# On the phase of oscillatory $m$ icrow ave photoresistance and zero-resistance states 

M . A. Zudov<br>D epartm ent of Physics, U niversity of $U$ tah, Salt Lake C ity, $U$ tah 84112<br>(R eceived 19 June 2003)

#### Abstract

W e present phenom enological analysis of the period, and the phase of oscillatory $m$ icrow ave pho-  $T$ he results dem onstrate that as OMP evolves into ZRS w ith increasing magnetic eld, the absolute value of the phase becom es progressively sm aller, decreasing roughly as $1=\mathrm{B} . \mathrm{V}$ irtually elim inating a phase-shift and resulting in di erent periodicities for the $m$ axim $a$ and $m$ in $\dot{m} a$, such speci $c$ dependence is supported by a sim ple m odel based on oscillatory density of states. F inally, it follow $s$ that ne structures rst reported in $R$ ef. 3 can be view ed as an experim ental evidence for m ulti-photon processes.

PACS num bers: $73.40 .-\mathrm{c}, 73.43 .-\mathrm{f}, 73.21 . \mathrm{b}$
$U \sin g$ innovative $m$ icrow ave ( $M$ W ) photoconductivity spectroscopy of 2D electron system $s$ (2DES) originally em ployed in experim ents on oscillatory $m$ icrow ave photoresistance (OMP) $)^{11}$, two research groups have recently reported on a series of \zero-resistance states" (ZRS) ${ }^{2 / 31}$ em erging from the OMP minim a in ultra-high quality samples. $M$ anifesting a novel dissipationless regim $e$, such states appear when the $M W$ frequency, $!=2 \mathrm{f}$, som ew hat exceeds the cyclotron frequency, $!_{c}=e B=m$, of the 2DES ( $m$ is the e ective electron m ass) and are characterized by an exponentially sm all low tem perature resistance and a classical Hall resistance. M ore recently, experim ents have been extended to probe dc conductivity in C orbino rings of 2D E S revealing \zero-conductance states" (ZCS) ${ }^{11_{1}^{\prime}}$ in agree$m$ ent $w$ ith standard de $m$ agneto-transport tensor rela-
 ical interest 5 and hasbeen con m ed in independent experim ents 10.1 As it was realized that even the m echanism of the originalOM P lacks understanding, the rst step forw ard was $m$ ade by Durst et ${ }^{-15_{1}}$ who related the phenom enon to radiation-induced im purity-assisted scattering (in- fact, sim ilar ideas w ere proposed decades ago by R yzhin 12 ). R egardless of the microscopic nature of the OM P, it was established experim entally ${ }^{291}$ that the sam plem obility favors OM P am plitude at the sam e tim e reducing background resistance. Therefore, one could intuitively expect that further im proving sam ple quality w ould eventually lead to zero or even negative resistance at the OMP minim $a_{r_{r}} A_{\text {a }}$ s the later scenario is not experim entally realized 2 , 2 , 4 A ndreev et al presented strong argu$m$ ents show ing that a negative resistance (conductance) state, regardless of its origin, is intrinsically unstable. $T h i s$ instability $y_{1}$, leads to form ation of current (electric
eld) dom ainsill 1 there are no new experim ents available to date to test these or other theories, current understanding of the phenom enon appears far from com plete. Furthem ore, while there seem $s$ to be a consensus about the period of the $Z R S$, the value of the, phase seem $s$ to be controversial, even experim entally 4

OM P (ZRS) m odels seem to account for, and som e [see, e.g. Ref. 2] even rely on a speci c value of the phase, we feel that it would be usefiul to address the origin of this discrepancy.

