
#### Abstract

Thom as Volz, Stephan D urr, Sebastian Emst, A ndreas M arte, and G erhard Rem pe M ax-P lanck-Institut fur Q uantenoptik, $H$ ans $-K$ opferm ann-Str. 1, 85748 G arching, $G$ erm any (D ated: A pril 14, 2024)  is m easured in the vicinity of a Feshbach resonance near 1007 G . Experim entally, the scattering length is determ ined from the m ean- eld driven expansion of a B ose E instein condensate in a ho$m$ ogeneousm agnetic eld. The scattering length is $m$ easured as a function of the $m$ agnetic eld and agrees w ith the theoretical expectation. The width of the resonance is determ ined to be 0.20 (3) G , the position of the zero crossing of the scattering length is found at 1007.60 (3) G .

PACS num bers: $34.50 .-s, 03.75 \mathrm{Nt}, 32.80 \mathrm{P} \mathrm{j}$

A Feshbach resonance o ens a possibility for tuning the interactions in ultracold atom ic gases sim ply by applying a m agnetic eld. Feshbach resonances have been used to induce a controlled collapse of a Bose E instein condensate ( BEC ) [ [1] $\left.]_{1}^{1}\right]$, to create a coherent supenposition of an atom ic BEC and a m olecular state $\bar{R}, r, 1$ a bright soliton in a BEC [EL', 'T1T'], and to create a BEC of $C$ s atom $s$ [ $\left[\frac{6}{6}\right]$. Various groups are currently trying to use a Feshbach resonance to create a super uid phase in a degenerate Ferm i gas. F irst results tow ards this goal have recently been published [ $\left.\overline{7}_{1} 1\right]$.

Feshbach resonances have been observed in gases of
 $W$ th the isotope studied in this paper, ${ }^{87} \mathrm{R} b$, tw o technical problem smust be tackled. O ne problem is that in ${ }^{87}$ Rb Feshbach resonances exist only for intemal states that cannot be held in $m$ agnetic traps (except for som $e$ sp in m ixtures). A nother, $m$ ore severe problem is that the Feshbach resonances in ${ }^{87} \mathrm{Rb}$ are unusually narrow : T he broadest resonance located near 1007 G is predicted to be only 0.17 G wide. T his im poses severe constraints on the current sources used to create the magnetic eld. Yet, ${ }^{87} \mathrm{Rb}$ is the isotope used in the vast m a jority of today's BEC experim ents, thus stim ulating a strong interest in investigating the possibility of $m$ anipulating the atom ic interaction in this isotope. In a recent experim ent, we were able to precisely locate m ore than 40 Feshbach resonances in ${ }^{87} \mathrm{Rb}$ by observing enhanced atom loss [1] [1]. Sim ilar results for the broadest resonance were obtained very recently at the U niversity of 0 xford $\left.[1] \bar{T}_{1}\right]$.

In the ultracold regim $e$, the elastic scattering properties are fully characterized by the s-w ave scattering length $a$. $Q$ uantitative $m$ easurem ents of a near Feshbach resonances have previously been reported for 3 isotopes:
 im ents are based on a $m$ easurem ent of either the $m$ eaneld energy of a BEC or the them alization rate in a non-degenerate gas.

In this paper, the m ean-eld energy of a BEC is used to m easure a in ${ }^{87} \mathrm{Rb}$ in the vicinity of the Feshbach resonance near 1007 G. O ur m ethod di ers slightly from
 value of the $m$ agnetic eld was applied while the atom $s$ were still trapped and the atom shad tim e to equilibrate
before being released from the trap. In this paper, how ever, we rst tum o the trap and then Sw itch to the nal value of the $m$ agnetic eld. This im proves the signal-tonoise ratio as discussed at the end of this paper.

The experim ental set-up is only brie y sum $m$ arized here. M ore details are given in Ref. [16]. A doubleMOT system is used for cooling and trapping of atom ic ${ }^{87} \mathrm{Rb}$. T he atom s are then optically pum ped to the state fifm $\mathrm{m}_{\mathrm{f}} \mathrm{i}=\mathrm{l}$; 1 i and loaded into a Io eP ritchard m agnetic trap, in which a radio-frequency (rf) eld drives evaporative cooling to the BEC phase transition. It tumed out that BECs w th the sam e properties as in $R$ ef. [ $[1]$ d can be created $w$ th a m uch faster rf sw eep than described there. The optim ized rf sw eep lasts only 5.1 s , resulting in an overall cycle tim e of 15 s .

