# Scattering length for com posite bosons in the BCS-BEC crossover 

P.P ieriand G .C. Strinati<br>D ipartim ento diF isica, U dR IN FM, U niversita di C am erino, I-62032 C am erino, Italy

#### Abstract

$T$ he present $m$ anuscript concems the calculation of the boson-boson scattering length for the com posite bosons that form as bound-ferm ion pairs in the strong-coupling lim it of the BCSBEC crossover. The $m$ aterial presented in this $m$ anuscript was already published as a part of a longer paper on the BCSBEC crossover problem (P.P ieri and G.C.Strinati, Phys. Rev. B 61, 15370 (2000)). G iven the recent experim ental advances on the form ation of ultracold bosonic $m$ olecules from a Ferm i gas of atom s by a Feshbach resonance, the calculation of the boson-boson scattering length has now becom e of particular interest. The present short version of the above paper could thus be helpful to the scienti c com munity working on ultracold atom ic gases. A ccordingly, the present $m$ anuscript is intended for circulation as a preprint only.

The recent form ation of ultracold bosonic $m$ olecules from a Ferm igas of atom ${ }^{\text {S }}$ by a Feshbach resonance allow sfor an experim ental check of theoretical calculations forphysicalquantitiesw th in the BCSBEC crossover. In particular, in Ref . boson scattering length $a_{B}$ and the ferm ionic scattering length $a_{F}$ was calculated in the strong-coupling lim it of the BCSBEC crossover. The summ ation therein of all bosonic $T$-m atrix diagram $s$ has led to the result $a_{B}=0: 75 \mathrm{a}_{\mathrm{F}}$. This result corrects the value $\mathrm{a}_{\mathrm{B}}=2 \mathrm{a}_{\mathrm{F}}$ obtained w ithin the B om approxim ation for the e ective residualbosonic interaction ${ }^{3}\left\{15151\right.$. The result $a_{B}=0: 75 a_{F}$ could be tested experim entally in the near future, by $m$ easuring at the sam $e$ tim $e$ the $m$ olecule-m olecule scattering length and the ferm ion-ferm ion scattering length while scanning the $m$ agnetic eld through the Feshbach resonance.

In this $m$ anuscript, we provide a condensed version of the $m$ aterial published in Ref. $\overline{1}, \mathbf{l}$, focusing speci cally on the calculation of the bosonic scattering length. W e hope that this short sum $m$ ary of our previous work could be useful to the scienti $c$ com $m$ unily at the present tim $e$.
I. BUILD $\mathbb{N}$ G BLOCKS OF THE

DIAGRAMMATIC STRUCTUREFOR COMPOSITEBOSONS

In this section, we discuss the diagram $m$ atic structure that describes generically the com posite bosons in term s of the constituent ferm ions. O ur theory rests on a judicious choice of the ferm ionic interaction, which (w ithout loss of generality) greatly reduces the num ber and considerably simpli es the expressions of the Feynm an diagram $s$ to be taken into account.

## A. R egularization of the ferm ion ic interaction

W e begin by considering the follow ing H am iltonian for interacting ferm ions (we set $P$ lanck $h$ and Boltzm ann $k_{B}$ constants equal to unity throughout):

$$
\begin{align*}
& H=X^{Z} d r y_{(r)} \frac{r^{2}}{2 m} \\
& +\frac{1}{2} X^{Z} Z_{0} d r d r^{0}(r)^{Y_{0}\left(r^{0}\right) V_{e}}(r \quad r) \quad 0\left(r^{0}\right) \tag{r}
\end{align*}
$$

Here, (r) is the ferm ionic eld operatorw ith spin projection $=(" ; \#), m$ the ferm ionic $m$ ass, the ferm ionic chem icalpotential, and $V_{e}\left(\begin{array}{ll}r & l\end{array}\right)$ the e ective potential that provides the attraction betw een ferm ions. For the application to atom ic gases, the two spin states correspond to two di erent hyper ne states of the ferm ionic atom s .

