(D ated: M arch 22, 2024)

Quasi-particle spin susceptibility (^{qp}) for various heavy-ferm ion (HF) superconductors are discussed on the basis of the experim ental results of NMR Knight shift (K), NMR relaxation rate $(1=T_1)$, and electronic specic heat ($_{e1}$) within the framework of the Fermi liquid model for a Kramers doublet crystal electric eld (CEF) ground state. is calculated from the enhanced Som m enfeld coe cient $_{e1}$, and $_{T_1}$ from the quasi-particle K orringa relation T_1T (K $_{T_1}$)² = const: via the relation of $T_1 = (N_A B = A_{hf})K_{T_1}$ where A_{hf} is the hyper ne coupling constant, N_A the Abogadoro's number and $_{\rm B}$ the Bohr magneton. For the even-parity (spin-singlet) superconductors $CeCu_2Si_2$, $CeCoIn_5$ and UPd_2Ai_2 , the fractional decrease in the Knight shift, $K^{obs} = K^{obs}(T_c) - K^{obs}(T_c)$, below the superconducting transition temperature (T_c) is due to the decrease of the spin susceptibility of heavy quasi-particle estim ated consistently from and $_{\text{T}_1}$. This result allows us to conclude that the heavy quasi-particles form the spin-singlet C opper pairs in $C \in Cu_2 Si_2$, $C \in CoIn_5$ and UPd_2Al_2 . On the other hand, no reduction in the Knight shift is observed in UP t₃ and UN i₂A l_3 , nevertheless the estimated values of l_1 and l_1 are large enough to be probed experimentally. The odd-parity superconductivity is therefore concluded in these com pounds. The NMR K night shift result provides a convincing way to classify the HF superconductors

into either even-or odd-parity pairing.

I. IN TRODUCTION

Extensive experimental and theoretical works for heavy-ferm ion (HF) systems have uncovered characteristic feature that a localized f state at high temperatures crosses over to a delocalized HF one at low tem peratures through the hybridization with conduction electrons. This occurs below a so-called coherent Kondo tem perature T_K , being compatible with a renormalized heavy quasi-particle band width, leading to rich em ergent phenom ena such as either even-or odd-parity unconventional HF superconductivity (SC), anom alous m agnetic or multiple ordering, etc. It has been con med that most physical quantities are described in terms of the Ferm i-liquid theory,¹ e.g. revealing the enhanced Pauli m agnetic susceptibility ((T) ' (0)), the tem perature _{el}T) where (T)-linear coe cient in speci c heat (C = el is the enhanced Som merfeld coe cient, the T-square behavior in resistivity $(=_0 + AT^2)$, etc.

As listed in Table I, the HF SC has been found in cerium (Ce) and uranium (U) based HF compounds, such as $CeCu_2Si_2$,² $CeIrIn_5$,³, $CeCoIn_5$,⁴, UBe_{13} ,^{5,6} UPt₃,^{7,8,9} URu₂Si₂,^{10,11,12} UNi₂Al₃,^{13,14} UPd₂Al₃,^{15,16,17} at am bient pressure. In these heavy-ferm ion superconductors

(HFS's), both large $_{\rm el}$ value and specic heat jump, C=C $_{\rm el}(T_{\rm c})$ ' 1, associated with the superconducting transition give unambiguous evidence that the heavy quasi-particle itself takes part in the formation of the C ooper pairs.

In recent years, an intim ate interplay between antiferrom agnetism (AFM) and SC has been the most interesting and outstanding issue in Cebased HF systems. It is believed that the SC in $CeCu_2Si_2$,² $CeIrIn_5$,³ and $CeCoIn_5^4$ emerges at the border of AFM even at ambient pressure (P = 0). The nding of pressure-induced SC in $CeCu_2Ge_2$,¹⁸ $CePd_2Si_2$,¹⁹ $CeIn_3$,²⁰ and $CeRhIn_5^{21}$ strongly suggest that AFM and SC are related to each other because P-induced SC occurs either when AFM vanishes or coexists with it.²²

It is wellknown that K night-shift measurements played vital role for establishing the Bardeen-Cooper-Schriefer (BCS) theory for spin-singlet s-wave superconductors,³⁷ and are the most powerful tool to identify which odd-or even-parity Cooper pairing state is realized in superconductors. When the system undergoes a superconducting transition, the spin susceptibility $_{\rm S}$ does decrease to zero at T = 0 below T_c for even-parity (spin-singlet) supercon-

ductors as follow s:

$$_{\rm s} = 2 {}^{2}_{\rm B} N_{0} Y (T);$$
 (1)

where Y (T) is the Yosida function de ned by 38

$$Y (T) = \frac{2}{N_0} \sum_{0}^{Z_1} N_{BCS} (") \frac{df (")}{d"} d"; \qquad (2)$$

and N $_0$ is the density of states (DOS) at the Ferm i level in the norm al state, N $_{\rm BCS}$ (") is the DOS in the BCS superconducting state, and f (") is the Ferm i-D irac function.

In transition m etals and alloys, the electronic state is form ed as follows. The crystal electric eld (CEF) splitting is much larger than the energy scale of the intraatom ic spin-orbit coupling (SOC), the orbital part of susceptibility arises from the second order interband m ixing e ect with other bands, giving rise to T independent Van V leck susceptibility. A coordingly, only its spin part yields the T dependence of susceptibility. Since both the K night shift (K) and the susceptibility () depend on T, the contributions from the spin and the orbital parts are decom posed by taking the C logston-Jaccarino plot of K (T) vs. (T) with T as an implicit param eter.³⁶ In the superconducting state, the spin part of the susceptibility decreases to zero in accordance with eqs. (1) and (2).

