# M icroscopic W ave Functions of Spin Singlet and N em atic M ott States of Spin-O ne B osons in H igh D im ensional B ipartite Lattices 

M ichiel Snoek and Fei Zhou<br>IT P, U trecht U niversity, M innaert building, Leuvenlaan 4, 3584 CE U trecht, $T$ he $N$ etherlands<br>(D ated: January 7, 2022)

#### Abstract

W e present $m$ icroscopic wave functions of spin singlet $M$ ott insulating states and nem atic M ott insulating states. We also investigate quantum phase transitions between the spin singlet $M$ ott phase and the nem atic $M$ ott phase in both large-N lim it and small-N lim it $\mathbb{N}$ being the num ber of particles per site) in high dim ensional bipartite lattices. In the $m$ ean eld approxim ation em ployed in this article we nd that phase transitions are generally weakly rst order.

## I. IN TRODUCTION

## II. ALGEBRA AND SETTING

A. Them icroscopic $H$ am iltonian in the dilute lim it

The recent observation of correlated states of boscm${ }^{-}$-om s in optical lattices has generated m uch interes A s known for a while, when bosons in lattioes interact w ith each other repulsively, they can be localiz form a M ott insulating state instead of a condensat $T$ his phenom enon has been observed in the optical lattice experim ent. By varying laser intensities of optical lattices, $G$ reiner et al. have successfiully investigated $M$ ott states of spinless bosons by probing spin polarize ${ }^{-1}$ atom $s$ in opticallatticesw ith a large potentialdept

W e are interested in spin correlated M ott insulating states of spin-one bosons, especially spin-one bosons w ith antiferrom agnetic interactions. Som e aspects of spin correlated M ott insulating states w ere investigated recently. For an even num ber of particles per site, both spin singlet M ott insulators and nem atic M ott insulators were found in certain param eter regim es, while for high di$m$ ensional lattices $w$ th an odd num ber of partirn per site only nem atic insulating states were proposec . In one-dim ensional lattioes, it was dem onstrated that for an odd num ber of particles per site, $M$ ott states should be dim erized valence-bond-crystals, wher support interesting fractionalized quasi-excitation E ects of spin correlations on $M$ ott insulator-super ula transit shave been studied and rem ain to be fully understoo

In this article, we analyse the $m$ icroscopic structures of spin singlet M ott insulating states (SSM I) and nem atic M ott insulating states (NM I). W e study, quantitatively, quantum phase transitions betw een these two phases in high-dim ensionalbipartite lattioes. In the m ean eld approxim ation, we dem onstrate that for an even num ber of particles per site, the transitions are weakly rst order. The organisation is as follow s. In section II, we present the general setting for the study of spin order-disorder quantum phase transitions. In section III, we present $m$ ean eld results on the quantum phase transitions in both sm all N and large N lim its. In section IV, we discuss issues which are to be understood in the future.

The microscopic lattice H am iltonian we em ploy to study spin correlated states of spin-one bosons is:

$$
\begin{aligned}
& \left.H_{m \text { icroscopic }}=\mathrm{t}^{\mathrm{X}} \underset{\mathrm{k} ; \mathrm{m}}{\mathrm{y}} \quad \underset{\mathrm{l}, \mathrm{~m}}{ }+\mathrm{h.c.}\right) \\
& \mathrm{X}^{\mathrm{hk} \mathrm{li}}
\end{aligned}
$$

$$
\begin{aligned}
& X^{k ; 1} \\
& +\underset{k ; 1}{X} \underset{k ; m}{y} S_{m n} \operatorname{kn}^{S}(k ; 1) \underset{1 ; m}{y} 0 S_{m} 0_{n} 0 \quad \ln n^{0}
\end{aligned}
$$

Here $\underset{k ; m}{\mathrm{y}}$ is the creation operator of a spin-one particle at site $\mathrm{k} w$ ith spin-index $\mathrm{m}=0$; 1 . hkli indicates that the sum should be taken over nearest neighbours and $S$ ( = x;y;z) are spin-one $m$ atrix operators given as:
$\mathrm{U}(\mathrm{k} ; \mathrm{l})$ and $\mathrm{U}^{\mathrm{s}}(\mathrm{k} ; \mathrm{l})$ are, respectively, spin-independent and spin-dependent interaction param eters betw een two bosons at site k and 1 .

In the dilute lim it, which is de ned as a lim it where $a^{3} \quad 1$ ( $a$ is the scattering length and the average density), atom s scatter in s-w ave channels. For tw o spinone atom s , the scattering takes place in the totalspin $\mathrm{S}=$ $0 ; 2$ channels, w th scattering lengths $a_{0 ; 2}$. Interactions betw een atom s can approxim ated as spin-dependent contact interactions. In the lattice $m$ odel introduced here, calculations yleda

$$
\begin{equation*}
U(k ; 1)=E_{c k l} \text { and } U^{S}(k ; 1)=E_{s k l}: \tag{2}
\end{equation*}
$$

The param eters $E_{c}$ and $E_{s}$ are given by:

$$
\begin{equation*}
E_{c}=\frac{4 \sim^{2}\left(2 a_{2}+a_{0}\right)}{3 \mathrm{M} \mathrm{~N}} e ; \quad E_{s}=\frac{4 \sim^{2}\left(a_{2} \quad a_{0}\right)}{3 \mathrm{M} \mathrm{~N}} e_{;} \tag{3}
\end{equation*}
$$

$w$ here $N$ is the average num ber of atom s per site, $M$ is the $m$ ass of atom $s$ and $e$ is a constant.