A fter creation of the BEC, the atom s are transferred into an optical dipole trap and held there for roughly 0.5 s . The optical trap is $m$ ade of two beam $s$ from a Nd :YAG laser ( $=1064 \mathrm{~nm}$ ), w ith the beam s crossing at right angles. O ne beam propagates horizontally, along the symm etry axis of the $m$ agnetic trap. The second beam subtends an angle of 25 w ith the horizontalplane. $T$ he beam $w$ aist ( $1=e^{2}$-radius of intensity) and pow er are 33 m and 38 mW for the horizontal beam ; and 77 m and 115 mW for the second beam. D ue to the tighter w aist, the horizontalbeam creates a stronger con nem ent than the second beam .

The horizontalbeam creates an estim ated trap depth in the horizontal plane of $\mathrm{k}_{\mathrm{B}} \quad 3 \mathrm{~K}$. In the verticaldirection, the trap barely supports the atom $s$ against gravity w ith a trap depth of $k_{B}$ 0:8 K . The horizontal beam creates negligible con nem ent along its propagation direction. The second beam solves this problem w ithout changing the con nem ent in the other two directions signi cantly. T he polarizations of the tw o light beam sare orthogonal, so that no optical lattioe is form ed.

In a coordinate system, where the z axis is the sym $m$ etry axis of the $m$ agnetic trap and where gravity points along $x$, the trap frequencies are $\left(!_{x} ;!_{y} ;!_{z}\right)=2$ (120, $170,50) \mathrm{Hz}$. The rst two frequencies di er due to the gravitational sag. Typically, the atom num bers in the BEC and in the them alfraction are $10^{5}$ each. The peak density in the BEC is $210^{14} \mathrm{~cm}^{3}$. The optical trap is not designed to $m$ axim ize the atom number in
the BEC. Instead, we try to avoid high peak densities in order to reduce density-dependent losses.
$D$ uring the transfer from the $m$ agnetic trap to the opticaltrap, a $s m$ allm agnetic bias eld (B 1 G ) preserves the spin polarization of the atom $s$. A fter the transfer to the dipole trap, a strong hom ogeneous $m$ agnetic eld (B 1000 G ) is applied in the opposite direction. T he rapid sw itching-on of this eld (at rates up to $700 \mathrm{G} / \mathrm{m} \mathrm{s}$ ) ips the atom ic spins from state 11 ; $1 i$ to the absolute ground state $1 ; 1 i$, in which the Feshbach resonance occurs. W ith thism ethod, the spin- ip e ciency is so close to $100 \%$, that a Stem $-G$ erlach $m$ ethod does not show any signi cant signal from atom $s$ in w rong spin states. We estim ate the detection $\lim$ it of this $m$ easurem ent to be 2 \%.
The 1000-G eld is typically not set exactly onto the Feshbach resonance right aw ay. Instead, the eld is held a few G above orbelow the Feshbach resonance for typically 500 ms . D uring this tim e, therm aldrifts due to the

12 kW heat load dissipated in the coils have som e tim e to settle. N ext, the optical trap is sw itched o and sim ultaneously $B$ is jum ped to a value very close to or right at the Feshbach resonance. A fter holding $B$ at its nal value for $6 \mathrm{~ms}, B$ is sw itched o com pletely. The jum $p$ to the nal eld value actually takes $0: 5 \mathrm{~m} \mathrm{~s}$, the com plete tum-o $2 \mathrm{ms}$. . After an expansion tim e of the order of 20 m s , an absorption m age of the expanded cloud is taken w th a CCD cam era. T he atom num ber and size of the BEC and of the surrounding them alcloud are determ ined from a two-dim ensional to the CCD picture. $T$ hem agnetic eld was calibrated using $m$ icrow ave spectroscopy in the vicinity of the Feshbach resonance w ith an accuracy of 0.03 G .

F igure ${ }_{1}^{-1} 1 \mathrm{l}$ show s the size and atom num ber of the expanded BEC measured with the tim ing sequence described above. A s expected, the size increases (decreases) as the Feshbach resonance is approached from below (above). A dditionally, the atom num ber is reduced as one approaches the resonance from either side. N o BEC is left betw een 1007.37 G and $1007.53 \mathrm{G} . \mathrm{T}$ he separation of ad jacent data points in F ig. equals the estim ated $m$ agnetic eld resolution due to the $m$ easured current noise.

