$W$ e report neutron scattering $m$ easurem ents of the spectrum ofm agnetic excitations in the stripe-ordered phase of $\mathrm{La}_{2} \times \mathrm{Sr}_{\mathrm{x}} \mathrm{N}$ i $\mathrm{O}_{4}$ ( $\mathrm{x}=0.275$ and 1/3). The propagating spin excitations follow a sim ilar dispersion relation for the tw o com positions, but the line widths are broader for $\mathrm{x}=0.275$ than for $\mathrm{x}=1=3$.

It is now well established that charge carriers doped into antiferrom agnets tend to segregate into paralleldom ain w alls separating regionsw ith antiferrom agnetic (AF) order of the host spins. T his so-called stripe ordering is observed in m em bers of the cuprate fam ily of superconductors [1] $[1]$, m aking it an exciting eld for basic research.

The stripe modulation of spin and charge has been characterized extensively in the layered
 is the level of hole doping. Interest is now tuming to stripe dynam ics. Recently, we reported tw o separate neutron inelastic scattering studies of the $m$ agnetic excitations in the stripe phase
 cases we observed propagating spin-w ave $m$ odes throughout the $B$ rillouin zone, w ith a maxim um energy of $80\{85 \mathrm{meV}$.
$T$ he case of $x=1=3$ is special in that the periodicities of the charge and $m$ agnetic superlattioes are the sam $e$ and are com $m$ ensurate $w$ th the host lattice. This leads to a very stable stripe order, w th a relatively high ordering tem perature of 200 K and an in-plane correlation length ofseveral

[^0]hundred A $[\overline{1}+1$. H ere w e com pare them agnetic excitation spectrum in crystals w ith $x=0.275$ and $x=1=3$. $T$ hese crystals have sim ilar stripe correlation lengths, but at $x=0: 275$ the spin and charge periodicities are not the sam e and are not com $m$ ensurate $w$ th the host lattioe.
$N$ eutron inelastic scattering $m$ easurem ents werem ade on the M AP S chopper spectrom eter at the IS IS Facility. The single-crystal sam ples w ere m ounted in a closed-cycle refrigerator and aligned w ith the caxisparallelto the incident beam direction. Scattered neutrons were recorded in large banks of position-sensitive detectors. W e analyzed the spectra by $m$ aking a series of constantenergy slices and projecting the intensity on to the $(\mathrm{h} ; \mathrm{k} ; 0)$ reciprocal lattioe plane. T he c com ponent of the scattering vector is unim portant as there are no m easurable spin correlations along the c axis in the range of energies probed.
$T$ he diagonal stripe pattem in $\mathrm{La}_{2}{ }_{x} \mathrm{Sr}_{\mathrm{x}} \mathrm{N}$ io ${ }_{4}$ is $t w$ inned, $w$ th stripes either parallel to the $[1 ; 1 ; 0]$ or $[1 ; 1 ; 0]$ directions of the tetragonal lattice (œell param eter $a=3: 8 \mathrm{~A}$ ). These are described by $m$ agnetic ordering $w$ ave vectors $\left(\frac{1}{2} ; \frac{1}{2} ; 1\right)(; ; 0)$ and $\left(\frac{1}{2} ; \frac{1}{2} ; 1\right)(; \quad ; 0)$, respectively, where ' $n_{h}=2$. In our sam ples we observed an equal population of the tw in dom ains.

Figure 1. C onstant-energy scans at $E=40 \mathrm{meV}$ through the $m$ agnetic zone centres in stripe-ordered $\mathrm{La}_{2}{ }_{\mathrm{x}} \mathrm{Sr}_{\mathrm{x}} \mathrm{N}$ iO $4 \quad(\mathrm{x}=0.275$ and $1 / 3)$. The scans run parallel to the stripe direction. T he lines are ts to G aussian peak pro les.

Figure ${ }_{1}^{11}$ shows scans at an energy of 40 m eV through the $m$ agnetic zone centres $Q_{m}=$ $(0: 35 ; 0: 35 ; 1)$ for $x=0: 275$ and $Q_{m}=(1=3 ; 1=3 ; 1)$ for $x=1=3, w$ th $l^{\prime} 5$ in both cases. The peaks correspond to spin waves propagating parallel to the stripe direction. The positions of the spinw ave peaks are sim ilar for both crystals, but the peaks are m uch broader for $\mathrm{x}=0.275$ and only just resolved. At low er energies the widths of the $x=0: 275$ spin wave peaks decrease, but are al$w$ ays greater than for $x=1=3$.

By perform ing Gaussian ts to scans with di erent energies we determ ined the twodim ensionalspin-w ave dispersion. T he dispersion perpendicular to the stripe direction is show $n$ in F ig. only be obtained for energies above 30 meV . In this energy range the dispersion for the tw o crystals is sim ilar, and consistent w ith that found in
 30 meV , and these will be discussed elsew here.

Perhaps the $m$ ost interesting result from this study is the fact that the spin excitations of the

$F$ igure 2. Spin wave dispersion perpendicular to the stripe direction in $\mathrm{La}_{2} \times \mathrm{Sr}_{8} \mathrm{~N}$ io ${ }_{4}$. T he points at zero energy are from the $m$ agnetic order $B$ ragg peaks.
$\mathrm{x}=0.275$ phase possess a signi cant intrinsic w idth which increases w ith energy, w hereas those of $x=1=3$ do not. Rem em ber that both com positions exhibit very long range stripe order.

It is possible that the robustness of the $\mathrm{x}=1=3$ stripes is due to a strong pinning of the com $m$ ensurate stripes to the lattice. On the other hand, a clear anom aly has been found near $15\{20 \mathrm{~m} \mathrm{eV}$ in the spin excitation spectrum of $x=1=3$ ్ㅓㄴ]. $T$ his $m$ ay be due to som e kind of resonant spin-charge coupling, and investigation of this energy range in the $x=0: 275$ sam ple w ill be of interest.
