#### Abstract

The tem perature dependence of the electron-spin resonance linew idth in $\mathrm{La}_{0: 95} \mathrm{Sr}_{0}: 05 \mathrm{M} \mathrm{nO} 3$ has been determ ined and analyzed in the param agnetic regim e across the onbital ordering transition. From the tem perature dependence and the an isotropy of linew idth and $g$-value the orbital order can be unam biguously determ ined via the $m$ ixing angle of the wave functions of the eg-doublet. The linew idth show sa sim ilar evolution $w$ ith tem perature as resonant $x$-ray scattering results.

PACS num bers: 77.22.Gm,64.70.Pf

In transition-m etal oxides the orbital degrees of freedom play an im portant role for the electric and $m$ agnetic properties. Their coupling to spin, charge and lattice is responsible for the occurrence of a variety of com plex electronic ground states. O rbital order ( O O ) can be derived via the Jahn-Teller (JT ) e ect orvia superexchange ( SE ) between degenerate orbitals under the control of strong $H$ und'srule coupling [ill ist betw een spin and orbital order and betw een $O O$ and lattice distortions, but of course a one-to-one correspondence cannot be expected. W hile spin and lattice order can easily be detected experim entally, this is not true for 00 and so far the 00 param eter rem ains hidden. In recent years resonant x-ray scattering (RX S) has been used to derive in form ation on the OO param eter $\left[\begin{array}{l}{[1]}\end{array}\right]$, but there is an ongoing dispute, whether RX S probes the JT distor-
 00 can also be derived from di raction experim ents via lattice distortions and bond lengths ${\left[\overline{5}_{1}^{\prime}\right.}_{1}^{1}$. In this Letter we dem onstrate that electron-spin resonance ( $E S R$ ) can be used to detect $O \bigcirc$ and tom onitor the evolution of the $O \bigcirc$ param eter. P robing the spin of the partially lled d-shell of $\mathrm{M}^{3+}$ ions by ESR, the anisotropy and $T$-dependence of $g$-value and linew idth $H$ provide clear inform ation on $O O$ via spin-orbit ( SO ) coupling.

The power of ESR to gain insight into OO will be dem onstrated on A type antiferrom agnetic (AFM) $\mathrm{LaM} \mathrm{nO}_{3}\left(\mathrm{~T}_{\mathrm{N}}=140 \mathrm{~K}\right)$, the parent com pound of the m agneto-resistance m anganites and a paradigm for a cooperative JT e ect that suggests a $d_{3 x^{2}} r^{2} / d_{3 y^{2}} r^{2}$-type 00 below $\mathrm{T}_{\mathrm{N}}=750 \mathrm{~K}$ [6]. H ow ever, it has been shown that SE interactions play an im portant role, too [ $\left.\bar{I}_{1}\right]$. Several recent studies exhibit clear anom alies of the ESR param eters at the JT transition in both doped and pure
 characterized by an anisotropy of $H$ [ 1 polycrystalline sam ples reduces to a broad $m$ axim um in

H and the resonance eld H res had been analyzed for 200 K and 300 K in high-tem perature approxim ation, al-
low ing to estim ate the $D$ zyaloshinsky $M$ oriya (D M ) interaction and the strength of the zero- eld splitting (ZFS) param eters [1] ]. AtX B and frequencies ( 9 GHz ) H was of the sam e order of $m$ agnitude as $\mathrm{H}_{\text {res }}$ and due to the overlap with the resonance at $H_{\text {res }}$ and their mutual coupling via the nondiagonal elem ents of the dynam ic susceptibility [1] [] the values for $H$ res contained a rather large uncertainty. To avoid these problem swe perform ed new experim ents at $Q$ boand frequencies ( 34 GHz ), which allow ed a better determ ination of $H$ res.