For the study of spin correlated states in lattices, it is rather convenient to introduce the follow ing operators:

$$
\begin{align*}
& \underset{k ; x}{y}=\frac{1}{P_{\overline{2}}^{1}}\left(\begin{array}{c}
\underset{k}{y} ; 1
\end{array} \underset{k ; 1}{y}\right)  \tag{4a}\\
& \underset{k ; y}{y}=\frac{i}{\mathrm{i}_{2}}\left(\begin{array}{l}
\mathrm{y} \\
\mathrm{k} ; 1
\end{array}+\underset{\mathrm{k} ; 1}{\mathrm{y}}\right)  \tag{4b}\\
& \underset{\mathrm{k} ; \mathrm{z}}{\mathrm{y}}=\underset{\mathrm{k} ; 0}{\mathrm{y}} \tag{4c}
\end{align*}
$$

where $k$ again labels a lattice site. In this representation:

$$
\begin{equation*}
\underset{\mathrm{k} ; \mathrm{m}}{\mathrm{y}} \mathrm{~S}_{\mathrm{mn}} \mathrm{k} ; \mathrm{n}=\hat{S}_{\mathrm{k}} \quad \text { i } \quad \underset{\mathrm{k} ;}{\mathrm{y}} \underset{\mathrm{k} ;}{\mathrm{k}} \tag{5}
\end{equation*}
$$

; ; 2 fx;y;zg. The density operator can be expressed in a usualway:

$$
\begin{equation*}
\hat{\mathrm{k}}_{\mathrm{k}}^{\mathrm{y}} \quad \mathrm{y}_{\mathrm{k}} ; \mathrm{k} ;: ~: ~ \tag{6}
\end{equation*}
$$

C onsequently the H am iltonian is given as:
where we have introduced the chem ical potential ; $\hat{S}_{k}^{2}$ is the total spin operator $\hat{S}_{k} ; \hat{S}_{k}$;
k; ( $=x ; y ; z$ ) are bosonic operators obeying the follow ing com $m$ utation relations:

Taking into account Eqs. 5,6,8, one can verify the follow ing algebras:

$$
\begin{align*}
& {\left[\hat{\mathrm{S}}_{\mathrm{k}} ; 1 ;\right]={ }_{\mathrm{kli}} \mathrm{i}_{\mathrm{k}} \quad \mathrm{k}}  \tag{9a}\\
& {\left[\hat{S}_{k} ; \frac{y}{1} ;\right]={ }_{k 1}{ }^{i} \quad \stackrel{y}{k} ;}  \tag{9b}\\
& {\left[\hat{S}_{k} ; \hat{S}_{1}\right]={ }_{k l i} \quad \hat{S}_{k}}  \tag{9c}\\
& {\left[\hat{k}_{k} \mathrm{l} ; \mathrm{]}=\mathrm{kl} \mathrm{k}\right. \text {; }} \tag{9d}
\end{align*}
$$

$$
\begin{align*}
& {\left[\hat{\mathrm{S}}_{\mathrm{k}} ;{ }^{\wedge}{ }_{\mathrm{l}}\right]=0} \tag{9f}
\end{align*}
$$

O f particular interest is the singlet creation operator

$$
\begin{equation*}
P_{\overline{6}}^{1} \underset{\mathrm{k} ;}{\mathrm{y}} \underset{\mathrm{k} ;}{\mathrm{y}}=\mathrm{P}_{\overline{6}}^{1}(\underset{\mathrm{k} ; 0}{\mathrm{y}} \underset{\mathrm{k} ; 0}{\mathrm{y}} \quad 2 \underset{\mathrm{k} ; 1}{\mathrm{y}} \underset{\mathrm{k} ; 1}{\mathrm{y}}): \tag{10}
\end{equation*}
$$

We nd the follow ing properties for this operator:

$$
\begin{align*}
& \text { [k; k; ; } \underset{1}{\mathrm{y}} \text {; }]=2 \mathrm{kl} \mathrm{k} \text {; ; } \tag{11a}
\end{align*}
$$

C. The on-site dynam ics

The total spin operator can be expressed as:

$$
\begin{equation*}
\hat{S}_{\mathrm{k}}^{2}=\hat{\mathrm{k}}_{\mathrm{k}}\left(\hat{k}_{\mathrm{k}}+1\right) \quad \underset{\mathrm{k}}{\mathrm{y}} ; \underset{\mathrm{k}}{\mathrm{y}} \mathrm{y} \quad \mathrm{k} ; \mathrm{k} ;: \tag{12}
\end{equation*}
$$

