W e report an exact solution for the noise spectrum of spincurrent without charge-current in a spin eld e ect transistor (SFET). For the SFET with two leads, it is found that both auto- and cross-correlation functions are needed to characterize the noise of spin-current. A shot noise is also generated for the charge-current even though the net chargecurrent is identically zero. The noise spectra of spin-current and charge-current depends on the coupling strength between the SFET and the leads, and they m ay behave qualitatively di erently. W e also present results of noise spectra in the adiabatic regim e.

73.23 Ad,73.40 Gk,72.10 Bg

D ue to the particle nature of carriers, the uctuation of charge-current gives rise to the notion of shot noise¹. For a norm alsystem, the current correlation between different probes (cross correlation) is negative for Ferm ions and positive for Bosons^{2;4}. The correlation can be more complicated if superconducting leads are present⁶ {¹². Im portantly, the correlation properties provide further inform ation, in addition to those contained in conductance or charge-current, for m esoscopic conductors². So far all theoretical and experimental attention have been devoted to correlations of charge-current.

In this paper, we theoretically investigate the correlation of spin-current in the absence of charge-current in a two-probe device. Indeed, to be able to generate and control spin-current is of great in portance for spintronics¹³, but the noise spectra of spin-current has never been studied before. A pure spin-current can behave qualitatively di erently from charge-current because spins can ip so that spin-current m ay not be conserved. Therefore the cross correlation of currents m ay not be directly related to the auto-correlation. On the other hand, the conservation of charge forces the cross correlation and autocorrelation of charge-current noise spectra to di er by just a minus sign in a two-probe system. This dierence necessarily indicates that the noise spectra of spincurrent is more complicated. To be more speci c, we will investigate the spin-current correlation in a twoprobequantum spin elde ect transistor (SFET)¹⁴. The detailed working principle of the SFET is summarized elsewhere¹⁴ and we refer interested readers there: this device delivers an instantaneous spin-current but without generating a net charge-current by the help of a rotating magnetic eld. Roughly, if all the spin-up electrons in a conductor move to one direction while an

equal number of spin-down electrons move to the opposite direction, the net charge-current vanishes because $I_e = e\left(I_* + I_{\sharp}\right) = 0$; and a nite spin-current results because $I_s = h{=}2\left(I_* \quad I_{\sharp}\right) \notin 0$. Here $\left(I_*; I_{\sharp}\right)$ are the electron current for spin-up and spin-down electrons respectively. The SFET provides a mechanism for this e ect, and there are a number of other possibilities to produce $I_s \notin 0$ with $I_e = 0$ which is the subject of several recently studies both theoretically $^{15}\{^{17}$ and experimentally 18 .

For a two-lead device, correlations can be formed by quantities measured at the same lead the autocorrelation, or by quantities measured at the two different leads the cross-correlation. As discussed above, due to a lack of spin-current conservation, we need both auto-and cross-correlation to characterize the noise spectra of spin-current. It has been well know n¹⁹ that antibunching in a Fermionic system gives rise to negative de nite cross-correlation for charge-current, and much of the recent research has been devoted to situations where the sign of this correlation¹ can be reversed. For spincurrent, the situation is very dierent. We found that when the coupling between SFET and lead is strong, the cross-correlation function of spin-current is positive definite. In the interm ediate or weak coupling regime, the cross-correlation of spin-current is positive when the system is far o a quantum resonance but it becom es negative near the resonance. In the adiabatic regime, the shot noise of a SFET involving only a single lead vanishes at resonance which corresponds to the quantization of delivered spin. As the coupling strength between the single lead and the SFET is varied, the shot noise is found to displays di erent num ber of peaks depending on the coupling strength. M any of these features persist in the nonadiabatic regime. Finally, an oscillation between positive and negative shot noise is observed as a SFET parameter is tuned. These ndings are qualitatively di erent and much richer than the behavior of charge-current correlations.

