# A nom alous fundam entaldiagram $s$ in tra $c$ on ant trails 

A ndreas Schadschneider ${ }^{1}$, D ebashish C how dhury ${ }^{2}$, A lexander John ${ }^{1}$, and $K$ atsuhiro $N$ ishinari ${ }^{3}$<br>${ }^{1}$ Institut fur Theoretische Physik, U niversitat zu K oln, $50937 \mathrm{~K} \circ \mathrm{ln}, \mathrm{Gem}$ any, [as,aj]@thp.uni-koeln.de<br>${ }^{2}$ D epartm ent of P hysics, Indian Institute of Technology, $K$ anpur 208016, India, debch@iitk.ac.in<br>${ }^{3}$ D epartm ent of A pplied $M$ athem atics and Inform atics, $R$ yukoku U niversity, Shiga 520-2194, Japan, knishi@rins.ryukoku.ac.jp

A bstract. $M$ any insects like ants com $m$ unicate chem ically via chem otaxis. $T$ his allow $s$ them to build large trail system $s$ which in $m$ any respects are sim ilar to hum an-build highw ay netw orks. U sing a recently proposed stochastic celhular autom aton m odelwe discuss the basic properties of the tra $c$ ow on existing trails. Surprisingly it is found that in certain regim es the average speed of the ants can vary non $m$ onotonically $w$ ith their density. This is in sharp contrast to highw ay tra c. The observations can be understood by the form ation of loose chusters, i.e. space regions of enhanced, but not $m$ axim al, density. W e also discuss the e ect of counter ow on the trails.

## 1 Introduction

The occurance oforganized tra c [rnin is not only restricted to hum an societies. P rom inent exam ples ofself-organized $m$ otion in biology are herding, ocking and
 have $m$ any sim ilarities $w$ th highw ay netw orks tid].

A nts com $m$ unicate $w$ th each other by dropping a chem ical (generically called pherom one) on the substrate as they $m$ ove forw ard $\left[9_{11}^{1} 0_{1}^{1} 111_{1}^{1}\right]$. A though we cannot sm ell it, the trail pherom one sticks to the substrate long enough for the other follow ing sni ng ants to pick up its sm ell and follow the trail. This process is called chem otaxis $\left[\underline{Z}_{1}\right]$. A nt trails $m$ ay serve di erent purposes (trunk trails, $m$ igratory routes) and $m$ ay also be used in a di erent way by di erent species. $T$ herefore onew ay trails are observed as well as trails w ith counter ow of ants.

In the follow ing we w ill not discuss the process of trail form ation itself. T h is has been studied in the past (see e.g. [12 assum e the existence of a trail netw ork that is constantly reinforced by the ants. Focussing on one particular trail it is natural to assum $e$ that the $m$ otion of the ants is one-dim ensional.

In tra c ow interactions betw een the vehiclestypically lead to a reduction of the average velocity $v$. $T$ his is obvious for braking $m$ aneouvers to avoid crashes. Therefore v ( ) decreasesw ith increasing density ${ }_{1}^{\overline{11}} \boldsymbol{1}$ In the follow ing wew ill show

[^0]that this can be di erent for ant-trails. E ven though due to the sim ilar velocity of the ants overtaking is very rare, which im plies that a description in term s of an exclusion process is possible, the presence of the pherom one e ectively leads to an enhancem ent of the velocity.
$W$ e just brie y $m$ ention that sim ilar ideas can be applied to the description of pedestrian dynam ics. In $\left[{ }^{-1}, 1\right]$ ] $]$ we have developed a pedestrian $m$ odelbased on virtual chem otaxis. T he basic principles are very sim ilar to the ant-trailm odel introduced below. H ow ever, the m otion in pedestrian dynam ics is essentially two-dim ensional.

## $2 \mathrm{D} e \mathrm{n}$ ition of the m odel

In $[17]$ ind of a stochastic cellular autom aton (C A), which $m$ ay be interpreted as a m odel of uni-directional ow in an ant-trail. Asmentioned in Sec. ${ }_{1}^{11}$ we do not want to address the question of the em ergence of the ant-trail [2d, but focus on the tra cofants on a trailw hich has already been form ed. T hem odelgeneralizes the asym $m$ etric sim ple exclusion process (A SEP ) [12 by taking into account the e ect of the pherom one.