To simplify the ensuing $m$ any-body diagram matic structure (yet preserving the physicale ects we are af, ter), we adopt for $V_{e}$ the form of a \contact" potential ${ }^{6}$

$$
V_{e}\left(\begin{array}{ll}
r & l
\end{array}\right)=V_{0} \quad\left(\begin{array}{ll}
r & f \tag{12}
\end{array}\right)
$$

$w$ here $v_{0}$ is a negative constant. $W$ ith this choice, the interaction a ects only ferm ionsw th opposite spins in the H am iltonian (1.1) ow ing to P auli principle. A suitable regularization of the potential $\left(1 \begin{array}{l}1 \\ 1\end{array}\right)$ is, how ever, required to get accurate control of the $m$ any-body diagram $m$ atic structure. In particular, the equation (in the center-ofm ass fram e)

$$
\begin{equation*}
\frac{\mathrm{m}}{4 \mathrm{a}_{\mathrm{F}}}=\frac{1}{\mathrm{v}_{0}}+\frac{\mathrm{Z}}{(2)^{3}} \frac{\mathrm{dk}}{\mathrm{k}^{2}} \tag{1,3}
\end{equation*}
$$

for the ferm ionic scattering length $a_{F}$ associated $w$ ith the potential ( 1 the three-dim ensional w ave vector $k$ is ultraviolet divergent. $T$ he delta-function potential (12) is then regularized, by introducing an ultraviolet cuto $\mathrm{k}_{0}$ in the integralofEq. (1.3) and letting $\mathrm{v}_{0}$ ! 0 as $\mathrm{k}_{0}$ ! 1 , in order to keep $a_{F}$ xed at a nite value. The required relation between $\mathrm{v}_{0}$ and $\mathrm{k}_{0}$ is obtained directly from Eq. ( 1 O ne nds:

$$
\begin{equation*}
\mathrm{v}_{0}=\frac{2^{2}}{\mathrm{mk}_{0}} \quad \frac{3}{\mathrm{ma}_{\mathrm{F}} \mathrm{k}_{0}^{2}} \tag{1.4}
\end{equation*}
$$

when $\mathrm{k}_{0} \dot{\text { ja }}_{\mathrm{F}} \mathrm{j} 1$.
W ith the regularization $\left(\frac{1}{1}, \overline{4}\right)$ for the potential, the classi cation of the $m$ any body diagram $s$ gets considerably
sim pli ed, since only speci c sub-structures of these diagram s survive when the $\lim$ it $\mathrm{k}_{0}$ ! 1 is eventually taken. In particular, in order to obtain a nite result for a given Feynm an diagram, the vanishing strength $\mathrm{v}_{0}$ of the potential should be com pensated by an ultraviolet divergence in som e intemalw ave-vector integration. For the particle-particle ladder of $F$ ig. ${ }_{\underline{1}}^{1} \overline{1} 1$, the intemal w avevector integration associated w ith each rung diverges in the $\lim$ it $k_{0}!1$ and com pensates the vanishing of $v_{0}$, yielding the nite result:

$$
\begin{aligned}
& 0(q)=\frac{m}{4 a_{F}}+\frac{\mathrm{dk}}{(2)^{3}} \\
& \frac{\tanh (\quad(k)=2)+\tanh \left(\begin{array}{lll}
(k & q)=2) \\
2( & (k)+(k \quad q) & i)
\end{array} \frac{m}{k^{2}} \quad 1\right.}{} \quad \text { (1.5) }
\end{aligned}
$$

Here, $(k)=k^{2}=(2 m) \quad$ and $q=(q ;)$ is a four$m$ om entum, $w$ ith $w a v e$ vector $q$ and $M$ atsubara frequency ( integer). In an analogous way, one can show that in the particle-particle channel the contributions of the vertex corrections and of the two-particle e ective interactions other than the rung vanish for our choice of the potential.

It is thus evident from these considerations that, $w$ ith our choice of the ferm ionic interaction, in the strongcoupling lim it the skeleton structure of the diagram $m$ atic theory can be constructed only w ith the particle-particle ladder (1, 1.5 phis an in nite num ber of interaction vertices. A carefiul diagram $m$ atic analysis considered in detail in Ref. correspond to ferm ionic particle-particle ladders; (b) The interaction am ong bare com posite bosons is described by 4 -point, 6-point vertioes, and so on, which correspond to the product of $4 ; 6 ;:::$, ferm ionic bare $G$ reen's functions (w th one intemal four-m om enta integration). The correspondence rules for the bosonic $G$ reen's function and the 4 -point vertex are show $n$ in $F$ ig. 2.