The scope of the present paper is the com prehensive analysis of the $T$-dependence and anisotropy of $H$ and the g -value of the ESR signal in $\mathrm{La}_{0: 95} \mathrm{Sr}_{0}: 05 \mathrm{M} \mathrm{nO} 3 . \mathrm{We}$ chose this concentration for the present study as an untw inned single crystal was available and $T_{\text {JT }} 605 \mathrm{~K}$ is accessible to our experim ental setup [15].
$N$ ew ESR $m$ easurem entsw ere perform ed w ith a B ruker ELEXSYS E500 CW spectrom eter at Q B and frequencies ( $34 \mathrm{GHz}, 42 \mathrm{~K}$ T 290 K ), using a continuous gas- ow cryostat for He ( O xford ). The oriented sam ple was mounted in a quartz tube w ith para n. A gon iom eter allow ed the rotation of the sam ple around an axis perpendicular to the static $m$ agnetic eld $\mathrm{H}_{\text {ext }}$.
$F$ igure ${ }_{1}^{111}$, show S for X -band frequency and $F$ ig.
$H$ and the e ective $g$-value $g_{e}=h=\left({ }_{\mathrm{B}} \mathrm{H}_{\text {res }}\right)$ deter$m$ ined from $H$ res for $Q$ boand frequency. The observed linew idths at both frequencies nigely coincide. O nly near them inim um below 200 K the absolute values are slightly enhanced at 34 GHz as com pared to 9 GHz . Whereas the $g$-values obtained at $X$-band frequency bear a rather large uncertainty $[1], ~ " 1]$ values show a regular $T$-dependence, approaching a constant high-tem perature value and increasing for $T$ ! $T_{N}$. $F$ irst, we determ ined the ZFS param eters $D$ and $E$ from the $T$ dependence of $H$ res at $Q$ boand frequency. U sing the general form ula for the resonance shifl due to crystal
 tation (angle) of the $\mathrm{M} \mathrm{nO}_{6}$ octahedra in the ac plane (axis notation like in Ref. $17_{1} 7_{1}$ ), we obtained the follow ing expressions for the e ective $g$-values for $\mathrm{H}_{\text {ext }}$ applied

FIG. 1: H ( T ) in $\mathrm{La}_{0: 95} \mathrm{Sr}_{0}: 05 \mathrm{M} \mathrm{nO}_{3}$ at $\mathrm{X}-\mathrm{B}$ and frequency for $H_{\text {ext }}$ applied parallel to the three $m$ ain axes of the orthorhombic structure. Solid and dashed lines represent ts using eq. (2) as described in the text.
along one of the crystallographic axes

$$
\begin{array}{ll}
\frac{g_{a ; c}^{e}(T)}{g_{a ; c}} & 1+\frac{D}{T} T_{C W}
\end{array}\left[\begin{array}{lll}
(3 & 1) & 3(1+) \sin (2)
\end{array}\right]
$$

