#### Abstract

The role ofdim ensionality (Euclidean versus fractal), spatialextent, boundary e ects and system topology on the e ciency of di usion-reaction processes involving two sim ultaneously-di using reactants is analyzed. W e present num erically-exact values for the $m$ ean time to reaction, as gauged by the $m$ ean walklength before reactive encounter, obtained via application of the theory of nite $M$ arkov processes, and via $M$ onte $C$ arlo sim ulation. A s a general rule, we conclude that for su ciently large system s , the e ciency of di usion-reaction processes involving tw o synchronously di using reactants (tw o-w alker case) relative to processes in which one reactant of a pair is anchored at som e point in the reaction space (one walker plus trap case) is higher, and is enhanced the low er the dim ensionality of the system. This di erentiale ciency becom es larger with increasing system size and, for periodic system s , its asym ptotic value $m$ ay depend on the parity of the lattice. Im posing con ning boundaries on the system enhances the di erential e ciency relative to the periodic case, while decreasing the absolute e ciencies ofboth tw o-w alker and one w alker phis trap processes. A nalytic argum ents are presented to provide a rationale for the results obtained. The insights a orded by the analysis to the design of heterogeneous catalyst system $s$ is also discussed.

The in uence of the interplay between spatial extent and system dim ensionality on the reaction e ciency when reactants are undergoing random displacem ents on a nite lattice， w ith an irreversible reaction occurring on rst encounter has attracted considerable interest
 where one of the two reaction partners is anchored at som e point in the reaction space a novel feature addressed $m$ ore recently is $w$ hen both reaction partners are allow ed to di use sim ultaneously $\left[\begin{array}{ll}{[1,1} \\ \hline\end{array}\right.$

$$
\begin{equation*}
A+A!\quad 2 S \tag{1}
\end{equation*}
$$

where A denotes a site occupied by a di using reactant m olecule and $S$ a free site，as opposed to the schem e

$$
\begin{equation*}
A+T!S+T \tag{2}
\end{equation*}
$$

in which T denotes a site occupied by an im m obile target m olecule（trap）．In this paper， we shall refer to the schem e described by Eq．（ $\overline{1}$＇）as the \tw owalker（ 2 W ）case＂，while the kinetics described by Eq．（ $\overline{\underline{Z}}$ ）w ill be term ed \onew alker plus trap（1W T）case＂．

In Refs．［1］，＇，＇ī1］，particular attention w as focused on processes taking place on square－planar lattioes sub ject to various boundary conditions．It was found that signi cant di erences in reaction e ciency resulted depending on whether one or both reactants were di using．The ob jective of the present study is to inquire to what extent these results are generic and，if so， how they depend on the geom etry of the support．T he latter willbe characterized，in tum， by the size，the em bedding dim ension，the intrinsic dim ensionality，and by the topological invariants．Am ong these，for two－dim ensional ob jects（surfaces）the Euler characteristic
$=F \quad E+V$ where $F$ is the num ber of faces，$E$ the num ber ofedges and $V$ the num ber of vertioes is especially signi cant．In each case，the role of the boundary conditions will also be assessed．

The $m$ ean walklength of a di using species before encountering a coreactant is a natural $m$ easure of the tim e scale of a di usion－reaction process．Let hni be the m ean walklength before the irreversible reaction takes place in the $1 \mathrm{~W} T$ case（ Eq ．（2⿹勹巳））．Let hni $\mathrm{i}_{2}$ be the corresponding quantity for the 2 W case（Eq．（Ĩ）））．The quantities hni $i_{1 ; 2}$ are obtained by averaging over statistical realizations com prising all di erent initial con gurations of both reaction partners．The sm aller the value of hni $i_{1 ; 2}$ ，the higher the e ciency of the reaction．