We start by considering the SFET which generates spin-current without charge-current, described by the following H am iltonian 14

$$H = \begin{array}{c} X & X \\ _{k}C_{k}^{Y} C_{k} + [+ B_{0}\cos]d^{Y}d \\ _{k}; ; = L;R & X \\ + [exp(i!t)d_{n}^{Y}d_{\#} + hc:] + [T_{k} C_{k}^{Y} d + hc:] (1) \\ _{k}; ; = L;R \end{array}$$

where the rst term stands for the non-interacting electrons in lead = L;R and C $_{k}^{y}$ is the creation oper-

ator. Note that we have set the same chem ical potential for the leads L and R because we are only interested in the quantum pumping e ect²⁰ of the SFET. The second term describes the scattering region of the SFET which is a quantum dot characterized by an energy level and spin . A gate voltage $v_{\rm q}$ is applied to control the energy level. The SFET generates spin $current^{14}$ via a time-dependent magnetic eld B (t) = B_0 [sin cos!ti+ sin sin!tj+ cos k]. The last term of the H am iltonian denotes tunneling between the leads and the dot with tunneling matrix elements $T_{k} = L_{R}$. Im portantly, we apply a rotating magnetic eld (the term proportional to) rather than an oscillating eld: a counterclockwise rotating eld allows a spin-down electron to absorb a photon and ip to spin-up, and it does not allow a spin-up electron to emit a photon and ip to spin-down. As schematically shown in the upper inset of Fig.(2), it is this symmetry breaking eld that provides the driving force to deliver a pure DC spin-current to the leads^{21} .

To analyze the noise spectrum of spin-current, we dene a spin-dependent particle current operator (h = 1)

$$\hat{J}; \qquad \begin{array}{c} X \\ k \end{array} = \begin{array}{c} \frac{d[C_k^y C_k]}{dt} = \begin{array}{c} X \\ i \end{array} \begin{bmatrix} T_k C_k^y d & hx:]: \end{array}$$
(2)

Then the charge-current operator is $\hat{\Gamma}_q = q^{L} \quad \hat{J}$; An important quantity for our study is the correlation between spin-dependent particle currents in lead and ,

$$S \stackrel{\circ}{=} < [\hat{J} (t_1) J][\hat{J} \circ (t_2) J \circ] > (3)$$

with J $\langle \hat{J} \rangle$ and ; ⁰ denoting spin indices. Here $\langle \rangle$ denotes both statistical average and quantum average on the nonequilibrium state. The noise spectra of both charge-current and spin-current can be obtained from the correlation S ⁰.

W e calculate S $^{\circ}$ using standard K eldysh nonequilibrium G reen's function (NEGF) form alism ¹⁴. Brie y, we substitute Eq.(2) into Eq.(3), de ne NEGF G [<] and G [>] with properly contour ordered operators, and apply the theorem of analytic continuation¹¹ so that the contour G reen's functions are extended to the realtim e axis. This standard and widely used NEGF technique allows us to obtain the exact expression for the zero-frequency spindependent correlation²².

We now exam ine noise spectrum in the low temperature lim it kT << h!, i.e. the shot noise. First, setting = L, = R in S , we investigate shot noise of the charge-current (cross correlation). It has been shown in Ref. 14 that the net charge-current of the SFET is identically zero^{21} , how ever here we nd that shot noise of it is nonzero. The shot noise of the charge-current is

$$S_{ele} = \langle I_{L} | I_{R} \rangle = q^{2} \sum_{a}^{N} S_{LR}^{a}$$
$$= q^{2} \sum_{a}^{R} \frac{dE}{2} [jG_{\#}^{r} f + jG_{\#}^{r} f]f_{\#} (1 f_{\#})$$
(4)

where $G^r = = [(E + i = 2)(E + ! + i = 2)^2]$ is obtained from Ref.14. Here is the linewidth function, $f_{"} = f_{"}(E)$, and $f_{\#} = f_{\#}(E !)$. We conclude that $S_{ele} \notin 0$ although the instantaneous charge-current is zero¹⁴. The excess noise has the following lineshape in the adiabatic limit (i.e. ! ! 0),