On the other hand, the f-electron systems with the strong SOC are generally described by a total angular momentum, J = L + S. Furthermore, the CEF splits the lowest J manifold into several doublets and/or singlets. If the simple localized f electron picture can be applied for HF systems, the classicalVan V leck susceptibility between the lowest lying CEF level forming quasi-particle bands and other CEF levels are given by

$$v_{V} = 2N_{A} \frac{g_{J}^{2} g_{B}^{2}}{Z} \frac{X}{E} \frac{\text{h } jJ_{i} \text{ j } i\hat{j}}{E}; \qquad (3)$$

where N_A the Abogadoro's number, g_J the Lande factor, _B the Bohrm agneton, Z the distribution function. E and E are ground () and excited () state energies. Note that this interband contribution reveals a T dependence when the CEF splitting is compatible with T. That is, the T dependence of both K and are not due to real spin, but to ctitious spin including the interband contributions. Therefore, it is di cult to conclude the odd-parity superconducting state in case of the Van V leck contribution being dom inant,^{39,40,41} even though K unchanges across T_c . Anyway, in the HF systems, it is not so clear to extract the quasi-particle spin susceptibility ^{qP} via the C logston-Jaccarino plot, and it is crucially in portant to recon rm the ^{qP} due to heavy quasi-particles.

In this paper, we show that the quasi-particle spin susceptibility $^{\rm qp}$ in HFS's is reasonably estimated from the NMR and specic heat results on the basis of the Ferm iliquid theory with a K ram ers doublet CEF ground state.¹ In x 2, we remark that $^{\rm qp}$ is independently estimated

from the Sommerfeld coe cient $_{\rm el}$ and the NMR relaxation rate $1=T_1$, which are consistent with qp estimated from the Clogston-Jaccarino plot. In x 3, we describe the basic assumptions for the present analysis. Section 4 is devoted to the analysis of the experim ental data for various HFS's in terms of the Ferm i-liquid model. We also discuss the validity of the present model. A fter the brief com m ents on the quasi-particle susceptibility in the superconducting state in x 5, we discuss the relation between the Knight shift and the parity of the order param eter (OP) in the superconducting state in x 6. From these analyses, $C \in C u_2 S i_2$, $U P d_2 A i_3$, and $C \in C o In_5$ are reinforced to be an even-parity (spin-singlet) superconductor, whereas UPt₃ and UN i₂A l₃ are recon m ed to be an odd-parity (spin-triplet) superconductor. Finally, x 7 is devoted to several concluding remarks.

II. NMR PARAMETERS AND THEIR RELATION TO FERM I-LIQUID PARAMETERS

A. Quasi-particle susceptibility

In the Ferm i-liquid theory for HF system, the electronic speci c-heat coe cient $_{\rm el}$ (in units permole) and the quasi-particle spin susceptibility $^{\rm qp}$ (in units permole) are enhanced by the mass enhancement factor ~, and the magnetic enhancement factor ~ $_0$ associated with the contribution of f-electrons to the spin susceptibility, respectively. These are approximately written as¹

el '
$$\frac{2}{3}N_{\rm A} \,^{2}k_{\rm B}^{2\,\rm f}$$
 ("_F)~; (4)

^{qp}
$$\prime = \frac{2}{3} N_A g_J^2 J_{eff}^2 B_B^2 f("_F) \sim_0;$$
 (5)

where k_B is the Boltzm ann factor, J_{eff} the electrons spin, f ("_F) the one-spin DOS at the Ferm i level for bare felectrons. Here, the DOS per spin of quasi-particles is approximately written by

$$("_{\rm F})' \stackrel{f}{=} ("_{\rm F}) \sim :$$
 (6)

From eqs. (4) (6), $^{\rm qp}$ is related to $_{\rm el}$ as

$${}^{\rm qp} = \frac{2}{3} N_{\rm A} g_J^2 J_{\rm eff}^2 {}_{\rm B}^2 ("_{\rm F}) \frac{\sim_0}{\sim}$$
$$= \frac{{}_{\rm el} g_J^2 J_{\rm eff}^2 {}_{\rm B}^2}{{}^2 k_{\rm B}^2} R; \qquad (7)$$

where R is the so-called W ilson Ratio, de ned by R $\sim_0=\sim$.

W hen an external magnetic eld is applied, $^{\rm qp}$ produces a small additional magnetic eld at the nucleus. This gives rise to a K night shift (K $^{\rm qp}$) due to the quasiparticles that is scaled to $^{\rm qp}$ through the hyper necoupling constant A_{hf} (in units per _B) at q = 0 as

$$K^{qp} = \frac{A_{hf}}{N_{A-B}} qp :$$

TABLE I: Physical quantities and NMR parameters for various HFS's. T_K , $_{el}$, T_c , A_{hf}^i , and $(1=T_1T)_{T_c;i}$ are C oherent K ondo tem perature, Som m erfeld coe cient (at T_c), superconducting transition tem perature, hyper ne coupling constant, NMR spinlattice relaxation rate divided by tem perature at T_c , respectively. Here i = k;? (see text).

[1] from Refs.^{2,23,24,55} [2] from Refs.^{5,6,34} [3] from Refs.^{7,8,9,31,32,57,58} [4] from Refs.^{10,11,12,35} [5] from Refs.^{13,17,27,28,29} [6] from Refs.^{14,15,33} [7] from Refs.^{4,25,26} [8] from Refs.^{69,70,71} [9] taken from the metallic behavior in resistivity (Refs.⁶⁹)

From eqs. (7) and (8), we obtain the quasi-particle spin contribution to the K night shift, K $^{\rm qp}$, as

$$K^{qp} = \frac{A_{hf}}{N_{A-B}} \frac{elg_J^2 J_{eff-B}^2}{^2k_B^2} R:$$
(9)

Here it is noteworthy that no interband contributions are included in this form ula.

B. Quasi-particle K orringa relation for isotropic system

The nuclear spin-lattice relaxation process basically occurs through the spin- ip process between the state j 1=2i and j+ 1=2i of conduction electrons. Provided that HF state is realized at low temperatures below $T_{\rm K}$, K $^{\rm QP}$ is also extracted using the NMR relaxation rate, $1=T_1$.