A point that $w$ ill recur frequently in the follow ing is that the reaction in the 2 W case can occur via two di erent channels．In the rst scenario，the tw o reaction partners happen to occupy adjacent sites on the lattioe，and（w ith a certain probability）in their next，mutual displacem ent they undergo a collision．In the second channel，an intervening lattice site separates the two reactants and，in their subsequent $m$ otion（again，$w$ ith a certain prob－ ability），both attem pt to occupy that sam e（vacant）lattice site．A s we shall see，one or both of these reaction channels can pertain，depending on the choige ofboundary conditions and the parity of the total number of lattice sites N ．Since both $\mathrm{hn}_{1}$ and $\mathrm{hn} \mathrm{i}_{2}$ depend on the characteristics of the lattioe and on the boundary conditions，it will therefore be $m$ ore appropriate to choose as $m$ easure of the relative e ciency of the 2 W process the ratio $\mathrm{hn} \mathrm{i}_{1}=\mathrm{hn} \mathrm{i}_{2}$ ．
There are both theoretical and experim ental reasons for studying the in uence of geom－ etry and boundary conditions on the e ciency of di usion－reaction processes．First，one
would like to isolate e ects that are independent of the boundaries of the dom ain in which the di usion-reaction processes take place, and for this, periodic boundary conditions are usually im posed. O ver the last several years, how ever, there has been an avalanche of experim ental work published on the study of di usion-reaction processes in microheterogeneous $m$ edia [్ర1] ( $m$ ioelles, clays, zeolites, etc.), w ith system $s$ of nite extent (nanosystem $s$ ) show ing non-classical behavior (i.e., departures from \m ean eld" behavior). Therefore, in the present study we have also exam ined in tandem with periodic boundary conditions, system s sub ject to con ning boundary conditions. Speci cally, in adopting con ning boundary conditions, one im poses the condition that if a di using particle attem pts to exit the lattice from a given boundary site, it is sim ply reset at that boundary site.

The calculations perform ed in this paper are of two kinds. First, we use the theory of nite $M$ arkov processes to com pute hni and hni $i_{2}$, for m all, nite lattioes sub ject either to periodic or con ning boundary conditions. The advantage of this approach is that one obtains num erically-exact solutions to the problem under study and, in certain cases, one can construct closed-form analytic solutions. M irroring this, we also perform M onte C arlo calculations, rst validated by com parison $w$ th the $M$ arkov results and then used to analyze system s of large spatial extent.

The plan of this paper is as follow s. In Secs. $\bar{a}$ \{ $\left\{\begin{array}{l}\text { in } \\ \text {, }\end{array}\right.$, we consider successively lattioes of Euclidean dim ension $d=1, d=2$ and $d=3$, as well as the Sienpinski gasket, a lattioe of fractal dim ension $D=\ln 3=\ln 2$. The in uence of size e ects, boundary conditions and other related topological features such as the connectivity and the Euler characteristic is discussed in each dim ension. The $m$ ain conclusions are sum $m$ arized in Sec.' ${ }_{-1}^{1}$.

## 2. EUCLIDEAN D IM ENSION, $d=1$

The 1W T problem on a d=1 nite lattioe sub ject to periodic boundary conditions was solved by M ontroll [ब్ర $]$ analytically. The result he found was:

$$
\begin{equation*}
\mathrm{hn} \mathrm{i}_{1}=\frac{\mathrm{N}(\mathbb{N}+1)}{6}: \tag{3}
\end{equation*}
$$

w here N is the total num ber of sites in the lattice.
The solution for the case of tw o walkers in $d=1$ for a lattioe sub ject to periodic boundary conditions can be obtained in closed form by form ulating the problem as a classical ruin problem and solving the correspondence di erence equations', '[]. The result is

$$
\begin{array}{ll}
\mathrm{hni}_{2}=\begin{array}{ll}
N(\mathbb{N}+1)(\mathbb{N}+2)=12(\mathbb{N} & \text { 1) for } N \text { even } \\
(\mathbb{N}+1)(\mathbb{N}+3)=12 & \text { for } N \text { odd }
\end{array} \text { : } \tag{4}
\end{array}
$$