So, eigenstates of the total spin operator have to be eigenstates of the "singlet counting operator" $\begin{array}{llll}\mathrm{y} & \mathrm{y} & \mathrm{k} & \mathrm{k} \text {; } \mathrm{k} \text {; } .\end{array}$
De ning the state $\mathrm{n}_{\mathrm{k} ; 0}$ such that:

$$
\begin{equation*}
\hat{\mathrm{k}} \underset{\mathrm{k} ; 0}{\mathrm{n}}=\mathrm{n} \underset{\mathrm{k} ; 0}{\mathrm{n}} ; \quad \underset{\mathrm{k}}{\mathrm{y} ;} \underset{\mathrm{k} ;}{\mathrm{y} ;} \mathrm{k} ; \quad \mathrm{k} ; \quad \underset{\mathrm{k} ; 0}{\mathrm{n}}=0 \text {; } \tag{13}
\end{equation*}
$$

we nd that wave functions of these eigenstates are:
where C is a norm alization constant. From Eq.五 follow s that:

$$
\begin{array}{lll}
\mathrm{y}  \tag{15}\\
\mathrm{k} ; & \mathrm{y} \\
\mathrm{k} & \mathrm{k} ; & \mathrm{k} ; \\
\mathrm{k} ; \mathrm{m} \\
\mathrm{n} \\
\mathrm{k}
\end{array}(4 \mathrm{~m}(\mathrm{n} \quad \mathrm{~m})+2 \mathrm{~m}) \underset{\mathrm{k} ; \mathrm{m}}{\mathrm{n}}
$$

U sing that $\hat{k}_{k}{\underset{k}{k}, \mathrm{~m}}_{\mathrm{n}}^{\mathrm{n}}=\mathrm{n} \underset{\mathrm{k} ; \mathrm{m}}{\mathrm{n}}$ we derive:

$$
\begin{equation*}
\hat{S}_{\mathrm{k}}^{2} \underset{\mathrm{k} ; \mathrm{m}}{\mathrm{n}}=(\mathrm{n} \quad 2 \mathrm{~m})(\mathrm{n} \quad 2 \mathrm{~m}+1)_{\mathrm{k} ; \mathrm{m}}^{\mathrm{n}}: \tag{16}
\end{equation*}
$$

So $S_{k}=n \quad 2 m$. Now if $n$ is even, $S_{k}$ is also even and when n is odd, $\mathrm{S}_{\mathrm{k}}$ is odd too. For an even num ber of particles per site N the excitations labelled by $S_{k}=0 ; 2 ; 4 ;::: ; \mathrm{N}$ are present, whereas for an odd num ber of particles per site $S_{k}=1 ; 3 ; 5 ;::: ; \mathrm{N}$ are allowed. $T$ his re ects the basic property of the $m$ any body wave function of spin-one bosons, which has to be sym $m$ etric under the interchange of tw o particles.

Solutions for spin correlated condensates ${ }^{-1 / 2}$ nite num bers of particles were previously obtaine in the them odynam these states evolve into polar condensates A lso there, tw o-body scatterings w ere shown to leaa to either "antiferrom agnetic" or "ferrom agnetic" spin correlations in condensates. Spin corre] densates have been investigated in experi$m$ ents

## D. The e ective $H$ am iltonian for $M$ ott states

In the lim it when $t \quad E_{c}$, atom $s$ are localized and only virtualexchange processes are allow ed. A n e ective H am iltonian in this lim it can be derived in a second omler perturbative calculation of the $H$ am iltonian in Eq

Here $J_{\text {ex }}=\frac{t^{2}}{2 E_{c}}$. In deriving Eq we have taken into account that $\mathrm{E}_{\mathrm{s}} \quad \mathrm{E}_{\mathrm{C}}$.

To facilitate discussions, we introduce the follow ing operator:

$$
\begin{equation*}
\hat{Q}_{\mathrm{k}} ;=\underset{\mathrm{k}}{\mathrm{y}} \quad \mathrm{k} ; \quad \frac{1}{3} \underset{\mathrm{k}}{\mathrm{y}} ; \mathrm{k} ; ~ ; \tag{18}
\end{equation*}
$$

whose expectation value

$$
\begin{equation*}
\widetilde{Q}=\frac{h \hat{Q} \quad i}{h \hat{Q} \quad i_{\text {ref }}} \tag{19}
\end{equation*}
$$

is the nem atic order param eter. T he reference state ${ }_{\text {ref }}=\frac{\left(n_{p} \frac{)^{N}}{\mathrm{~N}!}\right.}{}$ jvaci is a m axim ally ordered state. C hoosing $n=e_{z}$, we obtain:

$$
\begin{array}{lllll} 
& 0 & 0 & i_{\text {ref }}=\mathrm{N} @ & 0^{\frac{1}{3}}  \tag{20}\\
0^{0} & 0^{1} \\
0 & 0^{\frac{1}{3}} & 0 & \frac{2}{3}
\end{array}:
$$

$Q$ varies in a range of $\left[\frac{1}{2} ; 1\right]$.
In term softhe operator $\hat{Q}$, thee ective $M$ ott $H$ am iltonian can be rew ritten as (up to an energy shift):