In particylar, in the strong-coupling lim it (whereby j j 1) $l^{\frac{1}{1}}$ the particle-particle ladder 0 (q) has the follow ing polar structure

0 (q)
where we have used the de nition $\mathrm{B}^{2}=2+0$ for the bosonic chem ical potential ( $0=1=\left(m a_{F}^{2}\right)$ being the bound-state energy of the ferm ionic tw o-body problem ). $N$ ote that (apart from the residue being di erent from unity) the expression (1, (1) resem bles a \free" boson propagator $w$ th $m$ ass 2 m . The (four-point) e ective twoboson interaction reads instead

$$
\begin{aligned}
& a_{2}\left(q_{1}::: q_{4}\right)=q_{1}+q_{2} ; q_{3}+q_{4} \quad \underline{V}^{2} \frac{2}{V} \\
& \quad X \\
& G^{0}(k) G^{0}\left(k+q_{2}\right) G^{0}(k+q \quad q) G^{0}\left(k+q_{4}\right):
\end{aligned}
$$

Here $G^{0}(k)=\left[i!\text { n } \quad \mathrm{k}^{2}=(2 \mathrm{~m}) \quad\right]^{1}$ is a bare ferm ionic $G$ reen's function ( $!_{n}$ being a ferm ionic $M$ atsubara frequency). $N$ ote that the interaction ( $(\overline{1}, \overline{1})$ depends on wave vectors as well as on $M$ atsubara frequencies, revealing in this $w$ ay the com posite nature of the bosons. The factor of 2 in the de nition ( $\mathbf{i}_{1}^{-1} \bar{T}_{1}$ ) corresponds to the two di erent sequences of spin labels that can be attached to the four ferm ionic $G$ reen's functions, as show $n$ graphically in Fig.

F IG . 1. P article-particle ladder. Four-m om enta are indicated and spin labels are represented by up and down arrow s. D otted lines represent the interaction potential and full lines the ferm ionic bare single-particle G reen's functions.

(a)

(b)

F IG . 2. G raphical correspondence (a) between the bare propagator for com posite bosons (represented by a thick line) and the ferm ionic particle-particle ladder, and (b) between the e ective two-boson interaction and the four-point vertex.

In the strong-coupling lim it j j 1, a typicalvalue of the tw o-boson e ective interaction is obtained by setting $q_{1}=\quad 4=Q$ in Eq. $\left.]_{1}^{-1}, 7_{1}\right) . O$ ne gets:

$$
\begin{equation*}
a_{2}(0)=2 \quad \underline{V}^{2} \frac{m^{2} a_{F}}{8}{ }^{2} u_{2}(0) \tag{1.8}
\end{equation*}
$$

where ${ }^{\text {"4, }}$

$$
\begin{equation*}
\mathrm{u}_{2}(0)=\frac{4\left(2 \mathrm{a}_{\mathrm{F}}\right)}{2 \mathrm{~m}}: \tag{1.9}
\end{equation*}
$$

The factorm ${ }^{2} \mathrm{a}_{\mathrm{F}}=(8)$ in Eq. $(\underline{1} \mathbf{- 1}, \overline{9})$ re ects the di erence between the true bosonic propagator and the particleparticle ladder in the strong-coupling lim it [cf. also Eq. (1.. $\mathbf{6})]$. $\quad \mathrm{O}$ wing to this di erence, $u_{2}(0)$ given by Eq. (1.9) (and not $\mathfrak{a}_{2}(0)$ given by Eq. (1. $\left.0_{1}\right)$ ) has to be identi ed w ith the boson-boson interaction at zero fourm om enta. N ote that $\mathrm{u}_{2}(0)$ is positive in the strongcoupling lim it, thus ensuring the stability of the bosonic system.

Recall further that the scattering length $a_{B}^{B o m} w$ thin the Bom approxim ation, obtained for a pair of true bosons (each ofm ass 2 m ) m utually interacting via a tw obody potentialw ith Fourier transform $u_{2}(0)$ at zero wave vector, is given by $a_{B}^{B \circ o m}=2 m u_{2}(0)=(4)$. Equation (1.9) then yields the follow ing relation betw een the bosonic and ferm ionic scattering lengths w ithin the B om approxim ation:

$$
\begin{equation*}
a_{B}^{\text {Bom }}=2 a_{F}: \tag{1.10}
\end{equation*}
$$

 ferm ionic self-consistent $T \mathrm{~m}$ atrix approxim ation (w hich corresponds to the bosonic H artree Fock approxim ation in the strong-coupling lim it). In that reference, the result ( $\left(\overline{1} . \overline{1} 0^{\prime}\right)$ w as erroneously regarded to be the fullvalue of the scattering length $a_{B}$ for a \dilute" system of com posite bosons. W ew ill, in fact, show in the next section that the result ( diagram s- are properly taken into account.