This result can also be obtained via the theory of nite $M$ arkov processes by calculating num erically-exact values of $\mathrm{hn}_{2}$ for a series of $\mathrm{d}=1$ lattices. From these results pattems can be recognized from which one can construct the above closed-form analytic solution.
$W$ e notice a di erence in the expression for hniz for even and odd values of $N$ also found
 We nd that this qualitative di erence in behavior between even and odd lattioes is alw ays m anifested if periodic boundary conditions are considered, but not if con ning boundary conditions are im posed. This behavior can be rationalized by exam ination of sm all odd and even lattioes. The key to this di erence is in the reaction $m$ echanism, which happens either via nearest-neighbor collision (NNC) or via sam e-site occupation (SSO).

C onsider the two periodic lattices of size $N=3$ and $N=4$ shown in $F$ igs. ind and For N = 3, assume that we place a walker on site 1 and another one on site 3. C oncemed only w th the concerted $m$ otions leading to reaction, one can see that reaction takes place by SSO ifboth walkers jum $p$ to site 2, or by NNC if they attem pt to exchange positions. Thus, both reaction channels are open. N ow consider the periodic $N=4$ lattice and place again the walkers on sites 1 and 3. The reaction can proceed by SSO ifboth walkers jum p to site 2 or site 4 after one tim e step. O therw ise, they will alw ays be tw o sites apart, essentially follow ing each other in the lattice. This $m$ eans that starting $w$ ith the initial con guration of walkers on sites 1 and 3, the only allow ed reaction channel is SSO. On the other hand, if sites 1 and 2 are chosen as the initialpositions of the walkers, orm ore generally any adjacent pair of sites, reaction can only occur by NNC. This is true because any concerted motion will either lead to NNC or the walkers will rem ain nearest-neighbors after each tim e step. $M$ ore generally, it is easily seen that for an even lattioe only one of the reaction channels is active for any given initial con guration, whereas for odd lattioes, both can take place. This phenom enon will hereafter be referred to as the \even-odd e ect".
$W$ e next consider the $1 \mathrm{~W} T$ and the 2 W problem s in a $d=1$ lattioe subject to con ning boundary conditions. From M arkov theory, one obtains for the 1W $T$ :

$$
\begin{equation*}
\operatorname{hni}_{1}=\frac{\mathrm{N}(\mathbb{N}+1)}{3}: \tag{5}
\end{equation*}
$$

A ccording to this form ula, the reaction e ciency is reduced by a factor of 2 w ith respect to the periodic case described by Eq. ( $\overline{3}, \mathbf{y})$ for all system sizes. The reason is that the lattioe w ith con ning boundaries and a trap $T$ can be decom posed into two disconnected periodic lattices, each of them w ith a trap, since the parts of the lattice on either side of $T$ do not com $m$ unicate ${ }^{1}$. This equivalence is ilhustrated in $F$ ig. 'Lia for a con ning lattice $w$ ith $N=4$. The weighted size of all equivalent periodic lattioes resulting from the di erent positions of the trapping site $T$ is larger than N. Sím ilar argum ents are expected to apply in higher dim ensions. Thus, con nem ent always reduces the e ciency of the reaction.

A sfor the 2W problem, no closed form expression sim ilar to Eq. (4, iq has yet been derived for the case of con ning boundary conditions. H ow ever, values of hni for this case could be calculated num erically using both the $M$ arkov $m$ ethod and $M$ onte $C$ arlo sim ulations. A s in the 1W T case, the e ciency is sm aller than in the periodic lattice case, but the increase in $\mathrm{hn}_{2}$ when con nem ent is im posed is sm aller than the factor of 2 found in the 1 W case for all values of the lattice size N larger than $\mathrm{tw} \mathrm{o}^{2}$, approaching a value close to 1.70 from below in the asym ptotic lim it (not shown). O nce more, an equivalence $w$ ith the periodic case can be established here. H ow ever, the di erence w ith the 1W T case is that now the size of the equivalent periodic lattioes uctuates in tim e, as it depends on the instantaneous distance. These lattioe size uctuations possibly explain why the loss ofe ciency is sm aller in the 2 W case when one sw itches from periodic to con ning boundary conditions.
$W$ e notice that no even-odd e ect is to be expected in the con ning case. This is illustrated in Fig. both walkers jum p to site 2 . If both walkers jum p to the left, then the walker on site 3 w ill jum $p$ to site 2, but the walker on site 1 will not $m$ ove. Both walkers occupy now adjacent