In this paper we present detailed analysis of the period and the phase of the OMP/ZRS,whidh,w e hope, com ple$m$ ents original experim ental ndings 213 l The results indicate that evolution of the OM P into ZRS w ith increasing $m$ agnetic eld is accom panied by a dram atic reduction of the phase. W e nd that in the ZRS regim e the phase decreases roughly as $1=B$ and such dependence virtually elim inates a \1=4-cycle" phase shift attributed to ZR S by the authors of $R$ ef. 2. W hile a speci c origin of such a dependence is not clear at this point, we show that, under reasonable assum ptions, it is consistent $w$ ith an ideal that M W photoresistance roughly follow s the derivative of the density of states (D OS ). Finally, we show that ne structures rst reported in Ref. 3 can be view ed as an experim ental evidence form ulti-photon processes.

O ne of the puzzles surrounding experim ental reports is that, despite a great deal of sim ilarity between the data presented in Ref. 2 and that of Ref. 3, conclusions regarding the phase of the $Z R S$ w ere quite di erent. $M$ ani et ad have found the positions of them axim $\mathrm{a} / \mathrm{m}$ inim a (, respectively) of both the OMP and $Z R S$ to be described by:

$$
\begin{equation*}
"_{j}=j \quad 1=4 \tag{1}
\end{equation*}
$$

where " $\quad!=!_{C}$ and $j$ is a positive integer. A ccording to Eq. (1) m axim a (m inim a) appear blue (red)-shifted by a $\backslash 1=4$-cycle" from the cyclotron resonance harm onics, $"_{j}=j$, and the $m$ agnetoresistance can be viewed as a single-harm onic function w ith the phase, $=0.25$.

On the other hand, Zudov et al have reported that
 As far as the $m$ ajor $m$ inim a are concemed, their positions, contrary to the $m$ axim a, are not well de ned since ZRS span a w ide range of the m agnetic eld. N aively one could take the ZR_S center as its position but the higher tem perature, data ${ }^{3}$ and apparent asym $m$ etry of the $m$ ajor $m$ axim al rule against such single-harm onic picture. Therefore, Zudov et a-1 have proposed that ZRS could
also be view ed as a roughly periodic (in 1=B ) sequence, w ith no apparent phase shift, although $w$ ith a som ew hat enhanced periodicity [cf., Fig. 3 in Ref. 3]. H ere we sum $m$ arize the observations of $R$ ef. 3 as follow $s$ :

$$
\begin{equation*}
"_{j}=j ; j<4 \tag{2}
\end{equation*}
$$

where is a constant close to unity. H igher-order ( $j>4$ ) OMP were found to conform to Eq. (1) although such approach required a som ew hat reduced value of the e ective mass ( $\mathrm{m}_{10}=0: 064 \mathrm{~m}_{0}$ ), as opposed to $m_{h i}=0: 068$ obtained using Eq. (2) for $j<4$ 3al

It immediately follows that, experimentally, the boundary of applicability of Eqs. ([1]) and $\left.\overline{[\Omega}_{1}^{-1}\right)$,i.e., j 4,

F IG .1: (a) Solid (open) circles are experim ental values of the phase, $="_{j} \quad j$, extracted from the datalis (inset) taken at $T=0.9 K(T=2.7 K)$ and $f=57 \mathrm{GHz}$. Solid lines: calculated using Eq. $\left(d_{1}\right)$ form $=0: 064$ and $=0: 3 \mathrm{~K} . \mathrm{D}$ ashed lines are asym ptotes of Eq. $\left(\bar{T}_{1}\right)$ calculated using the sam e param eters. (b) M agnetoresistance under M W ilhum ination of $f=$ 57 GHz taken at $\mathrm{T}=0.9 \mathrm{~K}$ (also seen in the inset ofF ig. 1 (a)) plotted as a function of ". Vertical lines are calculated using

seem $s$ to also separate the regim es of the OMP from that of the ZRS; being described by di erent equations MW photoresistance for $j>4$ corresponds to the OMP regim e, while ZRS appear at $j<4$. To reconcile Eqs. (1) and (2) we propose the follow ing expression

$$
\begin{equation*}
"_{j}=j+\quad ; \tag{3}
\end{equation*}
$$

where is now allowed to vary w ith ", approaching
0.25 as " increases. In what follow s , we analyse the phase, ${ }_{1-} \quad "_{j} \quad j$, extracted from our experim ental data ${ }^{131} 1311$ as a function of " 123