In general, $1=T_1$ is given by 4^7

$$\frac{1}{T_{1}} = \frac{2 {}_{N}^{2} k_{B} T}{(g_{J} {}_{B})^{2}} \lim_{! {}_{0}} X_{I} f_{hf}(q) \int_{1}^{2} \frac{\text{Im}_{?}(q;!)}{!}; \quad (10)$$

where $_{\rm N}$ is the nuclear gyrom agnetic ratio, $A_{\rm hf}(q)$ the q-dependent hyper ne-coupling constant and Im $_2$ (q;!) the imaginary part of the transverse component of dynamical susceptibility (q;!) of quasi-particles. If the HF state is formed above T_c, the imaginary part of (q;!) is expressed within the random phase approximation (RPA) as,^{1,48}

Im
$$(q;!)' \sim (q;!)^2$$
 Im $_0^{t} (q;!);$ (11)

where $\int_{0}^{f} (q;!)$ is the dynamical susceptibility of felectrons and $\sim (q;!)$ an enhancement factor due to the electron-electron interaction as

~
$$(q;!)$$
 $\frac{(q;!)}{\int_{0}^{f} (q;!)}$: (12)

Since the in aginary part of ${}_{0}^{f}$ (q;!) near at the Ferm i level "_F is expressed as^{48,49}

$$\operatorname{Im} \ {}_{0}^{f}(\mathbf{q}; !) = \frac{2}{3} \ {}_{3}^{2} \ {}_{B}^{2} \ {}_{deff}^{2} ! \\ {}_{k} \ {}_{k} \ {}_{deff}^{f}(\mathbf{m}) \qquad (! \ {}_{k+q}^{f} + {}_{k}^{f});$$
(13)

then we have

$$\lim_{\substack{l \neq 0 \\ q}} \frac{X}{q} \frac{\text{Im}(q; l)}{l} = \frac{2}{3} q_{J}^{2} g_{B}^{2} J_{eff}^{2} f(\mathbf{T}_{F})^{2} \qquad X \sim_{q}^{2} ;$$
(14)

where $\sim_q \sim (q; ! ! 0)$ at the NMR frequency and the bracket represents averaging over the Ferm isurface. If we are neglect the q dependence of the hyper ne coupling, then $A_{\rm hf}(q)$ is replaced by $A_{\rm hf}$ and the NMR relaxation rate $1=T_1$ is expressed as

$$\frac{1}{T_{1}} = \frac{4}{3 h} (_{N} hA_{hf})^{2} (g_{J} J_{eff})^{2 f} ("_{F})^{2} k_{B} T \bigvee_{q}^{2} \gamma_{q}^{2};$$
(15)

From eqs. (5), (8) and (15), we have

$$\frac{1}{T_{1}T} = \frac{3k_{B}}{h} - \frac{N}{g_{J}} \frac{M}{J_{eff}} B^{2} (K^{qp})^{2} K ()$$
(16)

 $D_P \xrightarrow{E}_{q \sim q^2} = \sim_0^2$ is the enhancement facwhere K () tor and is the parameter associated with the Stomer factor.⁵¹ If the enhancement factor $\frac{1}{q} \sim_q^2$ is the same as that at q = 0, i.e, K () = 1, this relation is similar to the so-called Korringa law. Then, when ferrom agnetic and antiferrom agnetic spin uctuations becom e dom inant due to electron-electron correlation e ect, K () < 1 and K () > 1 are expected, respectively. Here we should notice that 1=T1 does not include any interband contributions associated with the excitations across the CEF splitting. This is because $1=T_1$ involves the imaginary part of the dynamical susceptibility in the low energy limit as !! 0, as seen from eqs. (10) and (14). Anyway, K $^{\rm qp}$ derived from the quasi-particle K orringa relation does indeed give the quasi-particle susceptibility.

III. BASIC ASSUMPTIONS FOR ANALYSIS

A. CEF ground state

In Table I, we notice that the NMR $1=T_1$ for HFS's is enhanced by more than ten times in comparison with that for non-HF m aterials, 23, 25, 27, 28, 29, 33, 34, 35, 56, 57, 58 for instance $1=T_1T = 33 (1/sK)$ for ¹⁹⁵ Ptofpure Ptm etal⁵⁹, and $1=T_1T = 0.033$ (1/sK) for ²⁷Al for LaP d₂A l₃,⁶⁰ etc. This means that the heavy quasi-particles are involved in the NMR relaxation process. Since the non-K ram ers ground state is magnetically intact, it is di cult to explain the enhanced relaxation rates observed in HFS's by the present Ferm i-liquid m odel. A sm entioned in the previous section, the spin- ip process of conduction electrons would not occur through the Van V leck type inter-band excitations in the low-energy lim it as ! ! 0. Thus, we assum e that the enhanced relaxation rate is ascribed to the m agnetically degenerated HF ground state. Nam ely, we assume that several doublets and singlets lying in lower energy region than $k_B T_K$ are renorm alized into a ground state having K ram ers degeneracy via the c f m ixing e ect.

B. E ective m om ent below $T_{\mbox{\scriptsize K}}$

In the spherical system without any CEF, the e ective spin is de ned as $J_{pff}^2 = J(J + 1)$ and the e ective moment is $p_{eff}^{eff} = g_J J(J + 1)_B$. For the free electrons, $J_{eff} = 3=2$ and $_{eff} = 1:73_B$. In HFS's, the CEF level scheme, that is determined experimentally, should be taken into account. Furthermore, several doublets and singlets are expected to be renormalized by the c f mixing e ect in the heavy-Femi-liquid state. It is, however, underlying issue to estimate to what extent the CEF level splitting a ects P in HFS's.

For Ce-based HFS's having the clear CEF level splitting, the basis function of a CEF ground state is not spherical but anisotropic. In order to introduce the anisotropy, we assume that the e ective m om ent at low T's is attributed to only the CEF ground state level and we do not take the average of each direction. Then, the e ective m om ent is tentatively replaced by $i_{eff}^{i} = g_J J_{eff}^{i} B = g_J h 0 j J_j j 0 i_B$ where j0 is the basis function of a CEF ground state. For CeCu₂Si₂, using the CEF scheme,⁵⁵ the respective e ective m om ents at low T for H ? c and H k c are estimated as $e_{eff}^{?} = g_J B h 0 j J_2 j 1 i 0.90 B and eff = g_J B h 0 j J_k j 1 i 1.07 B. For CeC oIn₅,²⁶ the e ective m om ent for H ? c is also calculated as <math>e_{eff}^{?} = 1.28 B.$

By contrast, for U-based system s, a clear CEF level splitting has not been reported yet. This has been generally accepted as the itinerant nature of U 5f-electrons. So that, the basis function would be rather spherical. In our analysis, the e ective moment for U-based system s is tentatively taken as $_{\rm eff}$ = 1:73 $_{\rm B}$, i.e., free electron value. The magnetic anisotropy is, how ever, expected from the various magnetic measurements. Therefore the e ective moment for the magnetically easy axis is taken to be $_{\rm eff}^{\rm easy}$ = 1:73 $_{\rm B}$, while that for the magnetically hard axis is to be $_{\rm eff}^{\rm hard}$ = 1:73 $_{\rm B}$ $_{\rm hard}^{\rm obs}$ = $_{\rm easy}^{\rm obs}$, is estimated from the anisotropy in magnetic susceptibility at T_c listed in Table I.