Finally we de ne

$$
\begin{equation*}
=\frac{\mathrm{zJ} \mathrm{Jex}_{\mathrm{e}}}{\mathrm{E}_{\mathrm{s}}} \tag{22}
\end{equation*}
$$

as a dim ensionless param eter, which can be varied continuously; $z$ is the coordination num ber of the lattice.
E. The range of the physical param eters

From Eq. it is clear that $E_{s}$ and $E_{c}$ depend on the density, number of atom $s$, the $m$ ass of atom $s$ and scattering lenghts. H owever, their ratio depends only on th ing lengths. A ccording to current esti$m$ ates for sodium atom $s$ this ratio is given as $\frac{E_{s}}{E_{c}} \quad 10$. In this paper, we are interested in the lim it $E_{S} \quad E_{C}$.

The param etert can be varied independently by changing the depth ofthe opticallattice. A w ide range is experim entally accessible; one can vary from the regim e where e $E_{c}$ to a regim ewhere e $E_{s}$. We lim it ourselves to M ott states ( $\left(\mathrm{E}_{\mathrm{c}}\right.$ ), where allbosons are localized, but the ratio can have arbitrary values.
III. PHASE TRANSIT IONS BETW EEN SSM I'S

AND NM I'S
A. Two particles per site

In the case oftw o particles per site , the on-site H ilbert space is six-dim ensional, including a spin singlet state

$$
\begin{equation*}
j S=0 ; S_{z}=0 i=\frac{y^{y} y}{\overline{6}} j 0 i ; \tag{23}
\end{equation*}
$$

and ve spin $S=2$-states

$$
\begin{equation*}
\text { Q } \quad i=\frac{P_{\overline{3}}}{2} Q \quad \text { y } \quad y_{j 0 i} \tag{24}
\end{equation*}
$$

where $Q \quad$ is a sym $m$ etric and traceless tensor $w$ ith ve independent elem ents. A llstates in the H illbert space are sym $m$ etric under the interchange ofbosons; as expected, the states $\mathbb{Z} i$ are orthogonal to $T S=0 ; S_{z}=0 i$. It is convenient to choose the follow ing representation of :

$$
\begin{equation*}
Q \quad(\mathrm{n})=\mathrm{n} \mathrm{n} \quad \frac{1}{3} \quad ; \tag{25}
\end{equation*}
$$

w th the director n as a unit vector living on $S^{2}$. States de ned by the director $n$ form an over-com plete set in the subspace spanned by ve $S=2$ states.

W hen the honping is zero, one notioes that the H am irtonian in E
function is $\quad$ om m utesw ith $\hat{\mathrm{S}}_{\mathrm{k}}^{2}$; the ground state w ave function is

$$
j i={ }_{k}^{Y} j=0 ; S_{z}=0 i_{k}:
$$

On the other hand, when $\mathrm{E}_{\mathrm{s}}$ goes to zero, the H am iltonian com $m$ utesw ith $\operatorname{Tr}\left[\hat{Q_{k}} ; \hat{\hat{Q}_{1}} ; \quad\right]$ and the ground state wave function can be con m ed as:

$$
\begin{equation*}
j i=Y_{k}^{r} \frac{2}{3} \mathbb{Q}(n) i_{k}+P^{1} \frac{1}{3} \mathcal{S}=0 ; S_{z}=0 i_{k}: \tag{27}
\end{equation*}
$$

for any choice of the director $n$.
To study spin nem atic or spin singlet $M$ ott states at an arbitrary, we introduce a trialw ave function which is a linear supenposition of singlet states and sym $m$ etry breaking states:

$$
\begin{equation*}
j i=\int_{k}^{Y} \cos j S=0 ; S_{z}=0 i_{k}+\sin \text { X }(n) i_{k}: \tag{28}
\end{equation*}
$$

Here is a variable to be determ ined by the variational $m$ ethod.
A straightforw ard calculation leads to the follow ing results:

$$
\begin{align*}
\mathrm{E}(\mathrm{)} & =\mathrm{h} j \mathrm{Hji} \\
& =6 \mathrm{E}_{\mathrm{s}} \sin ^{2} \quad \text { z } \Phi_{x} \frac{2}{3}\left(\left(2^{\mathrm{p}} \overline{2} \cos \sin +\sin ^{2}\right)^{2}\right. \\
\sigma & =\left(\overline{2} \cos \sin +\frac{\sin ^{2}}{2}\right)
\end{align*}
$$

In term s of $\widetilde{Q}$, the energy can be expressed as:

$$
\mathrm{E}=6 \mathrm{E}_{\mathrm{s}} \quad \frac{4}{9}+\frac{2}{9} \widetilde{Q} \quad \frac{4}{9}^{q} \overline{2 \Omega^{2}+\hat{Q}+1} \quad \frac{8}{3} \mathrm{zJ} J_{e x} \sigma^{2}
$$

which for $\widetilde{Q} 1$ can be expanded as:

$$
\begin{equation*}
3 E_{s} \quad \frac{8}{3} z J_{e x} \quad \Omega^{2} \quad \frac{3}{2} E_{s} \Omega^{3}+\frac{39}{16} E_{s} \Omega^{4}+::: \tag{31}
\end{equation*}
$$

FIG.1: Energy ( $m$ easured in units of $E_{s}$ ) versus $\widetilde{\sim}$ for various
for $N=2$. Curves from top to bottom are for $=0: 97$, $0: 99,1: 0,1: 02$.