$$S_{ele} = -\frac{q^2!}{2} \frac{2_{L} R^2}{(2+2)^2+(2+2)^2+(2+2)^2}$$
(5)

here is the resonant level of the quantum dot and we have set = =2 and $E_F = 0$. As expected, the excess noise (cross correlation) in charge-current is always negative. A single peak is found at = 0 for =2 while a double peak structure occurs when > =2. This can be understood as follows. When the spin ip magnetic eld is turned on, the spin degeneracy of resonant state is broken. Two resonant states are found at

i =2 with level spacing 2 and half width =2. W hen > =2, the two resonant states do not overlap and we obtain two peaks. However, if =2, only one peak is showed up due to the overlapping of resonant states. Finally, the auto-correlation is obtained by setting = = L in S⁰, and it is straightforward to show < I_L I_L >= < I_L I_R >. This is the expected result for charge-current which is a conserved quantity, i.e. $I_L + I_R = 0$.

Next, we calculate the shot noise for spin-current. The cross correlation spin-current shot noise is found to be:

$$S_{\text{spin};1} = \langle (J_{L}, J_{L}, J_{L}, J_{R}, J_$$

and the auto-correlation is found to be:

$$\begin{split} S_{\rm spin;2} &= \langle (J_{\rm L}, J_{\rm L}$$

In contrast to the shot noise of charge-current, we need both the cross- and the auto-correlation to characterize the shot noise for spin-current for the two-lead SFET. The reason is because a spin-current is not conserved due to the spin ip mechanism introduced by the rotating magnetic eld. In the adiabatic limit, the cross correlation reduces to

$$S_{spin;1} = \frac{!}{4} \frac{ \lfloor R \\ (2 + 2) = 4 \\ (2 + 2) = 4 \\ (2 + 2) = 4 \\ (2 + 2) = 4 \\ (2 + 2) = 4 \\ (2 + 2) = 4 \\ (2 + 2) = 4 \\ (2 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4 \\ (3 + 2) = 4$$

Hence, cross correlation S_{spin;1} can be either positive or negative depending on a number of parameters: the

gate voltage which controls the energy level position, the linewidth function , and the external magnetic eld (see Fig.1). Far away from resonance, the strength cross correlation is always positive when x >2 (with $j \neq j$) regardless of the coupling strength between х quantum dot and the leads. On the other hand, for x < 2, the cross correlation is positive de nite when the coupling of the lead to the quantum dot is strong such that > 2(1 + 2 x). When the coupling to the lead is in the intermediate range $2j \overline{2} \times 1j < <$ $2(1+\frac{1}{2}x)$, the cross correlation turns to negative. In the weakly coupled regime $< 2j^{2} \overline{2} x 1j$, the cross correlation becom espositive again. The cross correlation is zerowhen = $2(\frac{r}{2} \times + 1)$ or = $2j^{r} \times 2 \times 1j$ with x 2. Interestingly, as one varys the ratio =(2), di erent lineshapes are found for the cross correlation: (1) in the strong coupling regime (compared with 2): $=2 > (2 + \frac{1}{3})$, the cross correlation is positive defin ite with a broad peak at = 0 (see inset of Fig.1); (2) As one decreases the coupling strength such that $< =2 < (2 + \frac{12}{3})$, the positive peak at = 0 becom es a localm in im um and a double peak structure appears. This can also be seen in the shot noise for the charge-current (auto correlation)²³. Due to the overlap of the two resonant states, two peaks are found (solid line in Fig.1); (3) As one further decreases , a third peak em erges at = 0 when > =2 > (2) 3) (so that two resonant states do not overlap) (see dotted line in Fig.1); (4) nally, in the weak coupling regime (=2 < (2 3)), the third peak splits and a fourpeak structure appears in the shot noise (dashed line in Fig.1). Because of the spin ip mechanism, both spinup and spin-down electrons are contributing to the spin current. The cross correlation between spin up electrons (or spin down) is negative de nite while the cross correlation between spin-up electron and spin-down electron is positive de nite. The competition between these two contributions gives rise to either a positive or a negative cross correlation. Such a com plicated behavior is qualitatively di erent from the correlation in charge-current.