[^0]sites and NNC becom es possible at the next tim e step. For the other sym m etry-distinct intialcon guration w ith walkers at sites 1 and 2, one can form ulate an analogous sequence of jum ps leading to SSO. Thus, for a given initial condition, the im position of con ning boundary conditions allows both reaction channels on an even-site lattice, whereas w ith periodic boundary conditions only one of them is realized.

Figure' function of the lattice size N . It reveals an im portant feature, seen for allE uclidean lattices studied regardless ofdim ension or class ofboundary conditions ${ }^{3}$. The curve vs. N exhibits a steep increase initially with increase in $N$ but then it \attens out" and appears to be saturating at a particular lim ting value $1 \quad \lim _{\mathrm{N}}!1$. . The $\lim$ titing value ${ }_{1}$ is di erent for di erent dim ensions, but the sam e steep increase follow ed by a very gradual increase to a lim iting value is found. For the periodic case in $d=1$, the num erical evidence suggests that the curve is approaching a value close to 2 ; upon inspection of the analytic form of the solutions given by Eqs. ( $\overline{3}_{1}^{-1}$ ) and ( exactly 2. T his is related to the fact that, due to the translational invariance of the lattioe, the 2 W problem can be reduced to an equivalent 1 W T problem, and the e ective di usion coe cient for the latter becom es tw ice as large in the large $N$ lim it tī].

A second feature revealed by a closer exam ination of the analytic form for in the periodic case is that the increase $w$ ith size is staircase-like since takes the sam e value for two consecutive odd and even values of $N$ [ ${ }_{i}^{1}, 1$. This consequence of the even-odd e ect characteristic of the periodic case is not seen at the scale of resolution of F ig. $1{ }_{10} \mathrm{j}$, and is actually unim portant for the qualitative behavior over su ciently large $N$ intervals. Unlike toroidal (periodic) lattices in higher dim ensions, the even-odd e ect in one dim ension does not lead to di erent asym ptotic values ${ }_{1}^{\text {even }}$ and ${ }_{1}^{\text {odd }}$ depending on whether only even or only odd lattices are considered for the com putation of the respective walklengths.

In general, plotting the hn $i_{1}$ vs. the hn $i_{2}$ data forsu ciently large values of $N$, as displayed in $F$ ig. 'i $\overline{-1}$, is a convenient way of determ ining the saturation value 1 . The slope value from a least-squares curve $t$ for periodic lattioes is 1.97 , in good agreem ent w th the exact analytical value, and 2.35 for con ning lattioes.

## 3. EUCLDEAN D IM ENSION,d=2

A square-planar lattioe w ith periodic boundary conditions is topologically equivalent to a torus and has an Euler characteristic of 0 . Results in $d=2$ have already been reported for the case of a square-planar lattice sub ject to periodic boundary conditions [1] [1]. Figure ${ }_{1}{ }_{-1}^{1}$ show s clearly the behavior of in the large lattice lim it, which is di erent for odd and even lattioes. In Ref. [1]1], analytipal evidence was provided to show that the asym ptotic lim it of for odd lattioes is ${ }_{1}^{\text {odd }}=\overline{2}$.
A smentioned in the Introduction, surfaces are characterized topologically not only by their Euclidean dim ension but also by their Euler characteristic. Thus, it is also of interest to consider non-toroidal surfaces with Euler characteristic 0 . In particular, for the sphere and the fam ily of polyhedra hom eom orphic to it, one has $=2 . \mathrm{W}$ e shall consider two exam ples, the rst of which is the case of di usion-reaction processes on the surface of the P latonic solids. O ne of the reasons $m$ otivating the study of such polyhedral system $s$