w ith the Curie W eiss ( CW ) tem perature $\mathrm{T}_{\mathrm{CW}}$ and $=$ $E=D$. All term $s$ of second and higher order in $D=(T$ $\mathrm{T}_{\mathrm{C} W}$ ) were neglected. T he T -dependence of the e ective $g$-values is, hence, given by the CW law of the magnetic susceptibility. Excluding the critical regim e on approaching $m$ agnetic order below 170 K , the data are well described by this approach (solid lines in Fig. (2) , where $T_{C w}$ was kept xed at 111 K [1] $]$. The rotation angle was chosen as $=13$ as observed in pure
 scribed by $D=0: 60(2) K$, the $E=D$ ratio $=0.37(1)$, and the $g$-values $g_{a}=1.988(1), g_{b}=1.986(1)$, and $g_{c}=1.984(1)$. From these crystallographic $g$-values, the local $g$ values of $\mathrm{M}^{3+}$ can be calculated as $g_{z}=1.977, g_{y}\left(=g_{b}\right)=1.986$, and $g_{x}=1.995$, typical for ions w th less than half- lled 3d-shell w th the longest and shortest $\mathrm{M} \mathrm{n}-\mathrm{O}$ bond along the local $z$ and $x$ direction, respectively [18].
$T$ he $m$ ain result of this evaluation is the $E=D$ ratio, which we im proved in com parison to our previous estim ate $[1]-1]$ by the $Q$ band experim ent. For $H_{\text {ext }}$ applied along the b-axis the data are nearly T -independent, whereas they clearly exhibit the CW behavior for the other orientations. Regarding the equation for $g_{b}$, this is
only possible, if the factor (3 1) is close to zero and hence $\quad 1=3$. This result is independent on the value of the rotation angle. Only the absolute value of $D$ directly depends on the choioe of , which accounts for the splitting of the resonance eldsbetw een a and cdirection.
$W$ ith the obtained $E=D$ ratio we now tum to the evaluation of the linew idth data. A detailed derivation of the CF contributions to the ESR linew idth in the cooperative JT distorted perovskite structure accounting for the m utual rotations of the $\mathrm{M} \mathrm{nO}_{6}$ octahedra is presented in $R$ ef. ${ }_{1}^{11} \underline{1}_{1}^{\prime}$. These theoretical considerations can be sum m arized in the follow ing form ula

$$
\begin{align*}
& \mathrm{H}^{\left(\# ;^{\prime}\right)}(\mathrm{T})=\frac{\mathrm{T} \mathrm{~T}_{\mathrm{CW}}}{\mathrm{~T}}[\mathrm{DM}(1)+  \tag{2}\\
& +1{\frac{T}{T_{J T}}}^{2}\left({ }_{C F}(1) f_{\text {reg }}^{\left(\# \prime^{\prime}\right)}\right. \\
& \left.\left.+\operatorname{CFD} \frac{\mathrm{T}_{\mathrm{N}}}{6\left(\mathrm{~T} \mathrm{~T}_{\mathrm{N}}\right)} \quad \mathrm{f}_{\text {div }}^{\left(\# \text {; }^{\prime}\right)}\right)\right] ;
\end{align*}
$$

where the rst term describes the contribution DM_ (1) oftheD M interaction as introduced by H uberet al. [id sum ing that the exchange constants are T -independent. This contribution is expected to survive the JT transition and hence to determ ine the line broadening also at $\mathrm{T}>\mathrm{T}_{\mathrm{JT}}$. The second and third term, CF and CFD, represent the regular and divergent $C F$ contributions, respectively. O nly the latter diverges for $T!T_{N} w$ ith an exponent, whereas both term $s$ decrease for $T$ ! $T_{J T}$ w th a critical exponent 2 , $w$ th being the criticalexponent of the ZFS param eters D and E. N ote that both the assum ption of $T$ independent exchange constants and the application of the criticality at $\mathrm{T}_{\text {Jт }}$ throughout the entire param agnetic $0^{0}$-phase can in uence the value of the criticalexponent which therefore has to be regarded cautiously. The angular factors $\mathrm{f}_{\text {reg }}^{\left(\# ;^{\prime}\right)}$ and $\mathrm{f}_{\text {div }}^{\left(\#^{\prime \prime}\right)}$ read

$$
\begin{aligned}
\mathrm{f}_{\text {reg }}^{\left(\# ; ;^{\prime}\right)} & =\mathrm{f}_{\mathrm{div}}+(1+)^{2}\left(1+\frac{3}{2} \sin ^{2} \#\right) ; \\
\mathrm{f}_{\mathrm{div}}^{\left(\# ;^{\prime}\right)} & =\frac{1}{2}\left[\begin{array}{llll}
1 & 3+2(1+)^{3}(1 & \sin ^{2} \# \sin ^{2} \prime
\end{array}\right) \\
& +\frac{1}{2}\left[\begin{array}{llll}
1 & 3 & (1+)\}(1 & \left.\sin ^{2} \# \cos ^{2} \prime\right) ;
\end{array}\right.
\end{aligned}
$$