Besides the four-point vertex $(1-7.1)$, the com posite nature of the bosons produces (an in nite set of) additional vertices. O ne can show that all interaction vertices can be neglected in com parisen $w$ ith the four-point vertex in the strong-coupling lim 进望 In this lim it, one can thus construct all diagram s representing the tw o-particle $G$ reen's function in the particle-particle channel in term s only of the bare ladder and of the four-point interaction vertex. This is precisely what one would expect on physical grounds, since the interactions involving $m$ ore than tw o bodies becom e progressively lesse ective as the com posite bosons overlap less when approaching the strongcoupling lim it.

> II. NUMERICAL RESULTSFOR THE SCATTERING LENGTH OF COMPOSITE BOSONS

In three dim ensions the scattering length a characterizes the low-energy collisions for the scattering from an
ordinary potential. For the $m$ utual scattering oftw o particles (each of $m$ ass M ), a can be expressed by the relation $t(0)=4 \mathrm{a}=\mathrm{M}$ in term $s$ of the ordinary $T \mathrm{~m}$ atrix $t(0)$ in the lim it of vanishing wave vector. In particular, $w$ thin the Bom approxim ation $t(0)$ is replaced by the Fourier trasform $u(0)$ of the interparticle potential for vanishing wave vector.

For com posite bosons, the $T$ m atrix $t_{B}\left(q_{1} ; q_{2} ; q_{3} ; q_{A}\right)$ is de ned by the follow ing integral equation (cf. Fig. in in :
$t_{B}\left(q_{1} ; q_{2} ; q_{3} ; q_{4}\right)=u_{2}\left(q_{1} ; q_{2} ; q_{3} ; q_{4}\right)$

$$
\begin{align*}
& \frac{1}{V}{ }_{q_{5}}^{X} u_{2}\left(q_{1} ; q_{2} ; q_{5} ; q_{1}+q_{2} \quad q\right) 0\left(q_{5}\right) 0\left(q_{1}+q_{2}\right. \\
& t_{B}\left(q_{1}+q_{2} \quad q_{i} ; q_{5} ; q_{3} ; q_{4}\right) \tag{2.1}
\end{align*}
$$

$w$ here $u_{2}$ is proportional to the e ective tw o-boson interaction of Eq. $(1 . \overline{4})$ :

$$
\begin{align*}
& u_{2}\left(q_{1}::: q_{4}\right)=\frac{1}{V}_{k}^{x} \\
& G^{0}(k) G^{0}\left(k+q_{2}\right) G^{0}(k+q \quad q) G^{0}\left(k+q_{4}\right): \tag{22}
\end{align*}
$$

$$
\begin{aligned}
& x+x+x+0 \times x \\
& +\cdots
\end{aligned}
$$

FIG.3. $T$ m atrix diagram $s$ for the com posite bosons. $H$ eavy lines and squares are de ned as in $F$ ig. 2.

Sim ilarly to the problem of point-like bosons, we dene the scattering length $a_{B}$ for the com posite bosons (each of $m$ ass $2 m$ ) in the strong-coupling lim it and for vanishing density, by setting $t_{B}(0)=4 \quad a_{B}=(2 m)$. Here $t_{B}(0)=\left(8=\left(m^{2} a_{F}\right)\right)^{2} t_{B}(0)$ and $t_{B}(0) \quad t_{B}(0 ; 0 ; 0 ; 0)$. $T$ he rescaling between $t_{B}(0)$ and $t_{B}(0)$ is due to the di erence betw een the true bosonic propagator and the particle-particle ladder in the strong-coupling lim it. T he sam e rescaling is consistently used_when de ning the boson-boson interaction [cf. Eqs. (1. $(\mathbb{q})$ and $(1,7)]$.

To the low est order in the e ective interaction betw een the com posite bosons, we can replace $t_{B}(0)$ by $u_{2}(0)$ and w rite $u_{2}(0)=4 a_{B}^{\text {Bom }}=(2 \mathrm{~m})$, within the Bom approxi$m$ ation. C om parison $w$ ith Eq. (1.9) yields then the value $a_{B}^{B \circ m}=2 a_{F}$, as anticipated by Eq. (1 $\left.\overline{1} \overline{0}\right)$.