C. Hyper ne coupling constant

The q-dependent hyper ne coupling constant $A_{hf}(q)$ in eq. (10) is the spatial Fourier transform of the hyper ne coupling $A_{hf}(r)$ between nucleus and Ce/U ions separated a distance r. If the nucleus is coupled to only one Ce/U ion, $A_{hf}(q)$ is independent of q. In the HFS's, the calculation of $A_{hf}(q)$ would require one to sum over contributions from the next nearest Ce/U neighbors. How ever, $A_{hf}(r)$ is not so sim ple. Therefore, under the m ost naive assumption, we neglect the wave num ber dependence of the hyper ne coupling constant, i.e., $A_{hf}(q) = A_{hf}$.

D. A nisotropic quasi-particle K orringa relation

In HF systems, the magnetic anisotropy is inevitable even in the HF state because the HF state at low T is formed through the c f hybridization. It should be noted that a large magnetic anisotropy in ${}^{\rm qp}_{i}$ (i = a;b;caxes) arises from the anisotropy in the hyper ne-coupling constant ($A^{i}_{\rm hf}$), the e ective moment (${}^{i}_{\rm eff}$) and the enhancement factor (${}^{-i}_{0}$). Unfortunately, no anisotropic Ferm i liquid theory have been provided yet. Furthermore, the CEF splitting and the c f mixing e ect are not so clear in quantitative level. Therefore, from a phenomenological point of view, a uniaxial magnetic anisotropy is taken into consideration as

$${}^{\rm qp}_{\rm i} = \frac{2}{3} N_{\rm A} {}^{\rm i}_{\rm eff} {}^{2} {}^{\rm f} ("_{\rm F}) \sim {}^{\rm i}_{0}; \qquad (17)$$

where i = k, and ? which mean the respective parallel and perpendicular components to the eld direction, e.g., k = c and ? = a = b. Then the Knight shift in eq. (8) or (9) is replaced by anisotropic K night shift as

$$K_{i}^{qp} = \frac{A_{hf}^{i}}{N_{AB}}_{i}^{qp}$$

$$= \frac{A_{hf}^{i}}{N_{A} B} \frac{el(\frac{i}{eff})^{2}}{2k_{B}^{2}} R_{i}: \qquad (18)$$

The quasi-particle K orringa relation, eq. (16), is modied using an isotropic parameters, A_{hf}^{i} , e_{ff}^{i} , and K_{i} (), as

$$\frac{1}{T_1 T} = \frac{3 k_B}{h} - \frac{N h}{\frac{2}{eff}} (K_2^{qp})^2 K_2 ();$$
(19)

and

$$\frac{1}{T_{1}T} = \frac{3 k_{B}}{2h} : \frac{N h}{\frac{2}{eff}} (K_{2}^{qp})^{2} K_{2} () + \frac{N h}{\frac{k}{eff}} (K_{k}^{qp})^{2} K_{k} ();$$
(20)

IV. DISCUSSION : THE NORMAL STATE

A. Quasi-particle K orringa relation

W ith above assumptions, we calculated the elective values of the quasi-particle K night shifts at T_c from eqs. (18) (20) by using parameters $_{el}$, A_{hf}^i , and $(1=T_1T)_{T_c,i}$ listed in Table I. Here we dened the elective quasi-particle K night shift associated with $_{el}$ including the W ilson ratio R as K $_{i}$ $K_i^{qp} = R_i$ while that associated with T_1 including the enhancement factor K i () as K $_{T_1,i}$ $K_i^{qp} = K_i$ (). Thus calculated values K $_{i}$ and K $_{T_1,i}$ for various HFS's are listed in Table II.

As clearly seen in the eqs. (18) = (20), both \sharp ;ijand $\sharp_{T_1,i}$ jdepend on the size of $_{eff}$. In order to check the validity of the present analysis, $\sharp_{T_1,i}j($ $\sharp_i^{qp}j$ $\overline{K_i()})$ is plotted against \sharp ;ij ($\sharp_i^{qp}j$ \mathbb{R}_{T_c}) for various HFS's in Fig. 1. M ost of values are consistent with a relation of $\sharp_{T_1,i}=K_{,i}j=R_{T_c}$ $\overline{K_i()}=1$ except CeC u_2 Si₂ and CeCoIn₅.

A coording to the Ferm i-liquid theory,^{1,43} the W ilson ratio varies in the range of 1R 2. Sim ply, R = 1 is the lim it of electron-electron correlation parameter U ! 0, while R = 2 is the lim it of U ! 1 . The recent theoretical studies have predicted that the mass enhancement factor is comparable to the magnetic one, i.e., the W ilson ratio is R 12^{43,45} A ctually in CeCu₂Si₂, under the present assumption of $_{eff}$ (1 $_B$), we obtain $R_{T_c} = 1.24$ from eq. (7) with the experimental values, $_{e1}$ 1000 m J/(m oleK²),² and $_{obs}$ (T_c) 6 10³ (em u/m ole).⁶¹ A good agreement between the theoret-

ical and the experim ental values strongly suggests the W ilson ratio in the HF liquid state is on the order of unity.