A s one gets very close to the Feshbach resonance from either side, the upw ard (dow nw ard) trend in the width is reversed. On the low - eld side of the resonance, this is a trivial consequence of the decrease in atom num ber, because a low er-density B EC releases lessm ean- eld energy that drives the expansion. O $n$ the high- eld side of the resonance, how ever, the e ect is related to the instability of the BEC in a regim e of negative a discussed later in this paper.

In order to extract a from the $m$ easured size of the expanded BEC, the expansion processm ust_be m odelled. To this end, the m odel presented in Ref. $\left[\underline{1} 11_{1}^{1}\right]$ is extended to include a possible tim e dependence of a during the expansion. W e start.by rst ignoring the observed change in atom number. This e ect $w$ ill be inconporated in the

FIG.1: Vertical half width ( ) and atom number ( ) of the expanded BEC as a function ofm agnetic eld B. D ata points in the left (right) half of the gure were obtained by jum ping tow ards the Feshbach resonance from sm aller (larger) B, and for an expansion tim e of $18 \mathrm{~ms}(23 \mathrm{~ms})$. B was jum ped to its nalvalue at the $m$ om ent of release of the atom $s$ from the trap. B w as held there for 6 m s and then sw itched 0 . The vertical line at 1007.60 G indicates the onset of instability of the BEC due to negative values of a.
analysis later on.
In itially, the BEC is con ned in a harm onic potential $w$ th trap frequencies $\left(!_{x} ;!_{y} ;!_{z}\right)$. In the $T$ hom asFerm i approxim ation to the $G$ ross $P$ itaevskiiequation, the initial density distribution $n(r)$ is an inverted parabola

$$
\begin{equation*}
n(r)=n_{0} 1 X_{k=1}^{"} \frac{\mathrm{r}_{\mathrm{k}}}{\mathrm{~W}_{\mathrm{k}}} 2^{\#} \tag{1}
\end{equation*}
$$

and $n(r)=0$ if the above expression is negative. H ere, $\mathrm{n}_{0}=15 \mathrm{~N}=\left(8 \mathrm{~W}_{\mathrm{x}} \mathrm{W}_{\mathrm{y}} \mathrm{W}_{\mathrm{z}}\right)$ is the peak density. The half $w$ idths along the coordinate axes $r_{k}$ are

$$
\begin{equation*}
W_{k}(0)=\frac{1}{!_{\mathrm{k}}} \quad 15 \frac{\mathrm{~h}^{2}}{\mathrm{~m}^{2}}!_{\mathrm{x}}!_{\mathrm{y}}!_{\mathrm{z}} \mathrm{a}_{\mathrm{i}} \mathrm{~N} \quad{ }^{1=5} \tag{2}
\end{equation*}
$$

$w$ here $m$ is the atom ic $m$ ass, $N$ the atom num ber in the $B E C$, and $a_{i}$ the initial scattering length before release. At time $t=0$, the trap is $s w i t c h e d o$, and a possible tim e dependence a $(t)$ m ay begin.

A ccording to Ref. [ $[1]$ 1], the BEC pro le stays a parabola during the expansion. Its widths are scaled by the param eters

$$
\begin{equation*}
\mathrm{k}(\mathrm{t})=\frac{\mathrm{W}_{\mathrm{k}}(\mathrm{t})}{\mathrm{W}_{\mathrm{k}}(0)}: \tag{3}
\end{equation*}
$$

The evolution of the scaling param eters $k$ is described by a set of coupled di erential equations, Eq. (11) in Ref. [21] ${ }^{1}$ ]. O ne can easily show that a tim e dependence of a during the expansion $m$ odi es this equation to

$$
\begin{equation*}
k=\frac{a(t)}{a_{i}} \frac{1}{x y z} \frac{!_{k}^{2}}{k}: \tag{4}
\end{equation*}
$$

The intial conditions are $k(0)=1$ and $k(0)=0 \cdot a(t)$ appears in Eq. (4, $\mathbf{I}^{-1}$ ), because the expansion is driven by the $m$ ean-eld energy which is proportional to $a(t)$. $a_{i} a p-$ pears in E q. ( $\mathbf{L}_{1}^{\prime}$ ), because $a_{i}$ determ ines the in itialw idths $W_{k}(0) w$ ith respect to which the $k$ are de ned.