The ASEP is one of the sim plest exam ples of a system driven far from equilibrium. Space is discretized into cells that can be occupied by at most one particle. In the totally asym $m$ etric case (TA SEP ) particles are allow ed to $m$ ove in one direction only, e.g. to the right. If the right neighbour site is em pty a particle hops there w ith probability q. For parallel (synchronous) dynam ics this is identical to the lim it $\mathrm{V}_{\mathrm{m}} \mathrm{ax}=1$ of the N agel-Schreckenberg $(\mathbb{N}$ aSch $) \mathrm{m}$ odel $\left.{ }^{[2} \mathrm{m}_{1}^{\prime}\right]$ w th braking probability $\mathrm{p}=1 \quad \mathrm{q}$.

In our m odel of uni-directionalant-tra $c$ the ants $m$ ove according to a rule which is essentially an extension of the TASEP dynam ics. In addition a second
eld is introduced which models the presence or absence of pherom ones (see Fig. ' $\underline{1}_{1}^{\prime \prime}$ ) . The hopping probability of the ants is now modi ed by the presence of pherom ones. It is larger if a pherom one is present at the destination site. Furtherm ore the dynam ics of the pherom ones has to be speci ed. They are created by ants and free pherom ones evaporate with probability f. A ssum ing periodic boundary conditions, the state of the system is updated at each time step in two stages (see Fig. ${ }_{1}^{111}$ ). In stage I ants are allowed to move while in stage II the pherom ones are allow ed to evaporate. In each stage the stochastic dynam ical rules are applied in parallel to all ants and pherom ones, respectively.

## Stage I: M otion of ants

A $n$ ant in a cell cannot $m$ ove if the cellim $m$ ediately in front of it is also occupied by another ant. H ow ever, when this cell is not occupied by any other ant, the probability of its forw ard $m$ ovem ent to the ant-free cell is $Q$ or $q$, depending on whether or not the target cell contains pherom one. Thus, $q$ (or $Q$ ) w ould be the average speed of a free ant in the absence (or presence) of pherom one. To be consistent with real ant-trails, we assum e $q<Q$, as presence of pherom one
state at time t

stage I

stage II

state at time $t+1$

Fig.1. Schem atic representation of typical con gurations of the uni-directional anttra c model. The symbols indicate the presence of pherom one. This gure also illustrates the update procedure. Top: C on guration at tim et, i.e. before stage I of the update. The non-vanishing probabilities of forw ard $m$ ovem ent of the ants are also shown explicitly. M iddle: C on guration after one possible realisation of stage I. Two ants have $m$ oved com pared to the top part of the gure. T he open circle with dashed boundary indicates the location where pherom onew illbe dropped by the corresp onding ant at stage II of the update schem e. A lso indicated are the existing pherom ones that $m$ ay evaporate in stage II of the updating, together $w$ ith the average rate of evaporation. B ottom: C on guration after one possible realization of stage II.T w o drops of pherom ones have evaporated and pherom ones have been dropped/reinforced at the current locations of the ants.
increases the average speed.

## Stage II: Evaporation of pherom ones

Trail pherom one is volatile. So, pherom one secreted by an ant will gradually decay unless reinforced by the follow ing ants. In order to capture this process, we assum e that each œell occupied by an ant at the end of stage I also contains pherom one. On the other hand, pherom one in any ant-free' œll is allowed to evaporate; this evaporation is also assum ed to be a random process that takes place at an average rate of $f$ per unit time.

The total am ount of pherom one on the trail can uctuate although the total num ber $N$ of the ants is constant because of the periodic boundary conditions. In
the tw o special cases $f=0$ and $f=1$ the stationary state of the $m$ odelbecom es identical to that of the TASEP w ith hopping probability $Q$ and $q$, respectively.