For U-based HFS's, on the other hand, the absence of the clear CEF splitting prevents quantitative estimates for $_{eff}$, consequently for R_{T_c} . However R_{T_c} would be more close to unity than that in Ce-based systems because U-based HFS's share more itinerant nature than Ce-based ones do. Thus the relation of $K_{T_1,i}=K_{ij}$ R_{T_c} K_i () = 1 suggests that eff 1:73 _B is probably a good approximation for the e ective moment in the U-based systems. Instead, if we assume $_{eff} = 1_{B}$ and $R_{T_c} = 1$ in U-based systems, we obtain K_i () 4 that is comparable to that in Ce-based HFS's in which antiferrom agnetic spin uctuations are dom inant and system s are close to a magnetic quantum critical point.^{62,63} This is, however, unlikely to occur in U-based HFS's becasue $1=T_1T = const:$ behavior strongly suggests that antiferrom agnetic spin uctuations are not dom inant at low T's.

To be emphasized here is that the quasi-particle K orringa relation is actually hold in the HFS's, though it is still unclear to evaluate R_{T_c} and $K_i()$ experimentally. We also calculated the susceptibilities $_{ii}(= \frac{qp}{i} = R_i)$ and $_{T_1,i}(= \frac{qp}{i} \frac{K_i()}{K_i()})$ at T_c by using eq. (18) (see Table III).

B. Van Vleck susceptibility

Here we deal with the Van V leck susceptibility $_{VV;i}$. A coording to the theoretical arguments, $^{1,43,44,45}_{VV;i}$ is

TABLE II: Observed reduction of the K night shiff $p = \frac{K^{obs}}{K} = K^{obs} (T_c) + K^{obs} (T_c) = 0$ at T ! = 0 K for various heavy ferm ion superconductors. K $K^{qp} = R_{T_c}$ and $K_{T1} + K^{qp} + \frac{K^{obs}}{K} = K^{obs} (T_c) + K^{obs} (T_c) + 0$ are the calculated elective K night shifts in the norm all state from the electronic specific heat (e_1) and the NMR relaxation rate $(1=T_1)$ assuming $A_{hf}(q) = A_{hf}$, respectively. Here we assume eff $1:73_B$ for U-based HFS's (see x 3). For UPt₃, the respective K obs 's for C and B-phases are listed.

FIG. 1: $K_{T_1} j (= K^{qp} j \overline{K_{i(1)}})$ plotted against $K j (= K^{qp} j R)$ for various HFS's. HETOU, KATSMAK, Yi KIROKST ated from the quasi-particle K orringa relation $(T_1 T (K^{qp})^2 K () = constant)$ and the electronic speci c heat $(K^{qp} / e_1 R)$ just above T_c , respectively. Here we assume A_{hf} (q) = A_{hf} for calculations of K_{T_1} , and e_{ff} 1.73 B for U-based HFS's (for details, see x 3). The solid line shows R $\overline{K()} = 1$.

generally expressed as,

$$v_{V,i} = r_{i} \qquad \stackrel{qp}{i}; \qquad (21)$$

where $T_{r,i}$ is the total susceptibility and $T_{r,i} = \int_{0}^{0} ds (T_c)$ at T_c . As discussed in the previous section, both $T_{r,i}$

om Refs.³⁵ [5]from Refs.^{27,28,29} [6]from Refs.³³ [7]from Refs.²⁵ [8]from Refs.⁷¹

and $T_1 \stackrel{\text{def}}{\to} provide the quasi-particle susceptibility <math>\stackrel{\text{qp}}{i} = R$ and $\underset{i}{\operatorname{qp}P} \overline{K_{i}}$ (). If we assume $R_{T_{c}}$ 1, ^{qp}_i ;i• That is, the Van Vleck susceptibility is approximately ;i.⁶⁶ The calculated valwritten as $v_{V;i}$ ' $_{i}^{obs}$ (T_c) ues of vv_{i} are listed in Table III. Note that $i(T_c)$'s are larger than $_{i}$ and $_{T_1}$; except for UBe₁₃,⁶⁵ and VV:i's are comparable with or larger than the quasiparticle susceptibility. This seems to be consistent with the theoretical prediction that vv can become comparable with or larger than the quasi-particle susceptibility $(^{\text{qp}})$ via c f m ixing^{39,40,41,43,44,45} This in turn indicates the observed Knight shift K obs involves the Van V leck contribution.

V. QUASI-PARTICLE SUSCEPTIBILITY IN THE SUPERCONDUCTING STATE

Here, we discuss about a relation between the K night shift and the parity of the superconducting order param – eter (OP). In the superconducting state, the DOS for quasi-particle excitations is written as^{52}

$$s^{(")} = \frac{d_{k}}{4} \frac{q_{("_{F})} j^{"_{j}} j}{\frac{m^{2}}{2} j(k) j^{2}};$$
$$= \frac{("_{F}) j^{"_{j}} j^{Z_{2}} z}{4} \frac{sin dd}{\frac{m^{2}}{2} j(k) j^{2}}; (22)$$

where the integral is over the solid angle of $_k$ and $~~({}^{\rm \! T}_{\rm F}$) is the quasi-particle D O S at the Ferm i surface in the nor-

m al state de ned by eq. (6). Here (k) is the gap function and is given by

$$(k) / (\dot{q} \frac{(k)j}{jd(k)j^{2}} \frac{(l = even);}{jd(k)j^{2} jd(k) d(k)j(l = odd);}$$
(23)

where (k) is a single even function for a spin-singlet pairing state (S = 0, 1 = even), whereas d = $(d_x; d_y; d_z)$ a d-vector for a spin-triplet pairing state (S = 1, 1 = odd) D ue to the k dependence of the OP, the superconducti energy gap vanishes at points and/or along lines on t Ferm i surface.

The quasi-particle spin susceptibility, ${}^{\rm qp}$, below T_c even-parity superconductors is expressed as,

$$_{i}^{qp} = \frac{2}{3} N_{A} {_{eff}}^{i}^{2} ("_{F}) R_{i} Y (T);$$

(2

and

$$Y (T) = \frac{2}{("_{F})} \int_{0}^{Z_{1}} s (") \frac{df (")}{d"} d":$$

Thus $^{\rm qp}$ decreases down to zero as T ! 0 for the even parity (spin-singlet) superconductors, when the surface and/or impurity e ect are absent. Notice here the the anisotropy of the e ective moment $_{\rm eff}^{\rm i}$ causes the anisotropic decrease of $^{\rm qp}$ below $T_{\rm c}$, depending on a edirection.