where \# and ' are the polar and azim uthal angles betw een $\mathrm{H}_{\text {ext }}$ and the crystallographic b and c axes, respectively. An analogous calculation to the one presented in $\left[1 \underline{1}_{1}^{\prime} \underline{1}_{1}^{\prime}\right]$ show ed that the DM interaction does not exhibit any critical behavior at $T_{N}$. To $m$ inim ize the num ber of $t$ param eters, we neglected here any angular dependenœ of the DM contribution. In rst approxim ation this is justi ed by the observation that above $T_{J T}$ the linew idth is isotropic. H ow ever, generally an anisotropy of the DM contribution can arise in the orbitally ordered state [1] butions from di erent $\mathrm{Mn}-\mathrm{O}-\mathrm{M} \mathrm{n}$ bond geom etries, and

FIG.2: $H$ ( $T$ ) and e ective $g$-value $g e(T)$ at $Q$ boand frequency for $\mathrm{H}_{\text {ext }}$ applied parallel to the three crystallograph ic axes of the orthorhom bic structure. T he solid lines represent
ts using eq. ( $\mathrm{I}_{4}$ ) for $g_{e}$, the dashed lines for $H$ are the sam $e$ as in $F i g .{ }_{2}$.
its transform ation to an isotropic behavior on approaching $T_{\text {JT }}$ needs further theoretical considerations. In the m in im alm odelwe om itted the divergent C $F$ contribution ( $C F D=0$ ) and tried to nd the best $t$ for the linew idth data. The characteristic tem peratures were kept xed at $\mathrm{T}_{\mathrm{CW}}=111 \mathrm{~K}$ and $\mathrm{T}_{\mathrm{JT}}=605 \mathrm{~K}$ and the rotation angle in the ac plane was set to $=13$. In addition the param eter $=0.37 \mathrm{w}$ as taken from the evaluation of the $g$-values. So only three $t$ param eters rem ain, as there are the regular part of the CF contribution CF (1), its criticalexponent at the JT transition, and the DM contribution DM (1), which survives also at tem peratures $T>T_{\text {JT }}$. A sim ultaneous $t$ (solid lines in $\left.F i g .{ }^{-1 / 1}\right)$ ) of the $T$-dependence of $H$ is satisfactorily perform ed above 200 K w th $\mathrm{DM}(1)=1.0(1) \mathrm{kOe} \mathrm{Cf}(1)=0.57(2) \mathrm{kO} \mathrm{e}$, and $=0.16(1)$.
$F$ inally, we added the e ect of the divergent C F contribution, which allow s to increase the di erence betw een
H a and H c to lower tem peratures, as observed in the experim ent. A s shown in Fig. '11 (dashed lines) a satisfactory qualitative description of the data was obtained by
CFD $=10 \mathrm{kO} \mathrm{e}$ and $=1.8 \mathrm{w}$ th xed $\mathrm{T}_{\mathrm{N}}=135 \mathrm{~K} . \mathrm{Compar}-$ ison $w$ ith the $Q$ boand data $F$ ig. netic critical exponent below 200 K rather tums to the theoretically expected low er value of $=0.75$ [19.1, which how ever is not applicable at higher tem peratures. T he reason is that the $t$ function is used for the whole tem perature range, but the derivation of the pow er law only holds for tem peratures close to $T_{N}$. A further im prove$m$ ent $m$ ay be achieved by taking into account the sym -
$m$ etric anisotropic exchange interaction, which is beyond the scope of this paper. In the follow ing we concentrate on the inform ation obtained from the regularpart of $H$.