[^1]is that they m im ic some features of real-w orld solid catalysts where the reaction takes place on particular crystallographic faces of the solid. In earlier work [8i], the vertioes of the $P$ latonic solids were used as the allow able particle positions. The $m$ ovem ent of each particle was perm itted along any adjoining edge. In the present study, we report the results of the calculation using the faces of the P latonic solids; the particle $m$ oves from face to adjacent face, crossing only one edge at each tim e step. The relationship betw een these tw o calculations is reciprocal. In form al language, tw o polyhedra are dual if the num ber of faces of one of them equals the num ber of vertices of the other, and vice versa $[\underset{-1}{-9}]$. Recall that the tetrahedron has 4 faces and 4 vertioes and both faces and vertioes have a valency of 3 . The octahedron has 8 faces and 6 vertioes, and the hexahedron (cube) has 6 faces and 8 vertioes. $T$ he valency of the octahedron faces is 3 as is the valency of the cube vertioes. Likew ise, the valency of the octahedron vertioes is 4 as is the valency of the cube faces. Perform ing the calculation on the faces of the octahedron is equivalent to the calculation on the vertioes of the cube, and the sam e reciprocal relation holds true when exam ining the ioosahedron and the dodecahedron. Table in show results for $\mathrm{hn} \mathrm{i}_{1}$ and $\mathrm{hn} \mathrm{i}_{2}$ on the P latonic solids. A s can be seen, w th the exception of the octahedron, increases $w$ th $N$, in line w th the results for the square planar lattice.

It is instructive to view the results of the P latonic solids in tandem with their planar analogues. The tetrahedron, octahedron and hexahedron can be placed in correspondence w ith periodic planar lattices w th the sam e valency and sam e value of $N$; the dodecahedron and iossahedron have no periodic, planar analogues. In correspondence w th the tetrahedron and octahedron we constructed hexagonal lattices for com parison, while the hexahedron was com pared w ith a 23 square-planar lattice. T he tetrahedron and hexahedron have sm aller values than their planar analogues for the walklengths $\mathrm{hn} \mathrm{i}_{1}$ and $\mathrm{hn} \mathrm{i}_{2}$ but larger values of . Surprisingly all the walklength values for the octahedron and the 8 -site hexagonal lattice are identical. U pon further exam ination of this degeneracy, one nds that the values are identical because the connectivity of the octahedron is identical, site by site, w ith the connectivity of the 8 -site periodic hexagonal lattioe. These calculations show, surprisingly, that the connectivity of the lattioe seem $s$ to play a relatively more im portant role than the Euler characteristic in determ ining the value of the $m$ ean walklength.

W e also exam ined the in uence of im posing con ning boundary conditions on the planar lattice analogues of the $P$ latonic solids. O w ing to the fact that the connectivity of sites on the boundary of these ( nite) lattioes changes, the values ofhn $i$ and hn $i_{2}$ change. The values of hni $i_{2}$ for all three planar analogues are only slightly larger than for the case where periodic boundary conditions are im posed. On the other hand, the values of hn $i_{1}$ are considerably larger than the values of $\mathrm{hn}_{1}$ calculated for periodic boundary conditions; for the $\mathrm{N}=4$ hexagonal lattice, the $N=8$ hexagonal lattice and the $N=23$ square-planar lattice, the value of $\mathrm{hni}_{1}$ increases by a factor of 3,4 and 2 , respectively. Thus, in sm all system s , changes in the boundary conditions have a signi cant e ect on the calculation of hni, but less so on the calculation of $\mathrm{hn}_{2}$. O verall, the in uence ofboundary conditions on both the 1W T and 2 W cases for these planar analogues of the P latonic solids is m ore drastic than is the case for a ( m alli) $d=1$ lattice. This is re ected in the value of , which increases by a larger factor here than in the $d=1$ case when con ning boundary conditions are im posed.