For a theoretical description of the process we associate tw o binary variables $S_{i}$ and $i w$ th each site i. $S_{i}$ is the occupation number of ants and takes the value 0 or 1 depending on whether the cell $i$ is em pty or occupied by an ant. Sim ilarly, $i$ is the occupation num ber of the pherom ones, i.e. $i=1$ if the celli contains pherom one; otherw ise, $i=0$. Thus, we have tw o subsets of dynam ical variables in this $m$ odel, nam ely, fS (t)g fS $\mathrm{S}_{1}(\mathrm{t}) ; \mathrm{S}_{2}(\mathrm{t}) ;::: ; \mathrm{S}_{\mathrm{i}}(\mathrm{t}) ;::: ; \mathrm{S}_{\mathrm{L}}(\mathrm{t}) \mathrm{g}$ and
 tim e step $t+1$ is obtained using the full inform ation (fS ( t ) $g ; f(\mathrm{f}) \mathrm{g}$ ) at timet. In stage II only the subset $f$ ( t$) \mathrm{g}$ is updated so that at the end of stage II the new con guration ( $f$ S $(t+1) g ; f(t+1) g$ ) at timet+1 is obtained.
$T$ he rules can be written in a com pact form as the coupled equations

$$
\begin{gather*}
S_{j}(t+1)=S_{j}(t)+\operatorname{minf}_{j 1}(t) ; S_{j 1}(t) ; 1 \quad S_{j}(t) g \\
\operatorname{minf} j(t) ; S_{j}(t) ; 1 \quad S_{j+1}(t) g ;  \tag{1}\\
j(t+1)=\operatorname{maxfS}_{j}(t+1) ; \operatorname{minf}_{j}(t) ; j(t) g g_{i} \tag{2}
\end{gather*}
$$

where and are stochastic variables de ned by $j(t)=0 w$ ith the probability $f$ and $j(t)=1 w$ th $1 \quad f$, and $j(t)=1 w$ th the probability $p=q+\left(\begin{array}{ll}Q & q+1(t)\end{array}\right.$ and $j(t)=0 w$ th $1 \quad p$. This representation is useful for the developm ent of approxim ation schem es.

## 3 Fundam ental diagram for uni-directionalm otion

In vehicular tra $c$, usually, the inter-vehicle interactions tend to hinder each other'sm otion so that the average speed of the vehicles decreases m onotonically w ith increasing density. This can be seen in $F$ ig. diagram of the NaSch m odel w ith $\mathrm{V}_{\mathrm{m}}$ ax $=1$ (or the TASEP w ith parallel updating) is show $n$ for di erent hopping probabilities. $N$ ote also the particle-hole symm etry of the ow that satis es $\mathrm{F}_{\mathrm{NS}}()=\mathrm{F}_{\mathrm{NS}}(1 \quad)$. Explicitly it is given by [25]

$$
\begin{equation*}
\left.\mathrm{F}_{\mathrm{NS}}()=\frac{1}{2}^{\mathrm{h}} \quad \mathrm{p} \overline{1}_{1}^{4 \mathrm{q}_{\mathrm{NS}}(1)}\right)^{i} \tag{3}
\end{equation*}
$$

$w$ here $q_{v s}=1 \quad p w$ th $p$ being the braking probability. Here $=N=L$ is the density of vehicles and $L$ the num ber of cells.

In contrast, in our m odel of uni-directional ant-tra c the average speed of the ants varies non-m onotonically $w$ ith their density over a $w$ ide range of m all values of $f$ (see Fig. (2, in ) because of the coupling of their dynam ics $w$ th that of the pherom one. This uncom $m$ on variation of the average speed gives rise to the unusual dependence of the ux on the density of the ants in our uni-directionalant-tra cm odel ( F ig. $\bar{W}$. Furtherm ore the $u x$ is no longer particlehole sym $m$ etric.

Fig.2. The average speed (left) and the ux (right) of the ants, in the unidirectional ant-tra c m odel, are plotted against their densities for the param eters $\mathrm{Q}=0: 75 ; q=0: 25$. The curves correspond to $\mathrm{f}=0: 0001$ ( ) , 0:0005 ( ) , 0:001 ( ) , $0: 005(\mathrm{~N}) 0: 01(\mathrm{)}, 0: 05(/), 0: 10(5), 0: 25(+)$. In both graphs, the cases $f=0$ and $f=1$ are also displayed by the upperm ost and low erm ost curves (w thout points); these are exact results corresponding to the TASEP or $N$ aSch $m$ odel $w$ ith $v_{m}$ ax $=1$ and hopping probability $Q$ and q, respectively. C urves plotted w ith lled sym bols have unusual shapes.