A s m entioned earlier, jum ping a from its intial to its nal value $a_{f}$ takes $0: 5 \mathrm{~m} \mathrm{~s}$. We include this delay in the $m$ odel in the follow ing way

$$
\begin{array}{ll}
a(t)=\quad a_{\mathrm{f}} & 0: 5 \mathrm{~ms}<t<6 \mathrm{~m} \mathrm{~s}  \tag{5}\\
\mathrm{a}_{\mathrm{i}}=\mathrm{a}_{\mathrm{bg}} & \text { otherw ise } .
\end{array}
$$

Here, $a_{b g}$ is the background value of the scattering length far aw ay from the resonance and $t=0$ is de ned by the tum-o of the optical trap. The fact that a is switched back to $a_{b g}$ at $t=6 \mathrm{~ms}$ has little e ect, because for the param eters of the experim ent alm ost all $m$ ean- eld energy is released during the rst 6 ms (except for very sm all values of $a_{f}$ ).

The atom loss visible in Fig. ${ }^{1} 1 \mathbf{1}$ m ust also be included in the $m$ odel. This is fairly easy if it is possible $m$ ake the approxim ation that the atom loss is independent of the atom ic density. W ith this approxim ation, the shape of the BEC rem ains parabolic during the expansion. W ith a tim e dependence of the atom num ber $N$ (t), Eq. ( $\overline{4}^{-1}$ ) is then $m$ odi ed to

$$
\begin{equation*}
k_{k}=\frac{a(t) N(t)}{a_{i} N_{i}} \frac{1}{x y z} \frac{!_{k}^{2}}{k}: \tag{6}
\end{equation*}
$$

A dditionally, in Eq. (2, $\bar{L}^{\prime}$, N is replaced by the in itial value $\mathrm{N}_{\mathrm{i}}$. Since the dom inant loss $m$ echanism is actually likely to be density dependent, this approxim ation will only be reasonable if a sm all fraction of the atom $s$ is lost.

It is clear from Eq. (G) that the tim e dependence of the atom num ber is crucial. By varying the hold tim e at the nal magnetic eld from 1 to 6 ms , we experim entally checked for such a tim e dependence at $\mathrm{B}=1007: 35 \mathrm{G}$ (last_non-vanishing data point on the low - eld side in Fig. $\left.{ }_{1}^{\prime} \overline{1} 1 \mathbf{1}\right)$, but found none: $T$ he nal atom num ber was independent of the hold tim e over this range. It is hence obvious that the loss does not occur continuously during the total hold time. Instead, the loss occurs during the rst 1 m s ofhold tim e. The origin of this lossm ight be related to the form ation ofm olecules, but this is not clear. Sim ilar but w eaker loss on short tim escales w as observed for a them alcloud of atom $s$ in our previous experim ent [1]]. For sim plicity, we assum e that the atom loss occurs instantaneously at the sam e tim e as the change in a

$$
\begin{array}{ll}
\mathrm{N}(\mathrm{t})= & \begin{array}{ll}
\mathrm{N}_{\mathrm{f}} & 0: 5 \mathrm{~m} \mathrm{~s}<\mathrm{t} \\
\mathrm{~N}_{\mathrm{i}} & \text { otherw ise } .
\end{array} . \tag{7}
\end{array}
$$

For processing the data, the in itial atom num ber $\mathrm{N}_{\mathrm{i}}$ and the background value of the scattering length $a_{b g}$ are needed. $\mathrm{N}_{\mathrm{i}}$ w as determ ined from the overall absorption in a $m$ easurem ent far aw ay from the Feshbach resonance. In order to determ ine $a_{b g}$, the size of an expanded BEC far aw ay from the Feshbach resonance was

FIG.2: Scattering length as a function of $m$ agnetic eld. $T$ he solid line is a $t$ to the experim ental data ( ). The best $t$ yields $B=0: 20 \mathrm{G}$ for the w idth and $B$ peak $=1007: 40 \mathrm{G}$ for the position of the resonance. Som e experim ental data points ( ) were not included in the $t$, because they lie in the regim e of negative a where the BEC is unstable.
m easured. U sing Eqs. $(\overline{2})-(\overline{4})$ w ith $a(t)=a_{i}=a_{b g}$, the background scattering length can be extracted, yielding $a_{b g}=108(30) a_{0}$, where $a_{0}$ is the B ohr radius. This is consistent w th the theoretical value $\mathrm{a}_{\mathrm{bg}}=100: 5 \mathrm{a}_{0}$ for the state $j 1$; $1 \mathrm{i}\left[{ }_{[2}^{2} \overline{2}_{1}^{1}\right]$. For further data processing, the theoretical value was used.
$G$ iven $N_{i}$ and $a_{b g}, W_{x}(0)$ is calculated using Eq. (2) and thus the $m$ easured expanded $w$ idths $W_{x}(t)$ can be converted into $x(t)$ according to Eq. ( $\overline{3}_{1}$ I). For every data point, the observed nal atom number $\mathrm{N}_{\mathrm{f}}$ in the BEC was then used to num erically solve the coupled di erentialequations ( $(\overline{6})$ ) for the experim entally applied sequence
 experim entally observed w idth was $m$ atched.
$W$ ith this $m$ ethod, the data show $n$ in $F$ ig 11 were processed to extract the scattering length, which is shown in $F$ ig. expectation (see e.g. [23] )