In order to em ulate large-size system s , we have studied di usion-reaction processes on the surface of a cube, which is also of Euclidean dim ension $d=2$ and Euler characteristic
$=2$. The particle is con ned to the surface, and each face of the cube is divided into a

[^2]number of sites is $\mathrm{N} \quad \mathrm{N} \quad 6$. N ote that for $\mathrm{N}=1$ the previous case of an hexahedron is recovered. The valency of each site is exactly four, keeping in $m$ ind that som e $m$ ovem ents of the walker will take it to a di erent face.

Figure ' 5 , sum $m$ arizes the $d=2$ results in the large lattice lim it. It is seen that, on the surface of a cube, the di erentiale ciency , given by the slope of the curve hnip vs. $\mathrm{hni}_{2}$, is larger than on a periodic but sm aller than on a con ning square planar lattioe. A s expected, the e ciency of 1W T processes is once again decreased in a m ore pronounced way when con nem ent is im posed. The even-odd e ect is not seen for processes on the surface of a cube or for planar lattioes sub ject to con ning boundary conditions. On the cube, an argum ent analogous to the one put forth for $\mathrm{d}=1$ applies, except that the walkers on the cube surface have two additional degrees of freedom. H ow ever, this has no in uence on the fact that, irrespective of the starting con guration, both NNC and SSO m ay still take place because of the the walkers' ability to traverse edges and thereby $m$ igrate to di erent faces of the cube.
4. H IG HER D IMENSIONSAND FRACTALSTRUCTURES

### 4.1. Euclidean D im ension, $d=3$

 $\mathrm{d}=3$ cubic lattioe sub ject to periodic boundary conditions. W e have extended this study to calculate $\mathrm{hn}_{1}$ and $\mathrm{hn} \mathrm{i}_{2}$ for both periodic and con ning boundary conditions by m eans of $M$ onte $C$ arlo simulations. In $d=3$, the even-odd e ect is even $m$ ore pronounced than in the square-planar lattice case, as $m$ ay be seen in $F$ ig. ${ }_{-1}{ }_{-1}$. From the least-square ts we infer ${ }_{1}^{\text {even }}=0: 72$ and ${ }_{1}^{\text {odd }}=1: 22$. This suggests that the even-odd e ect is enhanced with increasing dim ensionality of the hypercubic lattice. N ote also that $1<1$ for even lattioes, the only case where the di erentiale ciency goes below unity except for the octahedron.

For con ning boundary conditions, another signi cant result for $\mathrm{d}=3$ is show n in F ig. ${ }_{1} i_{1}$. A s is evident, approaches its lim iting value from above, and ${ }_{1}$ is found to be about 1.42 in this case. In all previous cases, nam ely the $d=1$ and $d=2$ cases $w$ ith both types ofboundary conditions, the graphs had the general features ofF ig. 1 below .