In order to obtain the exact value of $\bar{t}_{B}$ (0) (and hence of the scattering length $a_{B}$ ), it is convenient to determ ine rst the auxiliary quantity $t_{B}(q ; q ; 0 ; 0)$ by solving the follow ing closed-form equation

$$
\begin{align*}
& t_{B}(q ; ~ q ; 0 ; 0)=u_{L}(q ; \quad q ; 0 ; 0)  \tag{2.3}\\
& \frac{1}{V}_{q^{0}}^{X} u_{2}\left(q ; q ; q^{0} ; q^{0}\right) ~ o\left(q^{0}\right) ~ o\left(q^{0}\right) t_{B}\left(q^{0} ; ~ q ; 0 ; 0\right) ;
\end{align*}
$$

obtained from Eq. (2, by setting $q_{i}=q=q$ and $q_{3}=q_{4}=0$. This integral equation can be solved by
standard num ericalm ethods, e.g., by reverting it to the solution of a system of coupled linear equations. N ote that, since we are here interested in the calculation of a tw o-boson quantity, the zero-density lim it has to be taken in Eq. (2,31). This in plies that $B=0$ (or equivalently $2=0$ ) and $T=0 ?^{?} \mathrm{~T}$ he discrete bosonic frequency becom es a continuous variable accordingly.
$N$ um erical calculation of Eq. (2, 3, requires us to introduce a nite-size $m$ esh for the variables ( $\dot{q} j$ ) and
( $\dot{q}^{0} j{ }^{0}$ ), w ith the angular integral over $\hat{q}^{0}$ a ecting only the function $u_{2}(q ; q ; q ; q)$. Equation (2, 2 is thus reduced to a set of coupled equations for the unknowns $t_{B}(\dot{q} \dot{j} ; \dot{q} \dot{j} \quad ; 0 ; 0)$, which were solved by the $N$ ew tonRalphson algorithm with a linear interpolation for the integrals over $\dot{\mu}^{0} j$ and ${ }^{0}$. In this way, we are led to the result

$$
\begin{equation*}
a_{B}=0: 75 a_{F} \tag{2.4}
\end{equation*}
$$

w ithin an estim ated 5\% num erical accuracy.
To sum $m$ arize, we have shown that, in the strongcoupling lim it of the ferm ionic attraction, the value $a_{B}=$ $0: 75 \mathrm{a}_{\mathrm{F}}$ is obtained by a correct sum $m$ ation of the bosonic T m atrix diagram s for the com posite bosons which form asbound-ferm ion pairs. This theoreticalprediction could be tested against the experim ental data w ith ultracold Ferm iatom sin a trap, when bosonic molecules are obtained by a Feshbach resonance.

${ }^{5}$ N . A ndrenacci, P . P ieri, and G .C . Strinati, Eur. J. P hys. B 13, 637 (2000).
${ }^{6}$ The choice of the \contact" potential (1-21) does not allow the ferm ionic attraction to extend over a nite range. If a nite-range ferm ionic attraction would instead been adopted, the e ective boson-boson potential in the strongcoupling lim it would acquire an attractive part which w ould dom inate over the usual repulsive part due to $P$ auli principle, in the sense that the bosonic scattering length associated w ith the attractive part w ould not vanish in that lim it. $T$ he attractive part would thus lead to an instability of the bosonic system when the nite-range ferm ionic attraction gets su ciently strong. To avoid th is instability, a condition of the type $0 \quad k_{0}^{2}=(2 m)$ has to be im posed on the BE lim it, $w$ here $k_{0}$ is the $w$ ave vector specifying the nite range of the potential and 0 is the bound-state energy of the ferm ionic tw o-body problem [cf. footnote 43 of $R$ ef. ' 41 '1]. In this context, 进 is worth $m$ entioning the work by G. R opke et al.
$\mathbb{P}$ hys. R ev. Lett. 80 , 3177 (1998)] w here it has been show $n$ that, in the strong-coupling lim it, there exists a com petition between pair and quartet condensation in a Ferm i liquid $w$ ith nite-range attraction. It is then clear that adopting a nite-range ferm ionic potential m erely $m$ akes the BCSBE crossover $m$ ore involved, and it is thus not relevant for the present purposes.
${ }^{7}$ A precise de nition of $w$ hat is $m$ eant by strong coupling is as follow s . In this lim it, the binding energy 0 is much larger than the density and tem perature $T$. U nder this condition, the ferm ion ic chem icalpotentialapproaches the value $\quad 0=2$ and j j 1.