Dierently from an even-parity pairing state, an odd-parity pairing state, the Zeem an interaction djdue to the spin of the Cooper pa (1=2) ^{qp}∄ (d-vector) should be taken into consideration. Unla d-vector is locked to the lattice, the application of a m akes the d-vector rotate as d? H so as to m in in ize t Zeem an energy. In this case the quantization axis for t spin of the Cooper pairs is always parallel to the ma netic eld. Namely, the quasi-particle susceptibility is essentially the same as that in the norm al state; does not change below T_c . If the spin of the Coop pairs is frozen " w ith the lattice, 52,53 it is expected ththe quasi-particle susceptibility, qp (I), decreases wh H k d even for an odd-parity pairing state. It has be argued that the strong intra-atom ic SOC may make vector freeze. But, unfortunately, the inter-atom ic SO for the pairs remains quite obscure.⁵⁴

VI. DISCUSSION: THE SUPERCONDUCTING STATE

A. Knight shift and parity of the Cooper pairs

Figure 2 shows the T dependence of the K night shift for $C \in Cu_2 \operatorname{Si}_2$,²³ $C \in Co \operatorname{In}_5$,²⁵ and $U \operatorname{Pd}_2 A \lg \cdot^{27,28}$ Figure 3 shows the T dependence of the K night shift for $U \operatorname{Pt}_3$ (for the C -phase in m ultiple phases)^{31,32}, $U \operatorname{Ni}_2 A \lg \cdot^{33}$, and $\operatorname{Sr}_2 R u O_4$.⁷¹ A s clearly seen in Fig. 2, the reduction of the K night shift below T_c de ned by

$$K^{obs} K^{obs} (T_c) K^{obs} (T ! 0);$$
 (26)

is independent of the crystal direction for $C \, eC \, u_2 \, S \, i_2$, $C \, eC \, o \, In_5$, and $U \, P \, d_2 \, A \, j_2 \cdot ^{23,25,27,28}$ T he fractional decrease in K obs below T_c is ascribed to the reduction of ${}^{\rm qp}$ due to the form ation of the spin-singlet C ooper pairs. In F ig. 3, on the other hand, the $K \, ^{obs}$'s unchange across T_c for $U \, P \, t_3$ and $U \, N \, i_2 \, A \, j_4$, and also for $Sr_2 \, R \, u \, O \, _4 \cdot ^{31,32,33}$

FIG. 2: (a) T dependence of the ⁶³ CH Tothigh (Side S'fKiepka ented powder sample measured by Ueda et al. (Ref.²³). (b) T dependence of the ²⁷ A HK night shifts measured by K yogaku et al. (Refs.^{27,28,29}). C losed triangle shows the K night shift for H ? c in oriented powder sample. C losed and open circles show the respective K night shifts for H ? c and k c in single crystalline sample. (c) T dependence of the ¹¹⁵ In-K night shifts for oriented powder sample measured by K ohori et al. (Ref.²⁵). The solid lines in gures are calculations using the Som m enfeld coe cient el for a d-wave singlet E lg m odel (see x 6.1). Here we assume eff 1:73 B for U-based HFS's (for details, see x 3).

The solid lines in the gures are calculated from eqs. (8), (22), (24), and (25), with the anisotropic energy gap (T;k). In our calculations, we tentatively choose

the gap function as d-wave E_{1q} , $5^{2,67}$

$$(T;k) = (T)(k_x ik_y)k_z$$

$$= (T)sin cos e^{i}$$
(2)

with the T dependence of the gap which is the same a the BCS theory as

(T) = (0)
$$\tanh \frac{k_{\rm B} T_{\rm c}}{(0)} = \frac{C}{C} \frac{T_{\rm c}}{T} = \frac{1}{T};$$
 (28)

where C=C is the specic heat jump, and a = 2, and (0) is the magnitude of the superconducting energy gap. Since the energy gap for the E_{1g} symmetry vanishes along the line on the Fermi surface, i.e $_{\rm s}$ (") / " (" (0)), it can explain the T ³ behavior of NMR Relaxation rate observed in the HFS's, when $1=T_1$ / $_0$ $_{\rm s}$ (")²f (")(1 f ("))d" / T³ for line-nod gapped superconductors. Furthermore, we use K a K ^{qp} assuming R_{Tc} = 1. This is because K_{T1} is sometimes enhanced by K () for R_{Tc} = 1, so that the spi part may be overestimated.

The calculations reproduce the observed fractional de crease in K obs , i.e. K $_{2}^{obs}$ 0:12 % and $K_{L}^{obs} <$ 0 % for CeCu₂Si₂ (⁶³CuNMR)²³; K^{obs} 0:08 0: % for UPd₂AL (²⁷AINMR)^{27,68}; K^{obs} 0:5 0:6 for CeCoIn₅ (115 In NMR).²⁵ Here, the T dependence d calculated K night shift was obtained by using the ap propriate energy gaps of 2 (0)= $k_B T_c = 5$, 4, and 7 for $CeCu_2Si_2$, UPd_2Al_3 , and $CeCoIn_5$, respectively. Any way, it is demonstrated that qp's decrease to zero a T! 0 due to the form ation of spin-singlet C ooper pair in CeCu₂Si₂, CeCoIn₅, and UPd₂Ab. As a matter d fact, (also T_1) provides a reliable way to deduce in the HF state.

Likewise, in Fig. 3, the K and K_{T_1} in UPt₃ are estimated to be very large, which are compatible with the previous estimates both by the C logston-Jaccarino plot and the high-T Curie-W eiss thing to the Knight shift.³¹ A lso those in UN i₂A k are comparable to the values in UPd2Ab. Sim ilar result is obtained for Sr2RuO₄ in which a calculated value of (K) is in good agreem ent with the spin part of the susceptibility estimated from the C logston-Jaccarino plot reported previously (See Tables II and III).⁷¹ No signi cant reduction in K^{obs} is observed in these compounds, ruling out a possibility for even-parity (spin-singlet) state. The solid lines in the gures are expected if a spin-singlet pairing states were realized with 2 (0)=k $_{\rm B}$ T $_{\rm c}$ = 10, 5, and 4 for UPt $_3$, ³⁰ UNi_2Ak_1 ,⁷² and Sr_2RuO_4 ,⁷¹ respectively. These experimental results reinforce that UPt3, UN iAL, Sr2RuO4 are the odd-parity superconductors, where the d-vector rotates freely as d ? H in the C phase in UPt₃,³¹ while it does as d k c-axis (the odd-parity state with parallel spin pairing lying in the ab plane) in UN $i_{\rm b}$ A $i_{\rm b}^{33}$ and Sr₂RuO₄.⁷¹