Fig.3. N um erical results for the probabilities of nding an ant ( ), pherom one but no ant ( ) and nothing ( ) in front of an ant are plotted against density of the ants. The param eters are $f=0: 005$ (left) and $f=0: 01$ (right).

## 3.1 "Loose" cluster approxim ation (LCA)

H ow can the unusualdensity-dependence of the average velocity be understood? U sing $m$ ean- eld-type theories that im plicitly assum e a hom ogeneous stationary state does not allow to reproduce the sim ulation results in a satisfactory way [ $\left.1 \overline{1}^{1}\right]$. This indicates that the stationary state is characterized by som e sort of clustering. This is con $m$ ed by considering the probabilities of nding an ant $\left(\mathrm{P}_{\mathrm{a}}\right)$, pherom one $\left(\mathrm{P}_{\mathrm{p}}\right)$ and nothing ( $\mathrm{P}_{0}$ ) in front of a cell occupied by an ant. Typical results from com puter sim ulations are shown in $F$ ig. $\overline{\mathrm{N}_{1}}$.

O ne can distinguish three di erent regions. $\backslash$ Region $1 "$ is characterized by the at part of the curves in Fig. ${ }_{1} 1$ low density of the ants, the probability of nding an ant in front of another is

Fig. 4 . (left) Schem atic explanation of the loose cluster. $H$ is the hopping probability of ants inside the loose cluster and $h$ is that of the leading ant. (right) $T$ he stationary loose cluster. T he average gap betw een ants becom es $h=H$, which is irrelevant to the density of ants.
quite high. T his im plies the fact that ants tend to form a cluster. On the other hand, cluster-size distributions obtained from com puter sim ulations show that the probability of nding isolated ants are alw ays higher than that of nding a cluster of ants occupying nearest-neighbor sites [1] [1]. These two apparently contradictory observations can be reconciled by assum ing that the ants form $\backslash$ loose" clusters in the region 1 . T he term \loose" m eans that there are sm all gaps in betw een successive ants in the cluster, and the cluster looks like an usual com pact cluster if it is seen from a distance ( $F$ ig. '(1/1). In other words, a loose cluster is just a loose assem bly of isolated ants that corresponds to a space region $w$ ith density larger than the average density , but sm aller than the maxim al density ( = 1) of a com pact chuster.

Let us assum e that the loose cluster becom es stationary after su cient tim e has passed. Then the hopping probability of all the ants, except the leading one, is assum ed to be $H$, while that of the leading one is $h$ (see $F$ ig. ${ }_{\underline{-1}}^{4}$ ). The values of $H$ and $h$ have to be determ ined self-consistently. If $f$ is $s m$ all enough, then H willbe close to $Q$ because the gap between ants is quite sm all. On the other hand, if the density of ants is low enough, then $h \mathrm{w}$ illbe very close to $q$ because the pherom one dropped by the leading ant w ould evaporate when the follow ing ant arrives there.

The typical size of the gap betw een successive ants in the cluster can be esti$m$ ated [ [1d] by considering a sim ple tim e evolution beginning $w$ ith a usual com pact cluster ( w th localdensity $=1$ ). The leading ant w illm ove forw ard by one site over the tim e intervall=h.T his hopping occurs repeatedly and in the interval of the successive hopping, the num ber of the follow ing ants which willm ove one step is $H=h$. Thus, in the stationary state, strings (com pact clusters) of length $\mathrm{H}=\mathrm{h}$, separated from each other by one vacant site, w ill produced repeatedly by
 dependent of their density. Interestingly, the density-independent average gap in the LCA is consistent $w$ ith the at part (i.e., region 1) observed in com puter sim ulations ( F ig.

Beyond region 1, the e ect of pherom one of the last ant becom es dom inant. $T$ hen the hopping probability of leading ants becom es large and the gap becom es wider, which will increase the ow. We call this region as region 2, in which $\backslash$ looser" clusters are form ed in the stationary state. It can be characterized by a negative gradient of the density dependence of the probability to nd an ant

C onsidering these facts, we obtain the follow ing equations for h and H :
where $l$ is the length of the cluster given by $l=L+\left(\begin{array}{ll}L & 1\end{array}\right) \frac{h}{H} . T$ hese equations can be applied to the region 1 and 2.

