#### Abstract

W e show that ratchet e ects can occur in a glassy m edia of interacting particles where there is no quenched substrate. We consider sim ulations of a disordered binary assem bly of colloids in which only one species responds to a drive. W e apply an asym $m$ etric ac drive that would produce no net dc drift of an isolated overdam ped particle. $W$ hen interacting particles are present, the asym $m$ etric ac drive produces a ratchet e ect. A sim ple $m$ odel captures $m$ any of the results from sim ulations, including ux reversals as a function of density and tem perature.

PACS num bers: 82.70 D d, $05.40 .-\mathrm{a}, 05.70 \mathrm{Ln}$

In ratcheting system s , a dc current or ux arises upon application of a periodic drive, such as w hen the underlying potentialsubstrate is ashed, or, for a xed substrate, when altemating forces are applied [1] [1]. R atchet e ects, which can be detem inistic or stochastic in nature, have been studied in a wide variety of system s , including bi-
 granular transport [ilit and colloidal transport. In many of these system $s$, an underlying asymmetric potential acts to break the left-right spatial sym $m$ etry. A ltemative ratchet system $s$ that have recently been investigated [|్ర'] have sym $m$ etric substrates, and rely on ac drives to provide sym $m$ etry breaking. In each of these cases, the particles $m$ ove through som e form of xed substrate.

In this work we study a ratchete ect that arises due to the collective interactions betw een driven and non-driven particles in a system that does not contain a xed substrate. The particular system we consider is a binary m ixture of interacting repulsive particles which form a disordered or glassy m edia. These particles, referred to as the passive species, interact only w ith other particles, and do not respond to an applied ac drive. W e introduce a sm all num ber of a separate species of particles, term ed the active species, which respond both to the other particles and to the ac drive. U sing num erical sim ulations we dem onstrate that a ratchet e ect can be achieved for the active particles in this system when the coupling betw een the active and passive particles is strong enough and a sym $m$ etry breaking is introduced by $m$ eans of the ac drive. This is in contrast to a recent theoretical proposal of an asym $m$ etric drive ratchet which transports undriven superconducting vortioes ${ }_{\text {IG }}$ G]. In addition, for speci cac drives, we nd current reversals as a function ofdensity and tem perature. W e also show that the m agnitude of the ratchet e ect goes through a maxim um as a function of the num ber of active particles, due to the collective string-like $m$ otions of the particles.

W e explicitly dem onstrate a ratchete ect form ixtures of colloids. O ur system is sim ilar to recent studies of binary colloidalmodels driven with ac elds where one species of the colloids $m$ oves in the direction of the applied drive while the other species $m$ oves in the opposite direction $\left[\begin{array}{l}1 \\ 1\end{array}\right]$. $T$ hese studies have found interesting
collective e ects in which the moving particles organize into lanes. In extensive studies ofdriven di usive m odels [8id $]$, where the tw o species of oppositely m oving particles are placed on a lattioe, a rich variety of nonequilibrium phases were observed. Continuum models, with di erent portions of particles $m$ oving in opposite directions, have also been studied in the context of pedestrian ow s [19]. A rem arkable phenom ena term ed \freezing by heating," where the system can jam at higher tem peratures, has recently been observed in these types of system s [1] $\left.{ }^{-1} 0^{1}\right]$. Since individual colloids or groups of colloids can be manipulated easily w ith opticaltraps [1] [1] , colloidal system s are ideal for experim entally realizing a system in which only a fraction of the particles respond to the applied drive. T he active species could be created using charged or m agnetic colloids, while the passive particles would be charge-neutral or non-m agnetic. For exam ple, in recent experim ents, m agnetic colloids w ere driven $w$ ith ac [ $12 \overline{2} \bar{\prime}]$ and dc drives [1] $\left.{ }^{-1}\right]$ through a glassy assem bly of other non $-m$ agnetic colloids. It should also be possible to drive a fraction of the colloids using opticalorm agnetic traps.