The cubic term leads to a rst order phase transition in the $m$ ean eld approxim ation, which is $s$ to the situation in classical nem atic liquid crystals

In FIC he Q -dependence of the energy is plotted for various In the vicinity ofa quantum criticalpoint (m ean eld). For < $0: 985$, the energy has only one $m$ in im um at $\widetilde{Q}=0$ and correspondingly the ground state is a spin singlet M ott state. W hen 0:985 \ll 1:0, in addition to the globalm inim um at $\widetilde{Q}=0$, there appears a local $m$ inim um at $\sigma>0$, which represents a spin nem atic m etastable state. $W$ hen $>1: 0$ the solution $w$ th $\widetilde{Q}>0$ becom es a globalm inim um and the solution at $\widetilde{Q}=0$ is $m$ etastable; consequently the ground state is a nem atic M ott state. For $>\frac{9}{8}$, the solution at $\widetilde{Q}=0$ becom es unstable ; but an additional local m in im um appears at $\widetilde{Q}<0$ which we interpret as a new $m$ etastable state (not show $n$ in $F I G$

The evolutionground states as is varied, is sum $m$ arized in F IG A s is clearly visible, the phase transition is a weakly rst order one. The jump in $\mathbb{Q}$ at the phase-transition ( $=1: 0$ ) is equal to $\frac{1}{2}$.

It is worth em phasising that a positive $\widetilde{Q}$ corresponds to a rod-like nem atic state; for $\widetilde{Q}=1$ the state is $m$ icroscopically given by:

$$
\begin{equation*}
\frac{\left(n^{y}{ }^{y}\right)^{2}}{\frac{2}{2}} j 0 i: \tag{32}
\end{equation*}
$$

A solution with negative $\widetilde{\sim}$ indicates a disk-like ne$m$ atic state; the $m$ icroscopic $w$ ave function is

$$
\begin{equation*}
\frac{1}{2} \text { y y } \frac{\left(n \quad{ }^{y}\right)^{2}}{2} \text { joi: } \tag{33}
\end{equation*}
$$

at $\widetilde{Q}=\frac{1}{2}$. Forn $=e_{z}$ thew ave functions are $\frac{1}{\overline{2}} \quad \frac{y}{z} \quad \frac{y}{z} j$ jii and $\frac{1}{2} \quad \underset{x}{y} \underset{x}{y}+{\underset{y}{y}}_{y}^{y}{ }_{y}^{y}$ joi respectively.

W e have also tried a ve-param eter variational approach, taking into account the fullon-site $H$ ilbert space. In a slightly di erent representation we w rite the trial

FIG. 2: The nem atic order param eter as a function of for $\mathrm{N}=2$. The phase transition takes place at $=1$. D ata along the black line represent ground states; the red line is form etastable states. Spheres w ith double-headed arrow s are introduced to represent ordering in director $n$ de ned in Eq. 25 in di erent M ott states. In spin singlet states, the director n is uncorrelated; in rod-like nem atic states, the director $n$ is ordered and in disk-like states, the axis of the easy plane of the director $n$ is ordered.
wave function as:

$$
\begin{align*}
j i= & Y\left(c_{x x} \dot{X} x i_{k}+c_{y y} \dot{y} y i_{k}+c_{z z} \dot{z} z i_{k}\right. \\
& \left.+c_{x y} \dot{X} x y i_{k}+c_{x z} \dot{X} z z i_{k}+c_{y z} \dot{y} z i_{k}\right) \tag{34}
\end{align*}
$$

Here j $i_{k}=\frac{1}{2} \stackrel{y}{k} ; \underset{k}{y}$; jOi (no sum mation) and $j \quad i_{k}=\stackrel{y}{k} \quad \underset{k}{y}$; jOi. This results in the follow ing expression for the energy:

$$
\begin{align*}
E= & E_{s} 4\left(c_{x x}^{2}+c_{y y}^{2}+c_{z z}^{2} \quad G_{x} c_{y y} \quad G_{x} c_{z z} \quad G_{y} c_{z z}\right) \\
& +6\left(c_{x y}^{2}+c_{x z}^{2}+c_{y z}^{2}\right) \\
& z \Phi_{e x} 6\left(c_{x x}^{4}+c_{y y}^{4}+c_{z z}^{4}\right)+4\left(c_{x y}^{4}+c_{x z}^{4}+c_{y z}^{4}\right) \\
& +4\left(c_{x x}^{2} c_{y y}^{2}+c_{x x}^{2} c_{z z}^{2}+c_{y y}^{2} c_{z z}^{2}\right) \\
+ & 12\left(c_{x x}^{2} c_{x y}^{2}+c_{x x}^{2} c_{x z}^{2}+c_{y y}^{2} c_{x y}^{2}+c_{y y}^{2} c_{y z}^{2}\right. \\
& \left.\quad+c_{z z}^{2} c_{x z}^{2}+c_{z z}^{2} c_{y z}^{2}\right) \\
+ & 8\left(c_{x y}^{2} c_{x z}^{2}+c_{x y}^{2} c_{y z}^{2}+c_{x z}^{2} c_{y z}^{2}\right) \\
+ & 8 \frac{2}{2}\left(c_{x x}+c_{y y}+c_{z z}\right) c_{x y}^{2} c_{x z} c_{y z} \\
& +4\left(c_{x x}^{2} c_{y z}^{2}+c_{y y}^{2} c_{x z}^{2}+c_{z z}^{2} c_{x y}^{2}\right) \\
& +8\left(c_{x x} c_{y y} c_{x y}^{2}+c_{x x} c_{z z} c_{x z}^{2}+c_{y y} c_{z z} c_{x z}^{2}\right): \tag{35}
\end{align*}
$$