The total ux in this system is then calculated as follows. T he e ective density $e$ in the loose cluster is given by $e=\frac{1}{1+h=H}$. Therefore, considering the fact that there are no ants in the part of the length $L \quad l$, the total $u x F$ is

$$
\begin{equation*}
F=\frac{l}{L} f(H ; e) ; \tag{5}
\end{equation*}
$$

where $\mathrm{f}(\mathrm{H}$; e) is given by

$$
\begin{equation*}
\left.\mathrm{f}(\mathrm{H} ; \mathrm{e})=\frac{1}{2} \quad 1 \quad \mathrm{P} \overline{1} \overline{4 H} \text { e (1 e }\right): \tag{6}
\end{equation*}
$$

A bove the density $=1=2$, ants are assum ed to be uniform ly distributed such that a m ean- eld approxim ation works well $\left[1 \bar{L}_{1}^{\prime}\right]$. W e call this region as region 3. $T$ hus we have three typical regions in this model. In region 3, the relation $H=h$ holds because all the gaps have the sam e length, i.e. the state is hom ogeneous. T hus h is determ ined by

$$
\begin{equation*}
{\frac{\mathrm{h} \mathrm{q}^{\mathrm{q}}}{\mathrm{q}}}^{\mathrm{h}}=(1 \quad \mathrm{f})^{1 / 1} \tag{7}
\end{equation*}
$$

which is the sam e as our previous paper, and ux is given by $f(h$; ). It is noted that if we put $=1=2$ and $H=h$, then ( $(\underline{4})$ coincides w ith $\left(\overline{7}_{1}\right)$.

In region 1 we can sim plify the analysis by assum ing $h=q$ in ( $\overline{1} \mathbf{1})$. $T$ hen the ux-density relation becom es linear. N um erical results for regions 1 and 2 can be obtained by solving ( $\overline{4} \mathbf{1})$ using the $N$ ew ton $m$ ethod for densities $\quad 1=2$. Above th is value of density, equation $\left[\overline{T_{1}}\right)$ can be used. Together these approxim ations can reproduce the results of the sim ulations rather well [1]

A nother interesting phenom enon observed in the sim ulations is coarsening. At interm ediate tim e usually several loose clusters are form ed ( F ig. . $\mathrm{T}_{1}^{\prime \prime}$ ') . H ow ever,

Fig.5. Space-tim e plots show ing the coarsening process of the loose clusters. T he left part show s the state of a system of $L=1000$ cells and $N=100$ ants at early tim es. $T$ he right part corresponds to the stationary state. $T$ he evaporation probability of the pherom ones is $f=0: 0005$.
the velocity of a cluster depends on the distance to the next cluster ahead. O bviously, the probability that the pherom one created by the last ant of the previous cluster survives decreases with increasing distance. T herefore clusters w ith a sm all headw ay $m$ ove faster than those $w$ ith a large headw ay. This induces a coarsening process such that after long tim es only one loose cluster survives ( F ig. $\cdot$.

## 4 B idirectionalm otion

W e develope a m odel of bi-directional ant-tra c $\left[\frac{1}{2}\right]$ uni-directionalant-tra c described in Sec. $2_{1}^{-1}$ In the m odels ofbi-directionalanttra c the trailconsists of tw o lanes of cells (see F ig. \$\$". T hese tw o lanes need not be physically separate rigid lanes in real space; these are, how ever, conven ient for describing the $m$ ovem ents of ants in tw o opposite directions. In the intial con guration, a random ly selected subset of the ants $m$ ove in the clockw ise direction in one lane while the others $m$ ove counterclockw ise in the other lane. H ow ever, ants are allowed neither to take $U$ tumil nor to change lane. Thus, the ratio of the populations of clockw ise-m oving and anti-clockw ise m oving ants rem ains unchanged as the system evolves with tim e. All the num erical data presented here are for the sym $m$ etric case where equal num ber of ants $m$ ove in the two directions. Therefore, the average ux of outbound and nestbound ants are identical. In all the graphs we plot only the ux of the nestbound ants.
$T$ he rules goveming the dropping and evaporation ofpherom one in the odel ofbi-directional ant-tra c are identical to those in the m odel of uni-directional tra c. The com $m$ on pherom one trail is created and reinforced by both the outbound and nestbound ants. T he probabilities of forw ard $m$ ovem ent of the ants