The DM contribution $\quad$ M ( 1 ) $=1.0 \mathrm{kO}$ e determ ined in the $O^{0}$-phase is lower than the one expected from
H 1.4 kOe in the O -phase. This discrepancy can be explained by linew idth contributions of the CF due to the dynam ic JT e ect present in the $O$-phase [20']. C om parison w ith the regular CF contribution CF (1) $=0.57 \mathrm{kO}$ e allow s to estim ate the averaged value $D_{D M}$ of the DM interaction as de ned in Ref. $T$ he ratio of the linew idth contributions equals the ratio of the respective second $m$ om ents approxim ated by
 obtains $D_{D M} 025 \mathrm{~K}$. These values are free from the uncertainty in the estim ation of the exchange frequency in the exchange-narrowed linew idth [1][], because we used the $g$-values to determ ine the absolute values. $T$ hey are sm aller than the values estim ated earlier for polycrystalline $\mathrm{LaM} \mathrm{nO}_{3}$ but their relative strength is in good

A fter having extracted the ZF S param eters wew illnow discuss the consequences for OO in $\mathrm{LaMnO}_{3}$ :
In Fig. 'ī1 (a) the reduced ESR linew idth $H$ a $T=(T$ $\mathrm{T}_{\mathrm{C}}$ ) for $\mathrm{H}_{\text {ext }}$ parallel to the a-axis, which bears the criticalbehavior on approaching $\mathrm{T}_{\text {JT }}$ (see eq. $\overline{\mathrm{In}}$ ), and the RXS intensity obtained by M urakam iet al. $[$ [ $]$ for $\mathrm{LaM} \mathrm{nO}_{3}$ are show $n$ to visualize the sim ilarity of the tw o quantities on approaching both $T_{N}$ and $T_{\text {JT }}$. N ote that we used the xed value $T_{C W}=111 \mathrm{~K}$ of the $O^{0}-$ phase leading to som $e^{-}$ what lower values for the 0 -phase. It has been pointed out that the RXS intensity close to $T_{J T}$ is / ( $\left.1 \quad T=T_{J T}\right)^{2}$ [4] ram eter given by the pseudo spin $T=1=2(\sin ; 0 ; 00 s)$
 $m$ ixing of the $w a v e$ functions of the $e_{g}$-doublet in the ground state $g=C_{1} j 3 z^{2} \quad r^{2} i+c_{2} \dot{x}^{2} \quad y^{2} i$. To compare the results of RXS and ESR we tted the RXS data in the vicinity of the JT transition ( $650 \mathrm{~K} \quad \mathrm{~T} \mathrm{~T}_{\mathrm{JT}}=780 \mathrm{~K}$ ) w ith such a critical behavior (solid line in Fig. İ-1 (a)) and obtained an exponent $=0: 16(1)$ in agreem ent w ith the ESR linew idth. Considering that the ZFS param eters can be denoted as $D=3\left(+{ }^{2}=\right)$ cos and $\mathrm{E}=\overline{3}\left(+{ }^{2}=\right) \sin$ w ith the spin-spin coupling , the SO coupling and the $\mathrm{t}_{2 g}-e_{\mathrm{g}}$ splitting energy [ it is easy to identify the relation w ith the OO param eter $\mathbb{T}$. D espite the lack of data in the critical regim e, $F$ ig. . determ ined from a neutron di raction (ND) study by R odriguez-C arjaval et al. tained by using $\mathrm{K}\left(1 \quad \mathrm{~T}=\mathrm{T}_{\mathrm{JT}}\right)^{=2}+2^{1=2} \quad\left(\mathrm{~T}_{\mathrm{JT}}=750 \mathrm{~K}\right)$ w th a critical exponent $=2$ provided by $D /\left(\begin{array}{ll}c_{1}^{2} & c_{2}^{2}\end{array}\right)$ and $E / C_{1} \quad \mathbb{E} . W$ th $K_{1}=0.10$ and $K_{2}=-0.12$ the data for $C_{1}$ and $c_{2}$ can be well described throughout the JT distorted phase. H ow ever, attem pting to describe the three