To make discussion more clear, we de ne the norm al-

Fig. 3, FIG. 3: (a) T dependence of the H. Hok, Kotshida, Y. K. Waxka ious eld direction (R ef.³¹). (b) T dependence of the ²⁷A – Knight shift for H ? c-axis (R ef.³³). (c) T dependence of the ⁹⁹Ru-Knight shift for H ? c-axis (R ef.⁷¹). The solid lines in both gures are calculations using the Som m erfeld coe cient $_{el}$ for a d-wave singlet E $_{1g}$ m odel (see x 6.1). H ere we assum e $_{eff}$ 1:73 B for U-based HFS's (for details, see x 3).

ized residual susceptibility at T ! 0 as

$$\frac{(T_c) \qquad ^{obs}}{(T_c)} , \frac{K (T_c) K^{obs}}{K (T_c)}; \qquad (29)$$

where we assume $K^{obs} = (A_{hf}=N_{A B})^{obs}$. In Fig. 4, the residual susceptibility ratio (%)= ((T_c)

 $^{\rm obs})=~(T_{\rm c})$ is plotted against . Note that is almost zero (or below zero) for $C\,eC\,u_2\,Si_2$, $C\,eC\,oIn_5$, and UP d_2A l_3, ensuring that the $^{\rm qp}$ in these compounds decreases down to nearly zero at T $\,!\,$ 0 regardless of the crystal direction. Together with the fact that $1=T_1$ / T 3 below T_c , which excludes the s-wave BCS state, a d-wave type anisotropic superconducting state is realized in $C\,eC\,u_2Si_2$, $C\,eC\,oIn_5$, and UP d_2A k.

By contrast, 100 (%) for UPt and UN iA b gives

FIG 4: Normalized residual susceptibility at T ! 0 de ned as = ((T_c) ^{obs}) = (T_c) plotted against (T_c) which is related to the quasi-particle susceptibility as ^{qp} (T_c) ' (T_c) . For UPt₃, data points **Weireu** (Sikshietzey'. Kiratik e values in B-phase.

evidence for an odd-parity (spin-triplet) superconducting state. It was reported that K ^{obs} unchanges across T_c in UBe₁₃³⁴ and URu₂Si₂ as well.³⁵ A lthough an odd-parity pairing state is most likely for URu₂Si₂ and UBe₁₃ from the present analyses, further precise m easurements for high-quality single crystalline sam ples are desirable. A lso the present analysis is applied to Sr₂RuO₄, reinforcing that it is the spin-triplet superconductor.^{70,71}

B. Comments on quasi-particle susceptibility in $\label{eq:commutative} U\; \text{Pt}_3$

Here we discuss the quasi-particle susceptibility in UPt₃. In the previous paper,³² we reported that the obs c value of b 1 10^4 em u/m ole is two orders ofm agnitude sm aller than the value ofm easured susceptibility which is comparable with the present estimates, and T_1 . Fig. 5 shows the T dependence of the ¹⁹⁵Pt Knight shift (195 K) in UPt₃ at various magnetic elds.³² As seen in the gure, when the eld strength is decreased, the K $_{\rm c}^{\rm obs}$ for the c-axis (F ig. 5(c)) and K $_{\rm b}^{\rm obs}$ for the baxis (Fig. 5(b)) decrease across T_c at H < 5 kO e and $H < 2.3 \text{ kOe, respectively. By contrast, } K_a^{\text{obs}}$ (Fig. 5(a)) unchanges $across T_c$ down to the lowest eld of H = 1.764 kOe.Remarkably, 195 K depends on the strength of magnetic eld and its crystal orientation. These results cannot be explained by the even-parity (spin-singlet) pairing m odel at all, but is consistent with the odd-parity (spintriplet) one.32

In order to discuss the quasi-particle susceptibility in UPt₃ within the present model, we focus again on the NMR relaxation behavior. It should be noted that $1=T_1$ is enhanced in the HF state via the transverse component of dynam icalm agnetic susceptibility which is also responsible for the mass enhancement.^{57,58} In most uranium compounds except UPd₂A l₃,⁷³ it is widely believed that a 5f² con guration may lead to a non-K ram ers ground

state. For the HF state involving only a singlet CEF ground state, however, $1=T_1$ may not be enhanced, as mentioned in x 3-1. The fact that $1=T_1$ is enhanced in HFS's suggests that the K ram ers doublet or magnetic CEF ground state is responsible for the form ation of HF state, associated with more itinerant nature of uranium 5f electrons than of cerium 4f electrons. In this context, the reason why the reduction of ^{obs} in the SC state is so sm all may be ascribed to the incom plete lock of d-vector to the crystal, that is, the spin degree of freedom of the C ooper pairs is not always com pletely locked to the crystal axis. This suggests that the K night shifts for K $_{\rm b}^{\rm obs}$ and K $_{\rm c}^{\rm obs}$ decrease markedly at further lower elds. The ¹⁹⁵K night shift measurements at elds lower than 1.7 kO e are needed to check this.⁷⁶

FIG.5: Tem perature dependence of the 195 K night shift in UPt₃ at various magnetic elds for (a)H k a, (b)H k b, (c)H k c (Ref.³²). A rrows show $T_{\rm c1}$ and $T_{\rm c2}$.

M eanwhile, recent theoretical studies proposed that the origin of the tiny reduction of ^{qp} is possible to be explained by assuming that the U (5f²)-derived non-Kramers singlet CEF ground state is hybridized with conduction electrons.^{74,75} It was argued that the qp for a singlet CEF ground state is not enhanced, whereas the DOS of quasi-particles is enhanced via the on-site correlation e ect giving rise to the heavy-Ferm i liquid behavior.⁷⁴ It was predicted qualitatively that the NMR $1=T_1$ is enhanced by an order of $1=T_{\kappa}^2$, while qp is not enhanced by correlation e ect. 75 Unfortunately no direct evidence for the CEF splitting in uranium compounds prevents the com plete understanding of the HF state for the 5f² con guration. Further quantitative discussions in theory in addition to experimental eorts are needed to test whether or not this theoretical model is applicable to UPt_3 as a realistic model. Anyway, the physical properties of the heavy-Ferm ion having a singlet CEF ground state should be addressed by both experim ental and theoretical works in future.