W e consider a binary two-dim ensional (2D ) assem bly of colloids using the sam e sim ulation $m$ ethod as in our previous w orks $\left[1 \overline{4}_{1}^{\prime} 1 \bar{S}_{1}^{1}\right]$. T he overdam ped equation ofm $0-$ tion for colloid is

$$
\begin{equation*}
\frac{d r_{i}}{d t}=f_{i j}+f_{A C}+f_{T} \tag{1}
\end{equation*}
$$

where $f_{i j}=\quad P_{j \in i}^{N} r_{i} V\left(r_{i j}\right)$ is the interaction force from the other colloids, $f_{A c}$ is the force due to an applied driving eld, and f is a them al from from Langevin kicks. The colloids interact via a Yukaw a or screened Coulomb interaction potential, $V\left(r_{i j}\right)=$ $\left(q_{i} q_{j}=j_{i} \quad r_{j}\right\rangle \exp \left(\quad j_{i} \quad r_{j} j\right)$. Here $q_{i}$ is the charge on colloid $i, 1=$ is the screening length, and $r_{i(j)}$ is the position of particle $i(j)$. The system size is $m$ easured in units of the lattioe constant $a$, which is set to $a=a_{0}$ for m ost of this work, giving a particle density $=1=\mathrm{a}_{0}^{2}$. We take the screening length $=3=a_{0}$. O ur system is periodic in both the x and y directions. T he total num ber of particles is $N=N_{A}+N_{B}+N_{D}$, w ith $N_{A}$ colloids of passive species $A$ and charge $q_{A}$, and $N_{B}$ colloids of passive species $B$ and charge $q_{B} . W$ e add $N_{D}$ active colloids

F IG .1. (a) Velocity v vspow er-law exponent from Eq. 2 for $f_{1}=1: 0$. R atcheting in the positive direction ( $v>0$ ) occurs for $>1$. From top left to bottom left, $f_{2}=f_{1}=1: 0$ ( at line), $0.9,0.8,0.7,0.6$, and $0: 5$. (b) $v$ vs for xed $f_{1}=f_{2}=0: 5$ and, from bottom to top, ${ }_{2}={ }_{1}=3: 25,2.5,2$, $1.5,125$, and 1 .
$w$ ith charge $q$ that respond to an applied ac drive. For the results presented here, we $x \notin=Q_{B}=1=2 . W$ e have also considered other ratios, including the crystalline case $w$ hen $q_{A}=q_{B}=1$. To initialize the system, we start at a high tem perature and anneal either to $T=0$ or to a
xed $T>0$. Thebinary particles ofspecies $A$ and $B$ form a disordered assem bly, w th the active colloids scattered random ly throughout. A fter annealing, we apply a tw ostep ac drive during a single cycle of period. The rst stage is a fast drive w here a constant force off $f_{1}$ is applied for a time $l_{1}$ in the positive $x$-direction. The second stage is a slow drive where a force $f_{2}<f_{1}$ is applied for a time $2^{>} 1_{1}$ in the negative $x$-direction. The ac drive has the properties $f_{1} 1=f_{2}$, with $=1_{1}+{ }_{2}$,so that the particle experiences zero average force during a single cycle. T he average drift velocity $\mathrm{v}_{\mathrm{d}}$ can be obtained after $m$ any cycles. $W$ e conduct a series of sim ulations for di erent particle densities, system sizes, tem peratures, O , ac am plitudes, frequencies, and $\mathrm{N}_{\mathrm{D}}$.

W e rst consider a sim ple $m$ odel that predicts that a ratchete ect can arise in such a system. Recently it was show $n$ theoretically and in sim ulations that, for a single colloid driven with a dc drive through a glassy assem bly of other colloids [14], the colloid velocity follow s a power law V / f w ith = 1:5 for certain param eters. $T$ he power law appears in regim es where the driven colloid produces collective disturbances of the surrounding colloids on length scales of the order of a, the lattioe constant. W hen the density of the surrounding colloids is low, these collective distortions are lost and the velocity of the driven colloid is linear w ith the drive. Linear behavior also occurs when the charge $o$ of the driven particle is much sm aller than that of the surrounding particles. Recent experim ents on driven $m$ agnetic colloids have also found power law velocity-force relations for the driven colloid w ith exponents $=1: 5$ or higher in system $s$ w ith high density [12]. In low density system $s$, the velocity is linear w ith drive.

