i!+{ }^{2} x^{2}{ }^{2}=2 \text {; } \tag{59}
\end{equation*}
$$

and in the nite rank case

$$
D()=\operatorname{expfi}!g_{=1}^{Y^{r}}\left[1 \quad i \tan _{k}\right]:
$$

$F$ inally, the cyclic invariance of the determ inant and the identity $z_{+}+z=z_{+} z$ are used to perform the integrals in the $u-w$ space, $\underset{i}{ }$ ringing the determ inant to the form

$$
Z_{0}(!; x ;) \quad \operatorname{det} I 0 \hat{K}()=\operatorname{det}_{[1 ; 1]}\left[\begin{array}{ll} 
& K()] ; \tag{61}
\end{array}\right.
$$

$w$ here the $m$ atrix elem ents of the kemelK ( ) are

$$
\begin{equation*}
\mathrm{K}(; ;)=\frac{1}{4 i}_{\mathrm{P}}^{\mathrm{D}(\mathrm{D}(\mathrm{D}(\mathrm{~F}(;) \mathrm{F}(;)} \text {; } \tag{62}
\end{equation*}
$$

and

Here the integral is understood in the sense of the Cauchy principal value, $w$ th variables and restricted to the interval [ 1;1]. W e employ the notation $x$ to denote the param etric dependence of $Z$ in both nite and in nite rank cases. A sim ilar, although som ewhat $m$ ore cum gersom $e$, expression, is easily reconstructed for the contribution of det I $\hat{K} \quad()$ in the $q \in 0$ case.

Equations (61), (62), and (63) form the central results of this section. In the rem ainderwe will consider several applications of these equations to the calculation of Rum ber-dependent correlation functions. T he integral of the generating function itself
$\mathrm{d} Z_{0}\left(!; x_{;}\right)=2$ gives the probability $\mathrm{P}_{0}(!; x) \quad P_{0}(J ; J+!)$. In order to obtain the correlation functions $P_{q}$ and $C_{q}$ introduced above, we rew rite their de nitions in the form

$$
\begin{align*}
& P_{q}(!; x)=\begin{array}{c}
D \\
D
\end{array} \mathrm{n}(J) @ n J_{+!}^{0} \quad n(J) ; n\left(J^{0}+!\right)+q_{E} ;  \tag{64}\\
& C_{q}(x)=@_{x} n(J) @_{x} n J^{0}+1 \quad n(J) ; n\left(J^{0}+!\right)+q: \tag{65}
\end{align*}
$$

U sing translational invariance both in the energy and the param eter spaces, rescaling the energies by, and rescaling the variables in $x$ by $C_{0}{ }^{1=2}$ [7], we obtain for the rescaled correlation functions $p_{q}$ and $c_{q}$ [26]

$$
\begin{align*}
& \mathrm{P}_{\mathrm{q}}(!; \mathrm{x})=(1)^{\mathrm{q}} \mathrm{Z}_{2}^{0} \frac{\mathrm{~d}}{2} \frac{\mathrm{e}^{\mathrm{iq}}}{\mathrm{Z}_{+} \mathrm{z}} \quad \mathrm{Z}_{2}^{2} \mathrm{Z}_{\mathrm{q}}(!; \mathrm{x} ;) ;  \tag{66}\\
& C_{q}(x)=(1)^{q} \int_{1}^{1} d!\sum_{0}^{2} \frac{d}{z_{+} z}(Q)^{2 q} Z_{q}(!; x ;): \tag{67}
\end{align*}
$$

Let us now consider several special cases. (i) In the in nite rank case x reduces to a single param eter $x=\operatorname{Tr} \hat{v}^{2}=2$. The single leveluniversalvelocity autocorrelation function $C(x) \quad \subset(x)$ is plotted in Fig. 1. For com parison we also show the results of direct num erical sim ulation of large random $m$ atrices [27]. W e also nd, based on num erical evaluation of equations (66), (61), (62), and (63) that the function $\mathrm{p}(!; \mathrm{x}) \quad \mathrm{p}(!; \mathrm{x})$ \{ the distributiop of param etric single level shifts $\{$ has a G aussian form $p(!; x)=\exp \quad!^{2}=2 \quad(x)=\overline{2(x)}$, in accordance $w$ ith the earlier conjecture [20]. An analytical proof of this statem ent, as well as nding an analytical expression for the width (x) (shown in the inset in $F$ ig. 11) are som e of the open questions posed by the results of the present investigation.