F IG . 3: T-dependence of (a) the reduced ESR linew idth in $\mathrm{La}_{0}: 95 \mathrm{Sr}_{0}: 05 \mathrm{M} \mathrm{nO}_{3}$ com pared to the RXS intensity of $\mathrm{LaM} \mathrm{nO}_{3}$ taken from ['] described in the text. Inset: -dependence of the nom alized optical spectral weight $\mathrm{I}_{\mathrm{c}}=\mathrm{I}_{\mathrm{ab}}$ follow ing [21.1] (solid line) with the experim entally derived -values; (b) $\bar{T}$-dependence of $c_{1}$ and $C_{2}$ determ ined by ND taken from [1]. The dashed lines were obtained using $K\left(1 \quad T=T_{\text {JT }}\right)^{=2}+2^{1=2}$.
data points in the critical regim e rather suggest 0.3 . O nly a detailed structural study in the critical regim e w ill allow a direct con m ation of the critical exponent for $c_{1}$ and $c_{2}$, but $=2=0.08$ seem $s$ to yield a reasonable description.

The $m$ ain result of this study is to estim ate the angle $=\overline{3} \arctan (E=D)$ and determ ine the type of $O O$ by using the obtained value $\mathrm{E}=\mathrm{D}=0.37(1)$, which after taking into account the transform ation to a local coordinate system [1"d results in ESR 92 . A nother estim ate has been obtained from ND via the orbitalm ixing coe cents at room tem perature $c_{1} \quad 0.8$ and $c_{2} \quad 0.6$ resulting in $\mathrm{ND}=106$ [5్త-]. This discrepancy cannot easily be explained. H ow ever, Tobe et al tried to explain the anisotropy of the opticalconductivity in $\mathrm{LaM} \mathrm{nO}_{3}$ on the basis of a $p \quad d$ transition $m$ odel by using the ratio $I_{c}=I_{a b}=2(1 \quad \cos )=(2+\cos )$ (see inset of $F$ ig. $\left.3_{1}^{-1}(a)\right)$ betw een the optical spectral weight $w$ th the polarization w ithin the ferrom agnetic (FM) plane (there ab) and along the AFM axis (there c). $\left.\left.{ }^{2}\right]_{1}^{1}\right]$ Their simple m odel suggests a value 74 to describe the experim ental value of $\mathrm{I}_{\mathrm{c}}=\mathrm{I}_{\mathrm{ab}}=0.6$ at 10 K in the AFM regim e. Theoretically, only a slight decrease of below $T_{N}$ is expected
$[\underline{[1]}, 12 \overline{2} \overline{2} \overline{2}]$ and therefore above $T_{N}$ ESR 92 yields a better description of the anisotropic properties of $\mathrm{LaM} \mathrm{nO}_{3}$ in the orbitally ordered state than wd 106 . A lejandro et al derived a sim ilar $E=D$-value from $E S R$ data in $\mathrm{La}_{7=8} \mathrm{Sr}_{1=8} \mathrm{M} \mathrm{nO}_{3}\left[{ }^{-1}\right]$ which con m s our result. To the best of our know ledge no -estim ate has been obtained by RXS and it is worthw hile to note that the RXS intensity becom es $m$ axim al for $=2$ [ $\overline{4}]$, the value obtained by ESR. Follow ing [231] $==2$ characterizes 00 stabilized by the SE processes in the FM bonds and the electron-phonon coupling is sm all com pared to the bandw idth. R ecent calculations suggest $=2$ at $\mathrm{T}=\mathrm{T}_{\mathrm{N}}$ and $=83$ at $\mathrm{T}=0$ and con m our ndings [22 2 .
In sum $m$ ary, we were able to determ ine unam biguously the orbital order of $\mathrm{La}_{0}: 95 \mathrm{Sr}_{0}: 05 \mathrm{M} \mathrm{nO} 3$. The evolution of the OO param eterm onitored by the RXS intensity show s an intriguing sim ilarity to the ESR linew idth. W e found am ixing angle $=92$ suggesting that O O is dom inated by $S E$ coupling in agreem ent $w$ ith theoreticalpredictions.