We nd that for a group of driven particles in a glassy $m$ edia, the velocity-force curve is also of a pow er law

F IG .2. Sim ulation im age. B lack circles: active particles that respond to the ac drive. O pen circles: passive particles form ing the glassy background. Here, $N_{D}=\mathrm{N}=0: 016$.
form. In a system w ith a power law velocity-force relationship, ratcheting can occur under the application of an asymmetric ac drive. D uring a single cycle the colloids $m$ ove a distance $x=f_{1} 1 \quad f_{2} \quad 2$. The net drift velocity is then $v_{d}=x=\left(1_{1}+2\right)$. U sing the condition $f_{1} 1_{1}=f_{2} 2$ the drift velocity can be expressed as

$$
\begin{equation*}
v_{d}=\frac{f_{1} f_{2} f_{2} f_{1}}{f_{2}+f_{1}} \tag{2}
\end{equation*}
$$

If $=1$, as in the case of a single overdam ped particle, then $v_{d}=0$, as expected. For any value of $>1$, how ever, the drift velocity w ill be positive, $\mathrm{v}_{\mathrm{d}}>0$. R atcheting can still occur if $f_{1}$ is close to $f_{2}$ as long as $>1$. Thism odelpredicts that the ratchete ect becom esm ore e cient for larger values of . In $F$ ig. 1 (a) we plot $v_{d}$ vs from Eq. (2), w ith $f_{1}=1$ and ratios of $f_{2}=f_{1}=0: 5$ to 1. For $f_{2}=f_{1}=1, v_{d}=0$ for all, as expected. For $f_{2}<f_{1}$ and $>1$, ratcheting in the positive direction ( $\mathrm{v}_{\mathrm{d}}>0$ ) occurs. $\mathrm{v}_{\mathrm{d}}$ increases w ith larger and larger $f_{2}=f_{1}$. The velocity reverses for $<1$. This is an unphysical lim it for the colloid system, where the low est possible value is $=1$. H ow ever, som e physical system $s$ such as non-N ew tonian uids could have < 1 .

Since the velocity becom es linear w ith the drive at low densities or high drives, it should be possible to select ac drive param eters that reverse the ratchet e ect and give current reversals for $>1$. This can be achieved by setting $1<2$, where the inequality is not too large. In the highly nonlinear regim e the particle $w$ ill still ratchet in the positive direction; how ever, upon approaching the linear regim $e$, the particle $w$ ill ratchet in the negative direction. In $F i g .1$ (b) we show v vs from Eqn. (2) for $f_{2}=f_{1}=0: 5$ and increasing ${ }_{2}={ }_{1}$, where a crossover from a positive to negative ratchet e ect occurs at $c$. Here c increases w ith increasing $2=1$.
W e next consider sim ulation results. In $F$ ig. 2 we show a realspace im age of the sim ulated system with $\mathrm{N}_{\mathrm{D}}=11$

FIG.3. P article velocity v vs tim e $t=$. D otted line: v for an isolated overdam ped particle under an asym $m$ etric ac drive w ith $\mathrm{f}_{1}=0: 56, \mathrm{f}_{2}=\mathrm{f}_{1}=0: 25$, and ${ }_{1}={ }_{2}=0: 25$. Solid line: v in a system of interacting particles. Inset: D rift velocity $\mathrm{v}_{\mathrm{d}} \mathrm{vs}$ $t=$ for (dotted line) a single overdam ped particle, and (solid line) the interacting particle system.
active particles (black circles) and $\mathrm{N}_{\mathrm{A}}+\mathrm{N}_{\mathrm{B}}=678$ pas sive particles (open circles) after $m$ any cycles of the ac drive. The active particles, which were originally scattered throughout the system, have chistered into a lane, and they also drift over tim $e$ in the positive $x$-direction.