$T$ he conclusions are alm ost the sam $e$ and sum $m$ arized below:
i) For $<0: 985$. the only $m$ inim um is at $c_{x x}=c_{y y}=$ $C_{z z}=\frac{1}{3}, C=0$ for $\xi$.
ii) At $=0: 985$ additional localm inim a appear.
iii) At $=1$ a rst order phase transition takes place.
iv) For $\frac{8}{9}>\quad>1$, the globalm inim $u m$ is at $\widetilde{Q}>0$, but the $\widetilde{Q}=0$-solution rem ains to be a localm inim um .
v) At $=\frac{9}{8}$ the solution at $c_{x x}=C_{y y}=c_{z z}=\frac{1}{3}$ becom es unstable.
vi) H ow ever, the disk-like $\widetilde{Q}<0$-solution appears in this case as a saddle point.

## B. A $n$ even num ber of particles per site

For a large num ber of particles per site, it is convenient to introduce the follow ing coherent state representation:

$$
\begin{equation*}
\text { jn; } i=\frac{1}{2 N_{m=N}^{N X}}{ }_{N}^{N} \exp \left(\quad i m \quad \frac{(n)^{m} y}{2(m \quad 1)!}\right. \tag{36}
\end{equation*}
$$

where the director $n$ is again a unit vector on $S^{2}$ given by (cos $\sin ; \sin \sin ; c o s$ ). In this representation

$$
\begin{align*}
\wedge & =\frac{\varrho}{\varrho} \varrho  \tag{37}\\
\hat{S} & =i n \frac{\varrho}{@ n}  \tag{38}\\
\hat{S}^{2} & =\frac{1}{\sin } \frac{\varrho}{@} \sin \frac{\varrho}{@}+\frac{1}{\sin ^{2}} \frac{@^{2}}{\varrho^{2}}  \tag{39}\\
\hat{Q} & =N \operatorname{nn} \frac{1}{3} \tag{40}
\end{align*}
$$

The Ham iltonian in Eq. 7 can be $m$ apped to a Constrained $Q$ uantum $R$ otor $M$ odel ( $C Q R$ ), describing the dynam ics of two unit vectors ( $n ; \mathrm{e}^{i}$ ) on a two-sphere and a unit circle:

$t=N E . T$ he CQR - m odel has been introduced to study spin-one bosons in a few previous w we refer to those papers for detailed discussions . For M ott states the e ective H am iltonian can be Iouna as:

$$
\begin{equation*}
H=E_{s}^{X} S_{k}^{2} \quad{\underset{\mathrm{~J}}{\mathrm{kx}}}_{\mathrm{Xk}] \mathrm{i}}^{\mathrm{X}}\left(\mathrm{n}_{\mathrm{k}} \quad \mathrm{n}^{2} ; \quad J_{\mathrm{ex}}=\frac{\mathrm{t}^{2}}{2 \mathrm{E}_{\mathrm{c}}} ;\right. \tag{42}
\end{equation*}
$$

In general, we choose the on-site trial w ave function to be:

$$
\left(n_{k}\right)=C \quad \begin{gather*}
h  \tag{43}\\
\exp \\
\frac{1}{2}\left(n_{k}\right. \\
(n)^{2}
\end{gather*}{ }^{i}:
$$

$C$ is a norm alization constant. W hen ! 0 this yields an isotropic state $Y_{00}\left(n_{k}\right)$, which indicates a spin singlet state. W hen ! +1, $n_{k}$ is localized on the tw o-sphere in the vicinity ofn $n_{0}$, representing a rod-like nem atic state and when ! $1, n_{k}$ lies in a plane penpendicular to $n_{0}$, corresponding to a disk-like spin nem atic state. $M$ oreover this $w$ ave function has the follow ing property:
$\left(n_{k}\right)=\left(n_{k}\right)$ is required for an even num ber of particles per site
$C$ hoosing $n_{0}=e_{z}$ this gives:

$$
\begin{equation*}
(k ; k)=C \exp \frac{2}{2} \cos ^{2} k \tag{44}
\end{equation*}
$$