[^1]

Fig.6. A typical head-on encounter of two oppositely $m$ oving ants in the $m$ odel of bi-directionalant-tra c. This is a totally new process which does not have any analog in the $m$ odel of uni-directional ant-tra $c$.
in the $m$ odel of bi-directional ant-tra $c$ are also natural extensions of the sim ilar situations in the uni-directionaltra c. W hen an ant (in either of the two lanes) does not face any other ant approaching it from the opposite direction the likelihood of its forw ard $m$ ovem ent onto the ant-free cell im m ediately in front of it is $Q$ or $q$, respectively, depending on whether or not it nds pherom one ahead. Finally, if an ant nds another oncom ing ant just in front of it, as show $n$ in F ig. ${ }^{\prime} \mathrm{G}$, it m oves forw ard onto the next cell w th probability K .

Since ants do not segregate in perfectly w ellde ned lanes, head-on encounters ofoppositely $m$ oving individuals occurquite often although the frequency ofsuch encounters and the lane discipline varies from one species of ants to another. In reality, tw o ants approaching each other feel the hindrance, tum by a sm allangle to avoid head-on collision [13] and, eventually, pass each other. At rst sight, it $m$ ay appear that the ants in our $m$ odel follow perfect lane discipline and, hence, unrealistic. H ow ever, that is not true. The violation of lane discipline and head-on encounters of oppositely $m$ oving ants is captured, e ectively, in an indirect $m$ anner by assum ing $K<Q$. But, a left m oving (right-m oving) ant cannot overtake another left-m oving (right-m oving) ant im mediately in front of it in the same lane. It is worth $m$ entioning that even in the lim it $K=Q$ the tra c dynam ics on the two lanes would rem ain coupled because the pherom one dropped by the outbound ants also in uence the nestbound ants and vice versa.

Fig. $\overline{1}=1$ show s fiundam ental diagram $s$ for the two relevant cases $q<K<Q$ and $K<q<Q$ and di erent values of the evaporation probability $f$. In both cases the unusualbehaviour related to a non-m onotonic variation of the average speed w ith density as in the uni-directionalm odel can be observed [19].

A $n$ additional feature of the fiundam ental diagram in the bi-directional anttra c model is the occurrence of a plateau region. This plateau form ation is $m$ ore pronounced in the case $K<q<Q$ than for $q<K<Q$ since they appear for all values of $f$. Sim ilar plateaus have been observed earlier [2] ${ }^{2}$ in m odels related to vehicular tra c where random ly placed bottlenecks slow down the tra c in certain locations along the route. N ote that for $\mathrm{q}<\mathrm{K}<\mathrm{Q}$

F ig. 7. Fundam ental diagram s of the m odel for bi-directional tra c for the cases $\mathrm{q}<$ $\mathrm{K}<\mathrm{Q}$ (left) and $\mathrm{K}<\mathrm{q}<\mathrm{Q}$ (right) for several di erent values of the pherom one evaporation probability $f$. The param eters in the left graph are $Q=0: 75 ; q=0: 25$ and $K=0: 5$. The sym bols , , 4, , , 5, 3 and / correspond, respectively, to $\mathrm{f}=0 ; 0: 0005 ; 0: 005 ; 0: 05 ; 0: 075 ; 0: 10 ; 0: 25 ; 0: 5$ and 1. The param eters in the right graph are $Q=0: 75 ; q=0: 50$ and $K=0: 25$. The symbols , , , 4 ,/ and 5 correspond, respectively, to $\mathrm{f}=0 ; 0: 0005 ; 0: 005 ; 0: 05 ; 0: 5$ and 1 . The inset in the right graph is a m agni ed re-plot of the sam e data, over a narrow range of density, to em phasize the fact that the unusual trend of variation of ux with density in this case is sim ilar to that observed in the case $q<K<Q$ (left). The lines are $m$ erely guides to the eye. In all cases curves plotted w ith led sym bols exhibit non-m onotonic behaviour in the speed-density relation.
(Fig. $\left.I_{1} \overline{7}_{1}(l e f t)\right)$ the plateaus appear only in the tw o lim its $\mathrm{f}!0$ and $\mathrm{f}!1$, but not for an interm ediate range of values of $f$. In the lim it $f!0, m$ ost often the likelihood of the forw ard $m$ ovem ent of the ants is $Q$ whereas they are forced to $m$ ove $w$ th a sm aller probability $K$ at those locationsw here they face another ant im $m$ ediately in front approaching from the opposite direction (like the situations depicted in $F$ ig. ${ }^{(1, \bar{G}) .}$. Thus, such encounters of oppositely $m$ oving ants have the sam ee ect on ant-tra cas bottlenecks on vehicular tra c.