In F ig. 3 we plot the velocity vs tim e of a single overdam ped colloid in the absence of any other particles (dashed curve), show ing short large positive pulses and long sm all negative pulses of velocity. H ere we consider the case of $f_{2}=f_{1}=0: 25 \mathrm{w}$ ith $f_{1}=0: 56$. T he average velocity of the isolated colloid is zero in a single period. T he solid line show s the velocity of a driven colloid in the interacting particle system w ith $\mathrm{N}=370$ and $\mathrm{N}_{\mathrm{D}}=11$, in a regim ew here the dc velocity-force curves have a pow erlaw form. H ere, the $m$ agnitude of the particle velocity $v$ during both the positive and the negative portions of the ac drive cycle is sm aller than that of the single particle, and shows considerable uctuations. The integrated velocity during the positive portion of the ac cycle is on average larger in $m$ agnitude than the integrated velocity during the negative portion of the cycle. To show this $m$ ore clearly, in the inset of $F$ ig. 3 we plot the tim eaveraged drift velocity $\mathrm{v}_{\mathrm{d}}$ for each system over m any ac cycles. For the single particle case (low er dashed curve), $\mathrm{v}_{\mathrm{d}}=0$, while for the interacting particle system, $\mathrm{v}_{\mathrm{d}}>0$, w th an long tim e average drift velocity of $\left\langle\mathrm{v}_{\mathrm{d}}\right\rangle 0: 03$, indicating that a positive ratchet e ect is occurring.

W e next consider the dependence of the ratchet e ect on various system param eters. In Fig. 4 (a) we plot the drift velocity $\mathrm{v}_{\mathrm{d}}$ vs the fraction ofdriven particles, $\mathrm{N}_{\mathrm{D}}=\mathrm{N}$, for xed acdrive param eters $f_{1}=0: 56, f_{2}=f_{1}=0: 25$, and ${ }_{1}={ }_{2}=0: 25, w$ ith $a=a_{0}=1 . v_{d}$ goes through $a$
 w ith $\mathrm{f}_{1}{ }_{1}=\mathrm{f}_{2} 2$ and $f_{2}=\mathrm{f}_{1}=0.25$. (a) $\mathrm{v}_{\mathrm{d}}$ vs the fraction of driven particles $N_{D}=\mathrm{N}$ for a density of $=1=a_{0}^{2}$. (b) $v_{d}$ vs particle density for $x e d N_{D}=N=0: 03$. (c) $v_{d} v s$ tem perature $T=T_{m}$ for $=1=a_{0}^{2}$ and $N_{D}=N=0: 03$. ( $d-e$ ) $R$ atchet reversals for a system w ith $f_{1}{ }_{1}=f_{2} \quad 2=0: 9$ : (d) $v_{d}$ vs density . (e) $\mathrm{v}_{\mathrm{d}}$ vs tem perature $\mathrm{T}=\mathrm{T}_{\mathrm{m}}$ for $=1: 26=\mathrm{a}_{0}^{2}$.
$m$ axim um near $N_{D}=N=0: 03$, and then slow ly fallso for higher $N_{D}=N$ before reaching $v_{d}=0$ just below $N_{D}=N=$ 1:0. We have also considered di erent system sizes by varying $a=a_{0}$. We obtain the sam e behaviors, indicating that the ratcheting is not a nite sizee ect. It is sim ple to understand why $v_{d}!0$ in the $\lim$ it of $N_{D}=\mathrm{N}$ ! 1 , since here all the particles $m$ ove in unison $w$ ith the ac drive, and the plasticity responsible for the nonlinear velocityforoe response is lost. For a single driven particle $\mathrm{N}_{\mathrm{D}}=$ 1, we found a dc velocity-force scaling exponent of $=$ $1: 5$. A s the num ber of driven particles $N_{D}$ increases, increasesto $=2$ near $N_{D}=\mathrm{N}=0: 03$, and then decreases back tow ard $=1$ as $N_{D}=\mathrm{N}$ increases further. This result is consistent $w$ th the predictions of Eq. 2 , where a larger ratcheting e ect is expected for larger exponents