### 4.2. Fractal D im ension, D $=\ln 3=\ln 2$

From the results presented for the cases $d=1$, the $d=2$ square-planar lattice, and $d=3$ cubic lattioe sub ject to con ning boundary conditions, one can infer that, with increasing dim ensionality $d$ of the lattice, 1 decreases $m$ onotonically taking the values 2.35, 1.66 and 1.42, respectively, for $d=1,2$ and 3 . In order to assess further the role of dim ensionality and of con nem ent, one can next consider the case of a Sienpinski gasket, whose ram i ed selfsim ilar structure is described by an intrinsic non-integer dim ension $D=\ln 3=\ln 2^{\prime}$ 1:585. The gasket can be constructed hierarchically as a lim it of successive generation gaskets. Each generation gasket is characterized by an index i. The i= 0 generation is an equilateral triangle whose 3 vertices play the role of lattice sites, ie. allow able reactant positions. The i = 1 generation can be constructed by appending to each of the bottom vertioes of the prim ary triangle an additionalequilateral triangle so that the upper vertices of the appended
triangles are identicalw the the bottom vertioes ofthe prim ary one and the appended triangles have a com $m$ on bottom vertex. The $i=2$ generation is constructed by perform ing the sam $e$ procedure on the resulting structure, i.e. appending tw ice the sam e structure at its bottom, and so on. Thus, at a given generation step, the num ber of identical substructures increases by three while the linear size doubles, yielding the above value of D for the Sienpinski gasket obtained when i! 1 . For each generation, the lattice sites are identi ed with the three apex vertices located at the outm ost comers of the corresponding gasket and w ith the com $m$ on vertioes of any pair of adjacent triangles in the gasket. The num ber of sites in the ith generation gasket is $N=N(i)=(3=2)\left(3^{i}+1\right)$.
$T$ he gasket shares som e com $m$ on features $w$ ith a square-planar lattice. $F$ irst, the em bedding dim ension is the sam e, viz. $d=2$. Secondly, except for the vertex sites on the gasket, the valency of all other sites is $v=4$; increasing the size of the gasket decreases the fraction of lattioe sites not having a valency of 4 . A ll sites on a square-planar lattice sub ject to periodic boundary conditions have a valency $v=4$. On im posing con ning boundary conditions on the square-planar lattioe, all interior sites w ill have valency $\mathrm{v}=4$, vertex sites w ill have valency $\mathrm{v}=2$ and boundary sites w ill have valency $\mathrm{v}=3$; the percentage of vertex and boundary sites on a square-planar lattioes also decreases w ith increase in lattice size. $T$ hus, both for the gasket and for a nite square-planar lattice sub ject to con ning boundary conditions, the relative im portance of interior sites on the statistics increases with increasing lattice size. F inally, one can easily convince oneself that in the 2W case both the SSO and NNC channels can take place for any given con guration of the walkers on the gasket, so no even-odd e ect is expected here either.

In view of the above resemblances, it is interesting to inquire to what extent the results obtained for the relative e ciency on the gasket are sim ilar to those for the square lattice with con ning boundary conditions. To this end, hni and $\mathrm{hni}_{2}$ and their ratio were calculated using the theory of nite $M$ arkov processes for $N=6,15$, and 42 and via $M$ onte $C$ arlo sim ulations for all generations up to $\mathrm{N}=3282$. For the 1 W T case, a closed-form analytic expression for the walklength is already available if the trap is $m$ aintained at one of the apex vertioes of the nth generation gasket, nam ely [1-ī]

$$
\begin{equation*}
\operatorname{lni}_{1 ; a}=\frac{3^{i} 5^{\text {i+ } 1}+4\left(5^{i}\right) 3^{i}}{3^{\text {i+1 }}+1}: \tag{6}
\end{equation*}
$$

In perform ing $M$ onte $C$ arlo sim ulations, the am ount of com puting tim e can increase dra$m$ atically $w$ ithin increase in gasket size $N$ thus lim iting the num ber of statistical realizations $\mathrm{n}_{\text {real }}$. In the $1 \mathrm{~W} T$ case, each realization com prises all sets of possible con gurations for the walker and the trap, while in the 2 W case, each realization com prises all sets of possible con gurations for the two indistinguishable walkers. The analytic expression of hni i; given in Eq. ( $\bar{\sigma})$ ) was used to test the accuracy of M C results for gasket sizes $N>123$, where the $M$ arkovian approach becom es cum bersom e due to the size of the relevant transition $m$ atriœes. It was found that, as N is increased, the num ber of realizations required to reach a given accuracy in $\mathrm{hni}_{1 \text {; }}$ w ith respect to the exact result given by ( $(\overline{\mathrm{G}})$ ) decreases signi cantly. For all values of $n_{\text {real }}$ given in $T a b l e \underline{12}_{2}^{2}$, the relative error tumed out to be $<0: 4 \%$ (data not show n ). Therefore, the results for $\mathrm{hn} \mathrm{i}_{1}$ and $\mathrm{hn} \mathrm{i}_{2}$ for large N displayed in Table 究 seem reliable enough to describe correctly the qualitative behavior of the e ciencies.