In $F$ ig. 1 (a) we present the experim ental value of the phase, , extracted from m agnetoresistance traces ${ }^{31}$ (see inset) taken at $\mathrm{T}=0.9 \mathrm{~K}$ (solid circles) and $\mathrm{T}=2.7$ K (open circles) for $f=57 \mathrm{GHz}$. H orizontal dashed lines $m$ ark a \1/4-cycle" phase-shiff, which is readily observed in experim ent for both $m$ axim a and $m$ inim a at " $>4$. At $"<4$, positions of the $m$ inim a at low tem perature cannot be accurately determ ined and we lim it our discussion to the m axim a positions (as discussed later in the text, $m$ inim a positions are expected to follow sim ilar dependence). W ith decreasing " we observe a dram atic reduction of $j^{+} j$ roughly linearw ith ", ie., ${ }^{+} \quad{ }^{+}$", w th $+6: 4 \quad 10^{2} \quad$ 1. We im m sodiately note that, in agreem ent w th earlier conclusions, ${ }^{311}$ such a dependence does not produce any phase-shift but a ects periodicity [cf., E q. (2) ]. Indeed, substituting this result into Eq. (ǐ3) one obtains $\mathbf{~ " ~}^{+}=j=\left(1+{ }^{+}\right) \quad\left(1 \quad{ }^{+}\right) j$ which is just Eq. (2). W e can now relate the phenom enologicalparam eter ${ }^{+}$to the-di erence betw een the e ective $m$ asses extracted earlier ${ }^{301}$ from them axim a positions using Eq. (1) for $j^{>} 4\left(m_{10}=0: 064\right)$ and Eq. (2) (w ith ${ }^{+}=1$ ) for $j<4\left(\mathrm{~m}_{\mathrm{hi}}=0: 068\right)$. We note that com pletely ignoring the phase-shiff results in an overestim ation of the $m$ ass by approxim ately ${ }^{+} \%$, consistent $w$ th the data of F ig. 1 (a). W hile the m inim a positions at " < 4 could be accessed at elevated tem peratures, e.g. $\mathrm{T}=2.7 \mathrm{~K}$, the extracted phase (open circles) does not seem to follow such a simple linear dependence on ". W hile the sam $e$ is true for the $m$ axim a at this $T$, the origin of such enhancem ent of the phase rem ains unclear.

It is interesting to exam ine the extracted phase in term sof the recent theoreticalproposals. H ere we chose a \toy m odel" proposed by D urst et aFl who suggested that M W photoresistance roughly follow s the derivative of the D oS taken at $\mathrm{E}=\mathrm{h}$ !. The condition describing the positions of the $m$ axim $a$ and $m$ inima in the OMP (ZRS) structure is then given by:

$$
\begin{equation*}
{\frac{d^{2} N(E)}{d E^{2}}}_{E=h!}=0 \tag{4}
\end{equation*}
$$

U sing a well-known fact that in weak $m$ agnetic eld the oscillatory part of the D oS behaves as $\cos \left(2 \mathrm{E}=\mathrm{h}!{ }_{c}\right)$, Eq. (1) is easily recovered. It is well know n, how ever, that $w$ ith increasing $m$ agnetic eld, cyclotron energy will eventually exceed the Landau level (LL) w idth and D oS w illno longerbe described by a single-harm onic function.