Figure 1. Single level universalvelocity autocorrelation function obtained from 67, 61, 62, and 63 (solid line) vs. direct num erical sim ulation of large random $m$ atrices [27] (dots). The width (x) of the Gaussian distribution of level shifts together w ith the $x^{2}$ asym ptotics at $s m$ all $x$ is show $n$ in the inset.
(ii) In the nite rank case further progress can be m ade due to a sim ple pole structure of $D^{1}$ ( ). Leaving a detailed consideration of the nite rank case to a future publication, we present here the results for $c_{0}$ and $p_{0}$ in the $r=1$ case. $x$ is now param etrised by a single phase shift. In Ref. [17] the distribution $p_{0}$ for $r=1$ was found using the fact that, as a special property of $r=1$, this distribution coincides $w$ th the level spacing of the com bined ensem ble of levels $f \quad g\left[f{ }^{0} g\right.$. U sing the present form alism, this quantity, as well as the corresponding $c_{0}$ can be evaluated in a m ore direct way. Introducing an auxiliary non-param etric kemel

$$
\begin{equation*}
k(;)=\frac{1}{2} i \frac{1}{} \quad \operatorname{expfi}!(\quad) 9 \tag{68}
\end{equation*}
$$

its $G$ reen function $g(;)=\left(\begin{array}{ll}I & k\end{array}{ }^{1}\right.$, and the determ inant $d(!)=\operatorname{det}\left(\begin{array}{ll}\left(\begin{array}{l}\text { k }\end{array}\right) \text {, we }\end{array}\right.$ nd (assum ing $>0$ )
$c_{0}^{(r=1)}()=\frac{d^{2}}{d^{2}} \int_{0}^{Z_{1}} \frac{d!}{2} d(!) \exp f \quad!\arctan \quad g_{1}^{Z_{1}} d d \frac{g(;) \exp f i!g}{\arctan }$ i

A som ew hat $m$ ore lengthy expression is obtained for $p_{0}$ :

$$
\begin{align*}
& \mathrm{p}_{0}^{(\mathrm{r}=1)}(!;)=(!) \frac{d(!)}{2} \exp f \quad!\arctan g \mathrm{Z}_{1} d \mathrm{~d} \frac{\mathrm{~g}(;) \operatorname{expfi}!\mathrm{g}}{1 \mathrm{i} \tan } \\
& \frac{(1 \quad i \tan \}}{\tan }+(1 \quad i \tan ) t(!) \quad \mathrm{T}(!;) ; \tag{70}
\end{align*}
$$

where $t(!)={ }_{R_{1}} d \operatorname{dg}(;) \exp f i \quad!(\quad)$, and $\mathrm{Z}_{1}$ $\mathrm{T}(!;)=\mathrm{d}_{1} \mathrm{dg}(;) \operatorname{expfi}!(\quad) \mathrm{g}(1 \quad$ i $\tan )$ :
Up to a simple transform ation, the kemel $k$ is identical to the kemelwhich controls the non-param etric level spacing distribution $\mathrm{S}_{1}$. In light of the \interleaved com bs" constraint on the evolution of levels when $r=1$, such a connection to $S_{1}$ is not unexpected.

W thin the fram ew ork presented here various num ber-dependent correlation functions in the unitary ensem bles can be com puted \at w ill". N evertheless, several open questions rem ain unanswered, and their resolution would greatly enhance our understanding ofparam etric evolution of random $m$ atrices. A s already $m$ entioned, the G aussian form of $p_{0}$ in the $r$ ! 1 case is probably an indicator that the integration can be perform ed analytically in some form in the in nite rank case as well. If so, a more \processed" expression for $c_{0}^{r!}{ }^{1} \mathrm{~m}$ ay em erge, throw ing $m$ ore light on the properties of the kemelK ( ). Separately, an analysis of the asym ptotic behaviour of the generating functions along the lines of $R$ ef. [28] is a natural way to develop the present form alism fiurther. Finally, the technique of \counting" the num ber of levels betw een the spectral edge and a point in the bulk of the spectrum by means of introducing a regularised kemel should be applicable to ensembles w th di erent sym $m$ etries, so that if an analogue of (38) is obtained for such ensem bles, it is likely to open the door to the com putation of the corresponding num ber-dependent correlation functions.