A though the convergence to a hypothetical saturation value is very slow in $N$, one notiges from Table' 1 = 1:66 for a con ning square lattioe. A ssum ing that keeps on increasing $m$ onotonically
w ith the gasket size N , a question of interest is whether approaches a saturation value less than the value 2:35 found for a $d=1$ con ning lattioe, or whether the asym ptotic value rem ains between the values 1:66 and $2: 35$, as one $m$ ight expect in view of the $m$ onotonic decrease of ${ }_{1}$ w th decreasing dim ensionality referred earlier.

## 5. CONCLUSIONS

In this work, results, both analytic and num erical, on the role of boundary e ects and of geom etric factors such as size, dim ensionality and topological invariants on the e ciency of encounter-controlled reactions have been obtained. Values for the $m$ ean walklengths hni $i_{1}$ and $\mathrm{hn} \mathrm{i}_{2}$ for the 1 W T and the 2 W case aswellas the relativee ciency have been com puted both for large lattioes and sm all size system s .

The relevance of considering in detail system s of restricted spatial extent is increasing, as it is now adays realized that heterogenous catalytic processes of great im portance take place on single crystallographic faces of solid catalysts where they can involve only a few tens of particles. D espite the fact that the num erical values obtained in this work for sm all system s are not universal, som e universal trends of a di erent kind have nevertheless been observed, e.g. the dependence (increasing, m onotonic, etc.) of on valency, connectivity and boundary conditions. In general, one has >1, implying that the reactive e ciency of tw o $m$ oving reactants is greater than a di using phus an im mobile one.

Tuming now to large-size system s , our results show that increases with increasing lattice size until it reaches a well-de ned lim iting value ${ }_{1}$. For a given lattice geom etry, this value decreases $w$ ith increasing dim ensionality. W ith the exception of the even cubic lattice, $1>1$.

For E uclidean lattioes of square-planar or cubjic sym $m$ etry and sub ject to periodic boundary conditions the value of ${ }_{1}^{\text {odd }}$ is exactly 2 and $\overline{2}$ in one ${ }^{4}$ and two dim ensions respectively, and about 1.22 in three dim ensions. O ne is tem pted to advapnce that this lastpnum bep is actually w thin the precision a orded by the sim ulations just $\overline{(3=2)}$. N ow , 1, $\overline{2}$ and $\overline{3}$ are the naturalm etrics of the lattioes here considered in, respectively, 1, 2 and 3 dim ensions. The results for ${ }_{1}^{\text {odd }}$ could then be particular cases of a universal expression: the ratio of the $m$ axim um distance that two sim ultaneously $m$ oving reactants can traverse in one tim e unit before they react or nd them selves in nearest neighbor positions, over the analogous quantity for the one reactant plus trap case. Further w ork is necessary to assert the validity of this con jecture and to understand why it manifests itself only for odd lattioes.

For a given system size, the $1 \mathrm{~W} T$ and the 2 W reaction e ciency becom es less e cient when con nem ent is introduced, but the decrease in e ciency is sm aller for the 2 W case, leading to an increased value of $w$ ith respect to the periodic case. This boundary e ect appears to becom e less signi cant w ith increasing system size, although it is not com pletely absent in the them odynam ic lim it.

The questions raised in this work and the results obtained constitute potentially useful elem ents in the im portant problem ofoptim aldesign of them icroreactors now adays involved in chem ical kinetics under nanoscale conditions. For instance, as seen in Sec. III, a sm all

[^3]catalytic surface in the form of a sphere or of a hexahedral surface hom eom orphic to it ( $=2$ ) would enhance the reaction e ciency as com pared to a surface hom eom onphic to a torus $(=0)$. These observations highlight the need to incorporate in the design such aspects as the geom etry of the $m$ icroreactor, which can enhance an increasingly e ective $m$ ixing of the reactants and hence an increased e ciency of the reaction itself. Finally, the role of the kinetics (linear vs. nonlinear) in $m$ odulating or enhancing the im portance of such factors is certainly a problem worth addressing and this study is underway.