D ue to this，in regular $m$ agnetotransport，Shubnikov－ de Haas（SdH）e ect evolves into a quantum Halle ect （ QHE ）w ith increasing m agnetic eld（or sam ple $m$ obil－ ity）．Intuitively，one could think that sim ilar m agnetic－ eld－driven transition $m$ ight，be responsible for the evolu－ tion of the OM P ${ }^{1_{1}^{1}}$ into ZRS S ${ }^{n_{1}^{1 / 32}} Q$ ualitatively it is straight－ forw ard to see that as the D oS deviates from a sinusoidal form w ith increasing $m$ agnetic eld，the phase w illbe re－ duced rendering Eq．（1）invalid and therefore irrelevant to the ZRS regim e ．

For quantitative com parison w ith experim ent we as－ sum e that LLs have Lorentzian shape characterized by a eld－independent width， 133 Then the D oS can be w rit－ ten as：

$$
\begin{equation*}
N(E)={\frac{1}{2}{\underset{0}{n}}_{\mathrm{n}}^{\mathrm{X}} \frac{}{\left(E \quad \mathrm{nh}!_{\mathrm{C}}\right)^{2}+{ }^{2}} ; ~ ; ~}_{\text {; }} \text {; } \tag{5}
\end{equation*}
$$

$w$ here $n$ denotes the $L L$ index and ${ }_{0}=P \overline{h=e B}$ is the $m$ agnetic length．E xperim entally we are constrained to the case of very high LLs（ $h$ ！$E_{F}, E_{F}$ is the Ferm i energy），therefore，the sum $m$ ation can be taken over in－ nite lim its yielding analytical solution．A fter introduc－ ing dim ensionless units $("=E=h!c r==h!c$ ，and $\left.\mathrm{n}(\mathrm{\prime})=\mathrm{N}(\mathrm{E}) \mathrm{h}!_{\mathrm{c}} \quad{ }_{0}^{2}\right)$ ，one obtains：

$$
\begin{equation*}
\mathrm{n}(")=\cos ^{2}(\text { " }) \tanh (\quad)+\sin ^{2}(\text { " }) \operatorname{coth}(\quad) \tag{6}
\end{equation*}
$$

 ing for＂one obtains Eq．（ $\overline{-3})$ w ith the phase of the form：
$=\frac{1}{2} \arccos$
where $=1=2 \quad y+p \frac{y^{2} \quad y+9=4}{y^{2} y=\cosh ^{2}(\quad),}$
and is the phase for the series of maxim a／m inim a， and is the phase for the series of $m$ axim $a / m$ in $m a$ ， respectively．

At lowerm agnetic elds（ 1），y 1，$\quad y^{1} \quad 1$ ， so $\quad 1=4$ and Eqs．${ }_{1}^{(1)(7)}$ reduce to Eq．（1）． O ne can also arrive at the sam e conclusion by notic－ ing that in this lim it，as mentioned earlier，the DoS becom es a single－harm onic function of＂，i．e．，$n(")=$ $1+2 \exp (2) \cos (2$＂）．
$M$ ore interesting results em erge at higher magnetic elds（ 1），when LLs becom e well separated．In this lim 五，$y \quad p^{1}+2^{2}=2, \quad 1+2^{2}{ }^{2}=3$ ，which leads to $\quad=\overline{3}$ ．O ne can also easily obtain the sam e result by considering an isolated Lorentzian line．W e im－ $m$ ediately note that the phase is decreasing as $1=B$ ，in agreem ent w ith experim ental data plotted in $F$ ig． 1 （a）， leading to j／1＝B［cf．，Eq．（2）］：

$$
\begin{equation*}
j=\frac{h!\quad \stackrel{p}{=} \overline{3}}{h!_{c}}: \tag{8}
\end{equation*}
$$

A few comments are appropriate．First，Eq．（便）is consistent $w$ ith our experim entalobservation ${ }^{131}$ regarding the positions of the $m$ a jor $m$ axim a and $m$ inim a．O scilla－ tion order $j$ for the $m$ axim $a$ and $m$ inim a scales linearly
w ith＂，w ith no apparent phase，but w th di erent pref－ actors［cf．，in Eq．（2）］；it is easy to see that since