The expectation value of the H am iltonian in this state is:
in which $\operatorname{Er}[\mathrm{X}]$ is the com plex error function de ned by $\operatorname{Erf}[\mathrm{ix}]=\mathrm{i}$. In a series expansion for 1 , the result is:

$$
\begin{equation*}
\frac{z J_{e x}}{3}+\frac{2}{15} E_{s} \quad \frac{8}{675} z J_{e x} \quad{ }^{2}+\frac{4}{315} E_{s} \quad \frac{32}{14175} z J_{e x} \quad{ }^{3}+\frac{8}{4725} E_{s}+\frac{32}{165375} z J_{e x} \quad{ }^{4}+o\left({ }^{10}\right) \tag{45}
\end{equation*}
$$

The eneron as a function of at di erent is plotin F IG which is qualitatively the sam e as F IG. for two particles per site. W hen < 9:96, the energy as a function of has only one (global) minim um, which corresponds to a spin singlet ground state. W hen
> 9:96, in addition to the globalm inim um, there appears a localm inim um at $>0$.At $=c=10: 0965$, these tw 0 m in im a becom e degenerate, signifying a phase transition. At $>c$, the solution at $=0$ becom es a localm inim um indicating a m etastable spin singlet state,

FIG. 3: Energy (in units of $\mathrm{E}_{\mathrm{s}}$ ) as a function of for various
$(\mathbb{N}=2 \mathrm{k} 1)$. From top to bottom are curves for $=9: 9$, $9: 96,10,10: 0965,10: 3$.
whereas the globalm inim um at $>0$ corresponds to a nem atic ground state. As further increases, the solution at $=0$ becom es unstable and a local minim um occurs at < 0, while the globalm inim um rem ains at
$>0$. Follow ing discussions on Eqs. 32,33 we interpret the < 0 solution as a m etastable disk-like spin nem atics.

For the trialw ave function in Eq. 45 the nem atic order param eter can be calculated as:

$$
\begin{align*}
\widetilde{Q} & =\frac{h \hat{Q} \hat{j} i}{h \mathcal{1} \hat{Q} \hat{\mathcal{H}} i} \\
& =\frac{1}{2} \frac{3}{4}+\frac{3 e}{2} \frac{3 e}{j E r} \bar{j} j \tag{46}
\end{align*}
$$

$W$ hen $\mathbb{Q}$ is sm all, we obtain an expression of the energy in term sof $\mathbb{Q}$ :
$E_{Q^{\Upsilon}}=\frac{z J_{e x}}{3}+\frac{15}{2} E_{s} \quad \frac{2}{3} z J_{e x} \quad \Omega^{2} \quad \frac{75}{14} E_{s} \Omega^{3}+\frac{1275}{98} E_{s} \Omega^{4}$

The jum p in $\mathbb{Q}$ at the phase transition is equalto :323377.
$T$ he evolution of ground state wave functions and results on quantum phase transitions are sum $m$ arized in
gur where the nem atic order param eter is plotted as a function of .
C. A $n$ odd num ber of particles per site

At last, we also present results for an odd num ber of atom $s$ per site. The $m$ ain di erence between this case and the case for an even number of particles per site is that at zero hopping lim it in the form er case there is alw ays an unpaired atom at each site. C onsequently in the $m$ ean eld approxim ation, we only nd nem atic M ott insulating phases. $W$ e expect this approxim ation

FIG.4: N em atic order param eter as a function of for $\mathrm{N}=$ 2k (1). A long the black lines are ground states; along the red lines are $m$ etastable states. (See also the caption of F IG . 2.)
to be valid in high dim ensional lattioes but to fail in low dim ensions, especially in one-dim ensional lattioes where long wave length uctuations are substantial. Here we restrict ourselves to high dim ensional lattioes only.

For large $N$ a trialw ave function which intenpolates betw een spin singlet states (dim erized) and nem atic states can be introduced as:

$$
\left.\begin{array}{rl}
\text { odd }\left(f n_{k} g\right)= & Y \\
h_{k} l_{\mathrm{p}} \\
& C(O ;)\left(O ( \begin{array} { l l l } 
{ n _ { k } } & { \cap }
\end{array} ) \left(n_{1} \quad \emptyset\right.\right. \tag{48}
\end{array}\right)+\left(n_{k}\right)
$$

$h k i_{i}$ denotes that the sum $m$ ation should be taken over parallely ordered pairs of nearest neighbours $k$ and lcovering the lattice. $\mathrm{C}(\mathrm{O} ;)$ is a norm alization constant. T he solution w th $\mathrm{O}=0$; $=0$ corresponds to a dim erized valence bond crystalstate; and solutionsw ith $O \in 0$, or $\in 0$ represent nem atic states.