But why do the plateaus re-appear for $\mathrm{q}<\mathrm{K}<\mathrm{Q}$ also in the lim it $\mathrm{f}!1$ ? At su ciently high densities, oppositely moving ants facing each other $m$ ove w ith probability K rather than q . In this case, locations where the ants have to $m$ ove w th the low er probability $q$ w ill be, e ectively bottlenecks and hence the re-appearance of the plateau. A $\mathrm{f} f$ approaches unity there w illbe larger num ber of such locations and, hence, the wider will be the plateau. This is consistent w ith our observation in Fig. $i_{1}^{17}$ (left).

## 5 C onclusions

W e have introduced a stochastic cellular autom aton $m$ odel of an ant trail $\left.\overline{[ } \bar{\eta}_{1}\right]$ characterized by two coupled dynam ical variables, representing the ants and the pherom one. $W$ ith periodic boundary conditions, the total num ber of ants is
conserved whereas the total num ber of pherom ones is not conserved. T he coupling leads to surprising results, especially an anom alous fundam ental diagram . $T$ his anom alous shape of the fundam ental diagram is a consequence of the non$m$ onotonic variation of the average speed of the ants $w$ ith their density in an interm ediate range of the rate of pherom one evaporation.

A sthe reason for this unusualbehaviourw e have identi ed the specialspatiotem poral organization of the ants and pherom one in the stationary state. Three di erent regim es of density can be distinguished by studying appropriate correlation functions. At low densities (region 1) the behaviour is dom inated by the existence of loose clusters which are form ed through the intenplay betw een the dynam ics of ants and pherom one. T hese loose clusters are regionsw ith a density that is larger than the average density , but not $m$ axim al. In region 2 , occuring at interm ediate densities, the enhancem ent of the hopping probability due to pherom one is dom inant. Finally, in region 3, at large densities the m utual hindrance against the $m$ ovem ents of the ants dom inates the ow behaviour leading to a hom ogeneous state sim ilar to that of the NaSch m odel.

Furtherm ore we have introduced a m odel of bi-directional ant-tra c. The tw o $m$ ain theoretical predictions of this $m$ odel are as follow s:
(i) The average speed of the ants varies non-m onotonically with their density over a wide range of rates of pherom one evaporation. T his unusual variation gives rise to the uncom $m$ on shape of the ux-versus-density diagram $s$.
(ii) O ver som e regions of param eter space, the ux exhibits plateausw hen plotted against density.

In principle, it should be possible to test these theoretical predictions experim entally. Interestingly, various aspects of locom otion of individual ants have been studied in quite great detail [31, How ever, tra c is a collective phenom enon involving a large num ber of interacting ants. Surprisingly, to our know ledge, the results published by B urd et al. [3] ${ }^{3}$ ] on the leaf-cutting ant A tta C ephalotes are the only set of experim ental data available on the fundam ental diagram. Unfortunately, the uctuations in the data are too high to $m$ ake any direct com parison w ith our theoretical predictions. N evertheless it should be possible to observe the predicted non-m onotonicity in future experim ents. A simple estim ate shows that the typicalm agnitudes of $f$, for which the non$m$ onotonic variation of the average speed with density is predicted, correspond to pherom one lifetim es in the range from few $m$ inutes to tens ofm inutes. $T$ his is of the sam e order ofm agnitude as the $m$ easured lifetim es of realant pherom ones!

A cknow ledgm ents