1，1，as observed experim entally．Second，the asym $m$ etry of the ZRS portion of the $m$ agnetoresistance trace can now be understood，since Eq．（⿳亠口冋口1）dictates oscil－ lations to appear as closely－spaced $m$ axim um $-m$ inim um pairs，centered about integer values of＂＝j．Third，since experim entally OMP（ $j>4$ ）and ZRS（ $j<4$ ）conform to di erent resonant conditions（Eq．（1）and Eq．（2），re－ spectively）this $m$ odel suggests that ZRS develop from the OMP minim a as a result of a magnetic－eld－driven transition taking place around $h!{ }_{c}=2$ 1．Such a tran－ sition would roughly occur when $=\quad=\overline{3}$ reaches its low－eld $\lim$ it of $1 / 4$ ．Indeed，it happens when $h!{ }_{c}=2={ }^{\mathrm{P}} \overline{3}=2 \quad$ 1． F inally，it is interesting to m en－ tion that Eq．（G）provides a direct experim entalm ethod to probe，which is not directly accessible in standard $m$ agnetotransport，both in SdH（1）and in Q HE （ 1）regin e．$W$ e also $m$ ention that $m$ ore detailed m icroscopic calculations $w$ thin a self－consistent Bom approxim ation ${ }^{2 \cdot 2}$ predict sim ilar reduction of the phase $w$ ith increasing $m$ agnetic eld．

U sing Eq．$\left.(\bar{q})^{\prime}\right)$ we can now relate the phenom enolog－ ical param eter to ，i．e．，$=\overline{3} \mathrm{~h}$ ！ 0.3 K （ h ！ $2: 7 \mathrm{~K}$ ，as expected）．We can also roughly estim ate the num ber of developed ZRS，as h！＝（2）4，
 com pute the $m$ axim a positions for the whole range of＂ for com parison w ith experim entaldata ${ }^{3}$ In Fig .1 （b）we present the results of such calculations shown by verti－ cal lines along w th experim ental trace for $f=57 \mathrm{GHz}$ adopted from Ref．3，but now＿replotted as a function of ＂．W hile it was show $n$ before ${ }^{30}$ that Eq．（1）works well only for＂$>4$ and Eq．（2）for $"<4$ ，Eqs．（ $(\underline{3}),(\overline{7})$ pro－ vide excellent agreem ent over the whole range of＂，both in OMP and ZRS regim es．In Fig． 1 （a）we now present ，calculated using Eq．（ $\bar{T}_{1}$ ）for $\mathrm{m}=0: 064$ and $=0: 3$ K（solid lines），and again observe good agreem ent w ith low tem perature experim entaldata ${ }^{3_{1}} \mathrm{D}$ ashed lines cross－
 perim entally，we observe that this crossing point roughly $m$ arks a transition from OMP to ZRS［cf．Fig． 1 （b）］．An enhancem ent of the phase at higher $T$ can now be related to the therm albroadening of LLs．

O nce we have established that OMP can be view ed as $m$ axim um $m$ inim um pairs associated $w$ ith integer $j$ and positioned around＂＝j，we can try to generalize Eq．（Zָi） for the processes involving multiple photons．W hile it seem s unlikely that such higher－order processes w ould be readily resolved experim entally，our data ${ }^{13}$ suggest that such a scenario deserve close exam ination，especially in light of recent theoreticalcom $m$ ents $51,1,1,34$ ．For the case of $m$－photon processes and 1 ，the $m$ axim um $-m$ inim um pairs are to appear roughly sym $m$ etrically around frac－ tional＂and the expression（ $\underline{l}^{1}$ ）ism odi ed as follow s（here

F IG . 2: M agnetoresistance under M W illum ination of frequency (a) 57 GHz and (b) 31.5 GHz . Vertical lines are draw n at $"=j=m=3 / 2,5 / 2$ (a) and $1 / 2,2 / 3$ (b). Vertical arrow $s$, placed sym $m$ etrically about $j=m \quad m$ ark $m$ axim um $m$ inim um pairs at ${ }_{j m}=j=m \quad j m$.
we do not attem pt to calculate jm ):