It is straightforw ard, but tedious to com pute the energy of these states. $M$ inim izing it for variouls va hies of
for $d=3$ gives the results show $n$ in F IG and $U P$ to $=1$ no phase transitions are found in the $m$ ean eld approxim ation; and ground sin break both rotational and translational sym m etries
At very sm all , the on-site H ilbert, e is truncated into the one for a spin-one partic- The reduced H am ittonian in the truncated space is a B ilinear$B$ iquadratic $m$ odel for spin-1 lattioes

$$
\begin{align*}
& \mathrm{H}_{\mathrm{b}: \mathrm{b}}=\mathrm{J}_{<\mathrm{k} \downarrow>}^{\mathrm{X}}\left[\begin{array}{lllll}
\cos & \mathrm{S}_{\mathrm{k}} & \mathrm{~S}+\sin & \left(\mathrm{S}_{\mathrm{k}}\right. & \mathrm{S}^{2}
\end{array}\right] ; \mathrm{S}_{\mathrm{k}}^{2}=2 ;(49)  \tag{49}\\
& \text { in general varies betw een } 3=4 \text { and } \quad=2 . \mathrm{W} \text { e there- }
\end{align*}
$$ for expect ground states at sm all lim it should still exhibit nem atic order (i.e. $O$ ) .

It is worth em phasizing that conclusions about sm all
lim it arrived here are only valid in high dim ensional

bipartite lattioes. In low dim ensional lattices, states of correlated atom s in this lim it w as discussed recently and ground states could potationally invariant dim erized-valence-bond crysta

## IV . CONCLUSIONS

W e have studied them icroscop ic $w$ ave functions of sp in nem atic and spin singlet $M$ ott states. B oth disk-like and rod-like spin nem atic states were investigated. W e also have analysed quantum phase transitions between the spin singlet $M$ ott insulating state and the nem atic $M$ ott insulating state. W e show that in the m ean eld approxi$m$ ation, the phase transitions are weakly rst order ones. Thus, we expect that uctuations play a very im portant role in these transitions and the fill theory on quantum phase transitions rem ains to be discovered.

On the other hand, we have estim ated uctuations in di erent regim es of the param eter space. $W$ e found that uctuations are indeed sm allaw ay from the criticalpoint, at either sm allhopping or large hopping lim it for an even num ber of particles per site. For the sm all hopping lim it, uctuations are proportional to , while for large hopping lim it they can be estim ated as being proportional to $\frac{1}{1}$.

For an odd num ber of particles per site, uctuations are sm all only at large hopping lim it and are signi cant at sm all hopping lim it. T he later fact implies a large degeneracy of $M$ ott states at zero hopping lim it which was em phasised in the discussions on low dim ensional $M$ ott states. T he physics in this lim it rem ains to be fully understood.

In the context of antife spin nem atic states have also been proposed Collective excitations in atom ic nem atic states snoura be studied in previous works and we refer to for details.

## V.ACKNOW LEDGEMENT

This work is supported by the foundation $F O M$, in the N etherlands under contract 00C C SP P 10m 02SIC 25 and NW O M K projectruim te 00P R 1929; M S is also partially supported by a grant from U trecht U niversity.

N ote added: At a later stage of this work, we received a copy of the $m$ anuscript by A. Im am bekov, M. Lukin and E. D em ler where sim ilar conclusions have been arrived.

> APPENDIX A:ANALTERNATIVE DESCRIPTION

A ltematively, one can also carry out the calculations in section III, using the follow ing operator:

$$
\begin{align*}
& \hat{Q}_{2 ;} \quad=\hat{S} \hat{S}^{0} \frac{1}{3} \quad 0 \hat{S} \hat{S} \\
&=000 \quad \mathrm{y} \mathrm{y}_{0} \quad 0+\quad 0 \mathrm{y}  \tag{A1}\\
& \mathrm{y}_{0} \quad \frac{1}{3} \quad 0 \hat{S}_{\text {tot }}^{2}
\end{align*}
$$

De ning the $m$ ore conventional order param eter

$$
\begin{equation*}
\widetilde{Q}_{2}=\frac{\hat{\mathrm{Q}}_{2} ; \quad \hat{i}^{\mathrm{i}}}{\mathrm{~h} \hat{Q}_{2 ;} ;} ; \tag{A2}
\end{equation*}
$$

we obtain the follow ing results for the trial w avefiunction in Eq. 28:

$$
\begin{aligned}
& \widetilde{Q}_{2}={ }^{r} \frac{3}{2} \sin ^{2} \\
& E=6 E_{s} \frac{\frac{2}{3} \sigma_{2}}{0}
\end{aligned}
$$

$$
\begin{aligned}
& =2^{p} \bar{\sigma} \mathrm{E}_{\mathrm{s}} \frac{16^{r}}{3} \frac{-2}{3} z J_{e x} \quad \widetilde{\Omega}_{2} \\
& \frac{16^{p_{4}} \overline{2}}{\mathbb{P}_{4}} z^{3^{7}} J_{e x} \mathscr{Q}_{2}^{3=2}+\frac{28}{9} z J_{e x} \widetilde{Q}_{2}^{2}+O\left(\widetilde{Q}_{2}^{5=2}\right)
\end{aligned}
$$

which lead to the sam e conclusions as in section III. H ow ever, in term s of the order param eter de ned in Eq. A 2, the rod-like and disk-like structures shown in FIG 2 and F IG . 4 are less obvious.

In the case of a large num ber of particle per site, the order param eter introduced here has the sam e expectation value as the operator in Eq. 40.