In Fig. 4 (b) we consider a system with $\quad$ xed $N_{D}=N=$ $0: 03$ and ac drive param eters, and plot $v_{d}$ vs the system density $m$ easured in units of $1=a_{0}^{2}$. For low densities
< 0:5, the active particles interact only weakly w ith the passive particle background, and the dc velocity-force
curves are close to linear ( 1) so little ratcheting occurs. For large densities $>1: 3$, the ratcheting driff velocity $v_{d}$ decreases since it becom es $m$ ore di cult for the active particles to pass the passive particles. W e have also xed the system density and varied the charge F of the active particles. The behavior is sim ilar to Fig. 4 (b): the ratchet e ect is lost at small 9 f when the velocity-force curve becom es linear. In Fig. 4 (c) we show the e ect of a nonzero tem perature on the ratchet e ect. Weplot va vs $T=T_{m}$, where $T_{m}$ is de ned as the tem perature at which a com pletely ordered single-species colloid assembly w th charge of and density $=1=\mathrm{a}_{0}^{2}$ $m$ elts. For high $T$, the velocity increases linearly w ith force, so the ratchet e ect is lost.

Equation 2 predicts that a reverse ratchete ect should occur for $<1$, as show $n$ in $F$ ig. 1 (a), or for $f_{1} f_{2}$. The reverse ratchet e ect can occur in system $s$ where the $m$ edia responds easily to slow $m$ oving particles but becom es sti er under faster perturbations. For exam ple, in granular $m$ edia the grains respond in a uid $m$ anner to a slow m oving ob ject, while for a fast $m$ oving ob ject the granular $m$ aterial jam s and acts like a solid. M any polym er system s show a sim ilar response. In order for a ratchet e ect to occur in a substrate-free system, there $m$ ust be a com bination of the nonlinear behavior of the particle $m$ otion and the left-right sym $m$ etry breaking by the ac drive. In general the ratchet e ect we observe should occur for any $m$ edia that has a nonlinear viscosityfrequency response.

In Fig. 4 (d,e) we consider two cases where ux reversals occurw th $f_{1} 1_{1}=f_{2}=0: 9$. For the param eters chosen here, the drift velocity of an isolated particle would be $v_{d}=0: 016$. In $F$ ig. 4 (d) we plot $v_{d}$ vs density for $N_{D}=\mathrm{N}=0: 03$. For low density $<0: 3$, the velocity-force response curve is linear ( = 1) and the particle m oves in the negative direction as expected for this ac drive. As the density increases, the velocity-force response curve becom es nonlinear, and $v_{d}$ crosses over to a positive value $v_{d}>0$ as the ratcheting e ect reaches a maxim um near
$=1=a_{0}^{2}$. The drift velocity drops at high density just as in $F$ ig. 4 (b). In $F$ ig. 4 (e) we show $V$ vs $T=T_{m}$ for the sam e system w ith a xed density of $=1: 26=\sigma_{6}^{2}$. For low tem peratures, the velocity-force response curve is nonlinear, and a ratchet e ect $w$ ith positive velocity occurs. A s the tem perature increases, the drift velocity $v_{d}$ drops and crosses back to a negative value as the system enters the linear response regim $e . v_{d}$ saturates to $v_{d} \quad 0: 01$, slightly sm aller in $m$ agnitude than the value expected for a single isolated particle. W e have also considered the ect ofchanging $G$ at xed density and $T=0$, and observe behavior sim ilar to that show $n$ in $F$ ig. 4 (d).

In conclusion we have investigated a \glassy ratchet" e ect, which occurs in a glassy system of interacting particles w ithout a quenched substrate. W e considered the speci c case of a disordered assem bly of colloids with overdam ped dynam icsw here only one colloid species cou-
ples to an ac drive. The ac drive is asym $m$ etric, with a large positive drive applied for a short tim e followed by a sm all negative drive applied for a longer tim e, and obeys the constraint that the net applied force on the driven colloids is zero in a single cycle. A ratchet e ect occurs when the driven and the non-driven colloids are coupled, producing a nonlinear velocity-force response. $\mathrm{W} e$ nd that the dc drift velocity has a maxim um value as a function of the fraction ofdriven particles, tem perature, and particle density. A sim plem odelfor the ratchet e ect agrees well w th our sim ulation results, including the occurrence of ratchet reversal regim es. T he system considered here can be realized experim entally for magnetic or charged colloids driven through non-m agnetic or uncharged colloids. O ur results $m$ ay also have applications for new types of electrophoresis devices.