$$
\begin{equation*}
"_{j m}=\frac{j}{m} \quad j m \tag{9}
\end{equation*}
$$

where $m=2 ; 3 ; 4:::$. For instance, two-photon processes ( $m=2$ ) would reveal them selves as a series of $m$ axim um m inim um pairs close to half-integer values of ", e.g. $1 / 2,3 / 2,5 / 2, \ldots$. To prove the feasibility of such
scenario, we present in F ig. datal taken under illum ination w th $\mathrm{M} W$ radiation of $\mathrm{f}=57 \mathrm{GHz}$ but now plotted over the narrow range of ". $M$ axim um m inim um pair centered at " $=3=2$ and m arked by vertical arrow s is clearly observed and sim ilar structure seem s to develop around " = 5=2. W hile such secondary peaks appearing at " > 1 m ay be possibly explained by other $m$ echanism $s$, structures em erging at " < 1 present stronger support for $m$ ulti-photon transitions as these naturally allow to enter the region of " < 1. In Fig. for $f=31: 5 \mathrm{GHz}$ and focus on the region of " $<1$. The structure centered around " = 1=2 is com parable in am plitude to the prim ary single-photon structure around " $=1 . \mathrm{W}$ e notice that this feature is best observed at low M W frequencies ${ }^{3}$ and quickly disappears at $\mathrm{f}>40$ G H z as it gradually shifts into SdH regim e. In addition, there appears yet anotherm axim um m inim um pair close to " = 2=3 which w ould suggest an even less-likely, threephoton process. B ased on the good agreem ent of the positions, we believe that secondary peaks rst observed in Ref. 3 are due to multi-photon processes as described by Eq. $(\underline{1})$ ) for $m=2$. $T$ he test for such a conclusion would be the system atic pow er-dependence experim ents which are deferred for future studies.

In sum $m$ ary, we have studied the period and the phase of the MW photoresistanc over the wide range of ", covering both $O M P$ and $Z R S$ regim es. A s OMP evolves into ZRS w ith increasing magnetic eld we observe a dra$m$ atic reduction of the phase, which decreases roughly as 1=B. Such a decrease results in di erent periodicities for the $m$ axim a and $m$ inim $a$, but both exhibit no apparent phase-shift, in agreem ent with our earlier report ${ }^{13}$ A ssum ing that, M W photoresistance follow s the derivative of the DOS ${ }_{5}^{15}$ ZRS and OMP can be viewed as two different experim ental regim es separated by the condition $h!{ }_{c}=2 \quad$ 1. D espite obvious oversim pli cation, such an intuitive $m$ odel seem $s$ to capture the behavior of the ZRS position/phase quite well but we do not rule out other explanations. Finally, we identify additional structures rst reported in Ref. 3 as resulting from multi-photon processes taking place around fractional values of ", e.g. " 1=2;3=2;:::

W e would like to thank R.R.D u, V.A.A palkov, and M. G.Vavilov for reading the $m$ anuscript and valuable rem arks. This work is supported by DARPA.

For additional sam ple param eters and experim ental details the reader is referred to Ref . 3.
32 Here, we chose $\mathrm{m}=0: 064 \mathrm{~m} 0$ deduced from the OMP regim e because it encom passes, experim entally, a much w ider range of " as com pared to the ZRS regim e. W e notice an apparent discrepancy between the deduced $m=$ $0: 064 \mathrm{~m} 0$ and the generally accepted value of $0: 068 \mathrm{~m} 0$ for GaAs. The di erence ( 6\%) well exceeds experim ental uncertainties.
${ }^{33} \mathrm{~W}$ hile a choice of a lineshape of the LLs (e.g., gaussian or Lorentzian) is not particularly im portant for our discussion, we notice that the assum ption regarding the $B-$ independent width of the LL contradicts to the generaly accepted $\bar{B}$-dependence obtained using pa self-consitent B om approxim ation, which w ould lead to a "-dependence of the phase, .W hether high-tem perature data presented in $F$ ig. 1 (b) indicate such dependence rem ains to be clari ed by future experim ents. W e also note that our choice w as successfully used in SdH form alism.