TABLE III: Reduction of the susceptibility $e^{obs} = (N_{A-B} = A_{hf}) K_{P} e^{bs} = T ! 0K$ for various heavy fem ion superconductors. The calculated e ective susceptibility, $e^{qp} = R_{T_c}$ and $r_1 e^{qp} K ()$, by using the relation of $r_1 = (N_{A-B} = A_{hf})K r_1$ assuming $A_{hf} (q) = A_{hf}$. Here we assume $e_{ff} = 1.73 R_{B}$ for U-based HFS's (see x 3). For UPt₃, the respective e^{obs} 's for C and B-phases are listed. The Van V leck susceptibility is calculated from $v_V = e^{obs} (T_c)$. c's are the spin suceptibilities for pure m etals.

VII. CONCLUDING REMARKS

We have presented how the spin susceptibility ^{qp} of quasi-particles in the HFS's is reasonably estimated within the fram ework of the Ferm i-liquid theory, focusing on the NMR and speci c-heat results. The present analysis for the K ram ers doublet CEF ground state has provided two important results on the HF superconductivity:

- 1. In the norm al state, using the value of $T_1T = const$, and the T-linear coe cient $_{el}$ in speci c heat, the respective values, K $_{T_1}$ and K , are related to the quasi-particle K night shift K $^{\rm qp}$. The quasi-particle K orringa relation was found to be valid far below T_K in the HFS's. For U-based HF superconductors, it was expected that any signi cant wave-num ber dependence would be absent in low-lying excitations. Thism eans that the on-sight correlation (U) m ight be responsible not only for the form ation of the HF state but also for the occurrence of HF superconductivity.
- 2. In the superconducting state, for $CeCu_2Si_2$, $CeCoIn_5$ and UPd_2Al_3 , the spin part in the K night shift deduced from K or K_{T_1} is in excellent agreement with the reduction in the observed K night shifts K^{obs} below T_c , giving unambiguous evidence that the heavy quasi-particles form the spinsinglet C coper pairs. By contrast, based on the present analyses, UPt_3 and UNi_2Al_3 are concluded to belong to a class of odd-parity (spin-triplet) pairing state.

The present NMR analysis has shed light on the sem iquantitative estim ate for the quasi-particles susceptibility in the HF system s. Especially from the present analysis based on the Ferm i-liquid theory, it is suggested that the renorm alized HF ground state has a K ram ers degeneracy through the c f m ixing even for U-based HFS's. However, we are still at a long way from a m icroscopic understanding how to represent the heavy-Ferm i liquid state enhanced through the hybridization with a singlet CEF ground state. It is needed to be addressed by further experimental and theoretical e orts in future.

A cknow ledgm ents

W e are grateful to K . A sayam a and G .- q. Zheng for useful discussions and for technical help with NMR measurem ents which were done at 0 saka University. We are also grateful to N.K im ura, E.Yam am oto, Y.Haga, K. M aezawa, Y. O nuki for providing the crystals of UPt_3 , and to C.Geibel, F. Steglich, N. Aso, and N. K. Sato for providing CeCu₂Si₂, UPd₂A k and UN kA k. A lso we are grateful to Y. Maeno for providing Sr₂RuO₄. We would like to thank K.M iyake, H.Kohno, H.Ikeda, H. Kusunose, K. Yam ada, and H. Kontani for theoretical comments and discussions. We thank J.Flouquet for valuable comments. H.T.thanks Y.Kohori for useful comm ents on ${\tt UR}\,u_2\,{\tt Si}_2$ and ${\tt CeC}\,o{\tt In}_5$, and ${\tt M}$. Sera for helpful discussions. This work was supported by Grant-in-Aid for COE Reserach (Nos. 10CE2004 and 13CE2002) from the M inistry of Education, Sport, Science and Culture in Japan.

- 65 ^{9}Be hyper ne eld for Be(II) site is anisotropic, and anisotropic hyper ne elds were obtained as A $^{a}_{\rm hf}$ = 414, A $^{b}_{\rm hf}$ = 147, A $^{c}_{\rm hf}$ = 874 O e/ $_{\rm B}$ for a single crystal UBe $_{13}$ Ref. 64]. On the other hand, the T dependence of NMR relaxation rate 1=T1 was measured for polycrystal UBe $_{13}$ Ref. 56]. In the present analysis, we tentatively used the average value of A $_{\rm hf}$.
- ⁶⁶ If we assume $R_{T_c} = 2$, ^{qp} becomes comparable to $^{obs}(T_c)$, i.e., $_{VV}$ 0. This is hard to consider for the HFS's.
- ⁶⁷ G.E.Volovik, and L.P.Gor'kov, Sov. Phys. JETP, 61 (1985) 843.
- ⁶⁸ As for UPd₂A b, the electronic con guration is considered to be 5f³ and there exist two rather independent electron subsystem s of 5f character [Ref.⁷³]: one of which is identi ed with the itinerant heavy quasiparticle system that responsible for the superconductivity; the other one m ight represent m ore localized 5f² electrons and is responsible for the antiferrom agnetic order. A ctually, the spin part of the K night shift can be divided into two parts of itinerant K ^{GP} and localized K ^{AF} as K ^{obs} (T) K ^{GP} (T) + K ^{AF}, [Ref.²⁷]. In addition, the deduced K night shifts which are equivalent to ^{GP} 1:7 2:0 10 ³ em u/m ole are in quantitative agreem ent with the results of _{SR} 1:7 10 ³ by the ⁺ K night shift R. Feyerherm, et al., Phys. Rev. Lett. 73 (1994) 1849] and _{neutron} 2:14 10 ³ em u/m ole by

the polarized neutron scattering experim ent [L.Paolasini, et al, J.Phys.Cond.M ater.5 (1993) 8905].