$$
\begin{equation*}
\mathrm{a}=\mathrm{a}_{\mathrm{bg}} \quad 1 \quad \frac{\mathrm{~B}}{\mathrm{~B} \quad \mathrm{~B}_{\text {peak }}}: \tag{8}
\end{equation*}
$$

Here, $B$ is the width of the Feshbach resonance and $B_{\text {peak }}$ the position of the pole in $a$.

Som e data points ( in $F$ ig for the follow ing reason: A pproaching the resonance from above in $F$ ig. ${ }_{1}^{\prime \prime}$, one can see that the size of the expanded BEC decreases as expected, until at 1007.60 G (vertical line in Fig. (11) this trend is reversed. At the sam e eld, signi cant atom loss suddenly begins. W e interpret this as the onset of instability of the BEC in a regim e ofnegative scattering length 124,1226 tation is further supported by the fact that the extracted value of a shown in Fig. $\bar{n} 1$ reaches zero at this eld. For the param eters of our experim ent, the critical scattering length for instability $\left[\begin{array}{ll}1 \\ , 2 & \left.27_{1}\right]\end{array}\right]$ is $a_{\text {crit }} \quad 10^{3} \mathrm{a}_{\mathrm{bg}}$ which is alm ost zero. H ence, we conclude that the zero crossing of
$a$ is located at $B_{\text {zero }}=B_{\text {peak }}+B=1007: 60(3) \mathrm{G}$ and we use only one free param eter $B$ in our $t$. A m ore detailed analysis of the region of instability is clearly beyond the scope of this paper.

The $t$ in $F$ ig. $\bar{L}_{1}^{1}$ is in reasonable agreem ent $w$ th the experim ental data. D ata points far aw ay from the resonance are system atically too close to unity. This might be due to the fact that the $m$ agnetic eld was not held in nitely far away from the resonance before jum ping to the resonance. The best- $t$ value for the $w$ idth is $\mathrm{B}=0: 20$ (3) G, resulting in B peak $=1007: 40$ (4) G. $T$ hese values are consistent $w$ th the theoretical predictions $B^{\text {theory }}=0: 17(3) G$ and $B_{\text {peak }}^{\text {theory }}=1008: 5(1: 6) \mathrm{G}$ [1].]. $B_{\text {peak }}$ is also near the peak of the atom loss at 1007:34 (3) G m easured in Ref. 1

A $s m$ entioned in the introduction, the $m$ ethod to determ ine a described in this paper di ers slightly from the
 $m$ agnetic eld was applied while the BEC w as still in the trap and the system had tim e to equilibrate before the BEC was released from the trap. N o m atter if the expan-
 B was still on during the initial expansion), the observed

BEC size $W$ yields a / $W^{5}$. $W$ ith the $m$ ethod used in this paper, how ever, a/ $\mathrm{W}^{2}$. This is because here the initialBEC peak density $n_{i}$ is independent of $B$. Hence, the $m$ ean- eld energy ( $\mathrm{n}_{\mathrm{i}} \mathrm{a}$ ) is converted into kinetic energy, so that the nal velocity (and thus W ) is proportional to $a^{1=2}$. Therefore, $w$ th our $m$ ethod noise in the determ ination of $W$ is not ampli ed as $m$ uch when extracting a. A sim ilar technique was used in Ref. [G్ర], but there no quantitative values of a w ere extracted.

To sum $m$ arize, the $m$ ean- eld driven expansion of a BEC w as used to $m$ easure the scattering length $a$ in ${ }^{87} \mathrm{Rb}$ as a function of the $m$ agnetic eld in the vicinity of the Feshbach resonance near 1007 G . T he position and w idth of the resonance were extracted from the data. D espite the fact that the resonance is very narrow, w e have clearly dem onstrated the variation of a over a w ide range. T he range explored here is currently not lim ited by m agnetic
eld noise, but rather by fast atom loss near the resonance.