In the adiabatic regime, the auto-correlation is obtained from Eq.(7),

$$S_{spin;2} = \frac{! {}_{L} {}^{2} [({}_{L} + {}_{}) ({}^{2} + {}^{2} = 4 {}^{2})^{2} + {}_{R} {}^{2} {}^{2}]}{4 [({}^{2} + {}^{2} = 4 {}^{2})^{2} + {}^{2} {}^{2} {}^{2}]}$$
(9)

which is positive de nite. W hen the cross correlation is zero, the auto correlation is ! $_{\rm L}\,{=}\,(8\,$).

The SFET can operate with a single lead¹⁴. In this case, the shot noise is found to be

$$S_{spin} = \frac{! 2^{2} (2 + 2 = 4 2)^{2}}{2 [(2 + 2 = 4 2)^{2} + 2 = 2 2]^{2}}$$
(10)

We observe that this shot noise is positive de nite and it displays a single to four-peak structure in the lineshape as is changed. This is similar to the behavior of S_{spin} ; $\frac{1}{2}$. When > =2, the shot noise is zero at $= \frac{1}{2} \frac{2}{2} = 4$. For a single lead SFET, the spin current was found before¹⁴,

$$I_{s} = \frac{!}{2} \frac{2}{(2 + 2)^{2} + 2}$$
(11)

W hen the shot noise is identically zero, $I_{\rm s}$ = $\,!=(2)$. This means that the SFET pumps out two spin quanta (h = 1) in a period = 2 =!. This gives an exam – ple of \optim al" spin pump. The analogous optim al charge pum p^{24} was discussed in literature which is actually rather di cult to achieve $^{25;26}$.

Our exact solutions Eqs.(6) and (7) also allow the investigation of shot noise of spin-current in the nonadiabatic regime (! \neq 0). We x eld strength = 0:02 in the following calculation. W hen frequency ! 6 0, the noise becom es asym m etric with respect to the gate voltage. For = 0.017, the in uence of frequency is shown in the left inset of Fig 2. We observe that when ! = 0.01(solid line), the depths of the two minim a decrease. As frequency changes to ! = 0.02 (dotted line), the noise is still negative for a wide range of gate voltages and is positive for some negative gate voltages. Finally, when ! = 0:03, the noise becom es positive de nite. The noise as a function of frequency is depicted in Fig 2. The oscillatory behavior between positive and negative noise of the spin-current is observed, which is due to photon assisted process.

In sum mary, we have, for the rst time, presented an exact solution of the shot noise for spin-current generated by the SFET which is essentially a quantum spin pump at arbitrary pum ping frequency. For the device discussed here, the instantaneous charge current is zero but its shot noise is nite. Due to the spin ip mechanism in the SFET, the spin-current is not conserved. As a result, both auto-correlation and cross correlation must be used to characterize the shot noise of spin-current for our twolead system . A way from a quantum resonance, we found that the cross correlation becomes positive due to the occurance of carriers with di erent spin. In the adiabatic regime, the auto-correlation of a quantum dot connected to a single lead is calculated and found to be zero when the pum ped spin is quantized. As the coupling strength between the single lead and the quantum dot is varied, we found that the shot noise displays di erent lineshapes in the di erent coupling regimes.

- ²¹ Brie y, the SFET works as follows. The z-component of eld B (t) splits the level into # < ". The chemical potential of the leads is adjusted so that # < < " as shown in the upper inset of Fig.(2). A spin-down electron can tunnel into # from the left lead, it absorbs a photon due to the rotating eld and ip its spin to occupy ". Because " > , the now spin-up electron tunnels out to the leads easily. The same process occurs to spin-down electrons com ing from the right lead. Therefore, spin-down electrons ow toward the quantum dot while spin-up electrons electrons ow away from the dot, giving rise to a zero net charge-current and a nite spin-current. See R ef. 14 for m ore details.
